It is, however, impossible to neglect a comparison between the states of diabetic coma and hypoglycæmic collapse, the latter being an entirely novel conception that has come into pathological thought as the result of experience with insulin. The hypoglycæmic collapse is caused by the artificial lowering of the blood-sugar to half its normal level for health, and it is at once relieved by giving sugar. The brain is therefore as sensitive to the withdrawal of sugar as to sudden diminution in its oxygen supply. It may be that one aspect of the picture of diabetic coma is due to the final inability of the brain cells to consume sugar, even though this food be presented to them in abundance in the blood. Insulin might restore their metabolic power, and their functional recovery might conceivably be aided by artificially increasing for a short time the amount of blood-sugar upon which they can commence to feed.

At any rate, whatever the theory, experience has suggested that, in the treatment of diabetic coma with insulin, glucose should be given simultaneously, either by the mouth or by the stomach-tube or even intravenously. The insulin can generally be administered by hypodermic injection. In cases of extreme circulatory collapse, it can be used intravenously without danger. In all cases fluid should at the same time be given, but not much in excess of half a pint every hour, so that the patient on recovery from the coma shall not fall into danger of death from pulmonary oedema.

The scanty experiences quoted suggest that post-surgical coma in diabetics is difficult to treat. Obviously, the best way is to avoid its occurrence altogether by careful preparation of the patient before the operation, dietetic control and insulin being used together to free the urine of ketones and sugar. There is no evidence available upon the course of such prophylactic treatment, or upon how the action of insulin may be influenced by the proceedings connected with surgical operations.

Other complications of diabetes, such as sepsis, tuberculosis, or peripheral neuritis, can presumably be influenced by insulin as favourably as they are by ordinary dietetic control, when the latter succeeds in abolishing glycosuria. But on this aspect of the general malady no evidence has been collected, for the first investigations in British hospitals were restricted to simple, though serious, instances of diabetes.

THE LANCET.

LONDON: SATURDAY, MAY 5, 1923.

THE NEW CURRICULUM.¹

THE medical curriculum, as all our readers know, has been thoroughly revised; as from Jan. 1st, 1923, the students' educational course has been strengthened, simplified, and coördinated. The revision extends from the pre-registration stage of those who intend to join our numbers, through the hospital career, until satisfaction of examiners leads to registration as a practitioner. Sir GEORGE NEWMAN, in a Memorandum addressed to the Minister of Health, provides an explanation which is also a justification of an interesting programme of reform, and the document should be in the hands of all who are interested in education, lay-men as well as medical men and students, so that they may obtain a clear perception of the present training of the doctor; of the defaults which are remedied and of the better opportunities which are provided by the reforms here set out. The Memorandum follows the form of a previous document entitled, "Notes on Medical Education in England," which was published by the Board of Education five years ago. Since that date not only has the whole of the medical curriculum been changed, but new legislation has been introduced to deal with many grave evils in dental practice, new rules have been laid down to ensure practical training in sanitary science, and university clinics have been founded supported by large grants from public money. The Chief Medical Officer of the Ministry of Health deals with all the substantial modifications in medical education which are thus indicated, and shows the objective also of the university clinics, as bringing into the clinical sphere the whole scientific equipment of the medical school, as advancing learning by research, and as doing both these things in intimate coöperation with the work of the ward, the special department, and the laboratory. The Memorandum is deliberately discursive, but reforms cannot be justified until their necessity has been explained, and rules cannot be comprehended unless the situations which they have been devised to meet are made plain. An appendix gives the regulations for the new curriculum which have been laid down by the General Medical Council, enabling the reader to follow the thread of the chapters (though they are quite clearly written); but it is useful to be able at any moment to consult the actual edicts of the Council, which form a syllabus of all stages of professional study, while they also give the necessary information concerning pre-registration examinations.

What we see first in the new curriculum is that the course is planned to be continuous, and this is important as recent developments in medical education have tended to create water-tight departments. Medical excursions into chemistry, physics, and biology have been frequent and free, and along different lines a high degree of exact knowledge has been obtained. But as that knowledge became more elaborate and detailed so did the particular workers along a given line tend to concentrate upon their speciality, until the spirit of coöperation became jeopardised. The

student, who could not be, and never was, expected to follow such studies in their elaboration, was not supplied with the right sort of connecting links between them, so that no general idea of a massed attack upon disease arose in his mind, enabling him to recognise certain work as preventive in its object and certain as therapeutic, one procedure as assisting in diagnosis and another in treatment. He received his instruction in isolated samples from teachers who pursued their bent in isolation. It was to meet this situation that the experiment of university clinics was instituted some three years ago, providing, in the words of Sir CLIFFORD ALLBUTT, "a professoriate; whole-time, or nearly whole-time professors, with technical laboratory, biochemical and pathological, who, with their assistant staff, shall be engaged continually in irrigating our profession from the springs of the pure sciences." The institution of the units illustrates the development of medical education. When the whole of medical education was in the hands of the practising leaders of the profession, the progress made was grand, but with that progress the need of teachers with special equipment arose. The strain upon the physicians and surgeons of the hospitals became too great, for, in addition to educational responsibilities, entailing close knowledge in directions where they themselves were but recent students, they had their duties to patients without the walls of the hospital. The appointment of whole-time or part-time professors, selected for their clinical and teaching power and approved capacity for research, was therefore determined upon, and the innovation embodies the traditional features of the British system of clinical training, while correcting defects that had arisen in that system through its own virtues in promoting our science. The experience of three years has proved the value of the units in correlating medicine and surgery, and in introducing the methods and spirit of research into medical education. The history is too brief to afford material for any dogmatic estimate of results, but that those results will be good may be expected hopefully.

A chapter in the Memorandum deals with the recommendations of the General Medical Council in respect of an improved scheme for the teaching of obstetrics and gynaecology. It is admitted that the arrangements for teaching these subjects to students have not hitherto been comparable with those concerned in the other clinical portions of the curriculum, but no emphasis need be laid upon the fact that effective teaching in this direction is one of the foremost of the student's needs. More than 50 per cent. of the confinements in the country now come under the hands of registered midwives, but that does not alter the need in the slightest, rather it is intensified thereby; for the cases which remain for medical practitioners include those complicated or serious ones where the midwife is compelled by Act of Parliament to summon medical aid. The General Medical Council has now recommended that in addition to courses of systematic instruction in the principles and practice of obstetrics and gynaecology, accompanied by attendances on in-patients and out-patients, every student shall be trained in the observation of ante-natal conditions and the principles of infant hygiene. This is a recognition of the obvious facts that preventive medicine should play a large part in obstetrics, and that in every case of labour there are two patients concerned. Why more stress has not been laid in the past upon such truisms we are left to wonder. But before obstetrics can be taught at the bedside as fully as medicine and surgery are now taught it will be necessary to discover a larger supply of maternity beds. Should we plead

¹ Recent Advances in Medical Education in England. A Memorandum addressed to the Minister of Health by Sir George Newman, Chief Medical Officer of the Ministry and of the Board of Education. H.M. Stationery Office and all Booksellers. 1s. 3d.

that in gynæcology the training of the medical student is adequate, it may fairly be retorted that the subject is not an extensive one. It is in regard to obstetrics that the insufficiency of both the clinical and systematic teaching is crying, and the main reason is that an insufficient number of beds is devoted to the subject in most of our teaching hospitals. Bedside instruction on labour cases ought, moreover, to be the duty of experienced members of the staff of a hospital, a condition which can only be satisfied when the teachers are resident. We have endorsed recently in these columns the widespread view that nothing can be done in the extern department sufficient to teach the student properly, unless it can be combined with training under skilled supervision in lying-in wards. The recommendations of the General Medical Council on the teaching of obstetrics and gynæcology are sound enough, but real effect cannot be given to them until more beds are provided. The point is fully brought out by Sir GEORGE NEWMAN in the Memorandum, which we regard as a highly valuable piece of work. It is a guide to and an explanation of the medical curriculum with a wise and wide commentary upon the regulations; it should be in the hands of all teachers, and students would benefit much by learning from its pages their charted course.

DEATHS UNDER ANÆSTHETICS.

At a recent discussion on Coroners' Inquests at the Royal Society of Medicine, reported last week at length in our columns, Dr. J. H. CHALDECOTT raised a question of interest to many members of the medical profession. Under the Act of 1887 a coroner must hold an inquest "where the dead body of a person is lying within his jurisdiction and there is reasonable cause to suspect that such person has died either a violent or an unnatural death or has died a sudden death of which the cause is unknown." The law thus leaving them an ample latitude in deciding what is reasonable; coroners, it is stated, have evolved the rule of practice that, where a death occurs under an anæsthetic, an inquest is necessary, although where death occurs from a purely surgical operation, an inquest need not be held. Possibly the distinction has been stated in too general terms, since each case must depend on its own peculiar set of facts, and since serious surgical operations are usually associated with anæsthetics. It is, moreover, scarcely profitable to inquire whether death under the surgeon's knife is less "violent or unnatural" than death under an anæsthetic. If, however, we eliminate all mere generalisations and all mere debating points, we find that anæsthetists are undoubtedly disquieted by a feeling that they are summoned to attend at inquests when other practitioners are not. We need not add that neither an anæsthetist nor, indeed, any medical practitioner ought to be harassed in the execution of his delicate duties by visions of sensational headlines in some catch-penny journal or by anticipations of hostile and perhaps ill-inspired cross-examination. The almost immemorial institution of the coroner's inquest does undoubtedly represent a public safeguard which, however witnesses may be misrepresented and misrepresented, in the vast majority of cases reassures the relatives of the deceased and builds up public confidence. No tribunal of scientific experts sitting behind closed doors would carry the same weight with the multitude as the open court of the coroner, where gossip and suspicion are vindicated or refuted and human actions and motives are challenged and defended in an atmosphere which would be wholly uncongenial to pure scientific inquiry. The abolition

of the coronership would involve a change in the law for which we are convinced the country is entirely unprepared. Dr. A. H. BYGOTT failed to carry the Society of Medical Officers of Health with him in his interesting suggestion to substitute for the coroner the county or borough sanitary authority. Without, however, contemplating any revolutionary alteration in a time-honoured institution which has claimed to trace its origin back as far as King ALFRED, we can still discuss how best this ancient office can fulfil its purpose in the days of King GEORGE. The use of ether and chloroform would have justified a most searching inquiry in the days of the Heptarchy; we are still learning about anæsthetics to-day, but their properties are no longer entirely unfamiliar.

The endeavour to avoid the holding of inquests when a death occurs under an anæsthetic in circumstances which demonstrably negative the idea of either negligence or crime, is not a new one. As was mentioned during the discussion on Dr. CHALDECOTT's paper, the subject was reported upon several years before the war. In 1908 the Home Secretary appointed a Committee to inquire into the law of coroners and coroners' inquests. The Committee was presided over by Sir MACKENZIE CHALMERS, and included Sir MALCOLM MORRIS and Dr. (now Sir WILLIAM) WILLCOX. In the course of its activities it specially studied the question of deaths resulting from the administration of anæsthetics, and after examining eminent anæsthetists, surgeons, and physicians (the witnesses including Sir VICTOR HORSLEY and Sir LAUDER BRUNTON), it issued in 1910 a separate report on this aspect of the law relating to coroners. In part the Committee's recommendations dealt with the scandal of the then entirely unchecked administration of drugs. In so far as they led to our present legislation as to dangerous drugs, they bore fruit. Otherwise they were abortive, though it is worth while to recall what the other recommendations were. The Chalmers Committee recommended that every death under an anæsthetic should be reported to the coroner, who, after inquiry, should determine whether the holding of an inquiry was desirable or not. In the case of every death under an anæsthetic the medical certificate should state the fact, whether the anæsthetic was the actual cause of death or not. In the case of every death under an anæsthetic in a hospital or other similar public institution, there should be a scientific investigation into the cause of death conducted by the authorities of the institution. Finally, a small standing scientific committee on anæsthetics should be instituted under the authority of the Home Office, to collect and digest information, report on advances made by the discovery of new anæsthetics or by improvements in administration, to direct research, and to make the resultant information available in convenient form and at small cost to the medical profession. It would be a sensible step to reconstitute the Chalmers Committee and to set it the task of developing its former proposals in the light of more recent knowledge and experience. We think that the suggested inquiry in the case of deaths under anæsthetics might be strengthened and made more independent. What seems to be wanted is that, with the consent of all the interests concerned, a panel of leading pathologists should be appointed from which personnel could be drawn to make prompt and full examination of all such cases of death. We should thus obtain not only in general a valuable collection of scientific data, but also in each particular case a certificated and thoroughly authoritative report which would be available for the use of the coroner.

Such a report would in no way be a substitute for a coroner's inquest, but it would often enable the coroner to form an opinion that no element of crime or of criminal negligence was present and that no further investigation was required. Possibly for greater publicity coroners might evolve a procedure in appropriate cases for recording a merely formal verdict on the lines of the scientific report if satisfied thereby. We do not forget that, as Dr. Z. MENNELL pointed out during the discussion, the machinery for a domestic inquiry at the hospital already is in some cases in operation. This machinery should, we consider, be standardised; the investigation should be entrusted to what we have called a panel of pathologists whose names command universal confidence, and it might be arranged that no member of the panel should investigate a case of death occurring at his own hospital. Some useful procedure could, we are convinced, be devised on these lines by men of good will. Fortunately the subject has from the beginning been discussed without the least ill-will or bitterness. There is no room for foolish suggestions that on the one hand anaesthetists have anything to conceal, or that on the other hand coroners multiply inquests for the sake of fees.

The fundamental facts to be faced are two. The first is that the coroner's inquest as an institution is indispensable; the second is that, though it may not suit him to admit it, the coroner's discretion is well-nigh absolute. If he decides not to hold an inquest, powers do exist by which the High Court can order one to be held, but those powers have hardly ever been employed. Conversely, if he decides to hold an inquest, nobody (except in almost unheard-of cases) has power to prevent him. The coroner is master of the situation, and his authority has, if anything, increased latterly since during the war he was in some degree made independent of his jury. In recognition of these two facts we appeal to the coroners as a body—for they are organised as such—to state their views, to tell us how far they accept the conclusions of the Chalmers Committee, how far some such independent and authoritative report as we have spoken of above would be useful to them, how far they would be willing in appropriate cases to rely upon it. The coroner enjoys the full confidence of the country. We do not think he will forfeit it if in cases where no suspicion of crime arises and where the highest professional opinion can find no scintilla of negligence, he accepts the certificate of such a tribunal as we have indicated and dispenses with further inquiry.

THE STORY OF INSULIN.

THE story of insulin is in three chapters. In the year 1869 PAUL LANGERHANS, a pupil of VIRCHOW, described in his thesis for the Berlin M.D. certain cell-groups irregularly scattered in the pancreas, which have since been known as his islands. On the ground of their structure he suggested the probability of a secretory activity. Becoming phthisical, he did not hold for long the chair of pathological anatomy at Freiburg, was unable to follow up his work, and died before the age of 40 in Madeira. In 1893 EDOUARD LAGUESSE, professor of histology at Lille, first gave expression to the opinion that, whereas the digestive secretion of the pancreatic acini is delivered through the ducts, the islands of Langerhans are entrusted with some endocrine function important for carbohydrate metabolism; and he devoted all his working life to the elaboration of this opinion. Twenty-five years from anatomy to physiology, and it has taken

another thirty years for therapeutics to exploit the physiological suggestion. The tertiary stage of the story was reached last month, when a hospital patient, admitted on the verge of diabetic coma with extreme air-hunger, a blood-sugar reading of 0.33 per cent. and an alveolar CO_2 reading of 1.1 per cent., was restored to comfort within three hours by the administration of 18 units of insulin extracted from bovine islands of Langerhans. For three weeks after this event the patient has continued to enjoy a diet of 33 g. of protein, 105 g. of fat, and 16 g. of carbohydrate, without glycosuria, on a daily intake of 12 units of insulin. Although there are many points regarding the clinical uses of insulin as yet unexplained, as is made clear in the report to the Medical Research Council which we print on p. 905, the fact is undeniable that an internal secretion has been isolated from the pancreas for practical use which has, for better or for worse, a potent effect on the sugar-content of the blood. If the quantity of the available preparation permitted—which it does not—insulin might be freely used by any diabetic subject, in the picturesque American phrase, for a carbohydrate jag. Even under the carefully controlled conditions of clinical research insulin has resulted in reducing the blood-sugar to a level incompatible with health and within an ace of fatal disaster. Its power for harm is good evidence of its specific efficiency. In one hospital ward a man of 62 who received 10 units of insulin at 1 P.M., followed by his usual dinner at 2.30 P.M., awoke from a snooze at 3.30 P.M. in a feeling of apprehension with staring eyes, thick speech, rapid and feeble pulse, to become unconscious and incontinent at 5 P.M., with a blood-sugar level of 0.09 per cent. Fortunately an intravenous injection of glucose in normal saline solution, followed by glucose and lime-juice by the mouth, restored his working level of glucose in the blood. Evidently insulin should never be given during periods of abstinence from food, as even the accidental omission of a meal expected to follow a dose may lead to harm. Nor is it glucose alone on which the remedy is able to act, for it appears that the accumulation of ketones and other disorderly metabolic products in the blood has been similarly reduced. One of the most important and puzzling facts so far disclosed is the difference in reaction to insulin of the true diabetic coma and the post-operative coma which may arise in diabetics. Clinical investigation shows some primary difference between these and has opened up a field for further investigation. The importance has been demonstrated of getting a diabetic into the best possible condition before attempting operation. No doubt the first thought in the minds of many will be whether even yet anything has been obtained in the way of a cure for diabetes as distinct from a welcome alleviation of one or more of its most troublesome symptoms. The report of the Medical Research Council is quite definite on this point. As yet there is no satisfactory evidence—time has hardly allowed of that—to show that diabetes in its most serious forms can be completely cured by insulin. Under insulin treatment tolerance may and does alter in the direction of improvement; it does not necessarily do so; it has even changed for the worse. In a man, for three years on starvation diet, who had dropped from 14 to 6 st. in weight, a small dosage of insulin made him at first sugar free; when the diet was made more generous the dose of insulin had to be quadrupled in order to keep the urine free from sugar. But whatever the details that remain to be worked out, there is no doubt that the clinician has at long last come into the heritage of LANGERHANS and LAGUESSE.

Annotations.

"Ne quid nimis."

THE BOWMAN LECTURE.

THE Bowman lecture to the Annual Congress of the Ophthalmological Society was delivered by Dr. George de Schweinitz, President of the American Medical Association, who took as his subject *Certain Ocular Aspects of Pituitary Body Disorders, mainly Exclusive of the Visual Central and Peripheral Hemipic Field Defects*. After paying a tribute to the memory of Sir William Bowman, the lecturer detailed the results of his researches, in conjunction with Dr. J. Parsons Schaeffer, professor of anatomy in the Jefferson Medical College, Philadelphia, into the anatomy of the pituitary region. In 125 bodies examined it was found that the optic chiasma was in direct relation to the chiasmatic sulcus in only 5 (or 4 per cent.), although this was the position universally assigned to it in anatomical text-books. The relationship of the chiasma to the diaphragma of the hypophysis was also variable; in 96 per cent. the chiasma lay wholly or partly over the diaphragma; rarely it lay completely behind the diaphragma upon the dorsum sellæ. Thus, while in the majority of cases the pressure of a tumour of the pituitary body of sufficient size would tend to fall upon the cross fibres of the chiasma, in those cases where the chiasma lay upon the dorsum sellæ the tumour would tend to separate the optic nerves without in any way stretching the cross fibres of the chiasma. The space between the diaphragma and the hypophysis varied from a potential cleft up to 10 mm. and was dependent upon the degree of development of the brain stem and the level of the tentorium cerebelli. Further, the diaphragma itself showed considerable variations; it might be stout, or frail and fenestrated. Considerable enlargement of the pituitary body might therefore exist before any pressure effect could be exerted upon the chiasma. The vessels of the circle of Willis also were very variable. While the visual arrangement brought the anterior cerebral arteries into relationship with the optic nerves in front of the chiasma, there were cases in which one or both vessels crossed the chiasma or even the optic tracts. Again, the posterior communicating arteries had an occasional and varying relationship to the optic tracts. These variations were sufficiently common to make it possible that vascular constriction might upon occasion play an important part in the production of field defects in cases of pituitary tumour.

As the result of his anatomical observations the lecturer concluded that there was a difficulty in accepting pressure or traction (or both) upon the optic chiasma in cases of pituitary tumour as the sole cause of the field changes. The scotomata which could not be explained upon the pressure or traction theory might, he suggested, be due to a toxic effect; toxins from the tumour might conceivably attack first the more highly specialised macular fibres. The possible anatomical pathway by which the toxins might reach these fibres was discussed at considerable length. In support of this theory Dr. de Schweinitz pointed out that the physiological pituitary enlargement of pregnancy which frequently produced an appreciable degree of hemianopsia never gave rise to a scotoma; in these cases it was supposed that there was no toxin from the pituitary. After discussing the progress of the hemianopsia of pituitary enlargement, the lecturer pointed out how these manifestations might be confused with those due to toxic amblyopia, sphenoiditis, or tabes dorsalis; the differential diagnosis was to be made by careful perimetric observations by modern methods, since each disease had its distinguishing features. Tabes dorsalis was, however, not infrequently associated with pituitary derangement; indeed, it had been

suggested that Charcot's arthropathy was a result of hypophyseal change. After double oophorectomy the lecturer had observed similar visual changes to those of pregnancy, but in this case the changes were permanent. The assertion that in methyl alcohol blindness, which at the present time was attracting considerable attention in America, the primary lesion was in the pituitary body was disproved by the lecturer's experiments upon dogs. The comparative frequency of tuberculous lesions of the pituitary body was also referred to and the possibility of a causal relationship between these and tuberculous affections of the eye. Earlier diagnosis of pituitary tumour might be hoped for when the significance of the "pituitary types" of headache (which often existed for years before any other change was apparent), and of the earliest appearance of amblyopia was more generally recognised. A further aid to diagnosis was the peculiar pallor of the optic disc very characteristic of pituitary disorder. As regards the adjuncts to the surgical treatment of pituitary tumour, radiation by X rays or radium helped to prevent recurrence and was beneficial where the return of visual changes showed that recurrence had taken place. Medicinal treatment by a combination of mercury and pituitary extract was also helpful; mercury seemed to be a powerful adjunct to pituitary extract even when there was no possibility of a syphilitic element in the case. In conclusion, the lecturer pointed out that the X rays might be most fallacious as a means of diagnosis, since very extensive enlargement of the pituitary might exist without any demonstrable change in the sella turcica.

SICKNESS AND OCCUPATION.

SICKNESS has become since the establishment of National Health Insurance a direct economic issue for the community; it has always been an economic issue for the person afflicted. Yet our only measure to-day of the health of the community, or of its constituent parts, continues to be mortality-rates. There is no useful information available concerning sickness-rates distributed by causation and age. Nevertheless the fact attracted attention long ago that influences conducive to morbidity are not identical with those which concern mortality. Thus, Finlaison in 1854 wrote that "locality, although exercising a certain virtue perhaps on the position of an individual attacked with sickness, had not very much to do with the average amount of demand which was likely to be made on the funds of a friendly society. . . . The only practical difference in the distribution of sickness that could be discovered was seen to turn on the amount of physical force called out by the occupation of the contributors." Neison in 1857 and Watson in 1903 followed up the point, and found little positive correlation between morbidity and mortality rates; in fact, the two indices might be negatively correlated. Watson further observed that geographical variations in mortality were greater than occupational variations, but that the reverse held good for sickness.

Clearly, then, if the outgoings for National Health Insurance are to be curtailed by lessening sickness, knowledge is needed of its prevalence and type in occupations. Once this has been acquired, efforts at prevention can be directed with some chance of success. The possibilities are great, as studies which are now being made in the United States indicate. The Public Health Service there, through the co-operation of a number of manufacturing companies and sick-benefit associations of employees, collect information as to invalidity experienced and its diagnosed causes. From time to time summaries are published in the Public Health Reports; they are of great value, even though they possess one marked drawback in not being distributed according to the age of those employed. This matter of age distribution is as important for sickness-rates as for mortality; thus, Finlaison formulated a law that "the sickness undergone during the first 25 years of working life

is the exact moiety of that distributed over the second 25 years." If, however, we assume, although the assumption is no small one, that the age distribution of those employed in the various reporting establishments is roughly the same, then comparisons can be instituted. When this is done such differences are found as 348 cases of sickness per 1000 persons per year in one establishment and only 48 cases in another. These are the extremes stated in the last report issued.¹

The information shows how sickness varies with season, particularly for all complaints which concern the respiratory organs; here the limits of variation are from 25 cases per 1000 in February to 6.7 cases in July. Bronchial affections stand out easily as first, so long as no epidemic of influenza is prevalent. Diseases of the digestive, circulatory, and nervous systems show much less variation according to season. Certain great causes of mortality, such for instance as tuberculosis, are found to play quite a subsidiary part in causing sickness. The difference found in the frequency of disease at different industrial concerns is striking. The standard attained at one concern should be possible at another; and knowledge that such standards have been attained should be stimulating to a health rivalry. The data as presented certainly indicate that great opportunities exist for reducing disability rates in industry. The present studies cannot be looked upon as more than breaking the ground of a new and untouched science. It is one, however, that for economic reasons we need to cultivate in this country, where, as in America, "before the problem can be intelligently attacked, we must ascertain in as much detail as possible, the causes of the widely different sickness-rates of certain industrial establishments"—and, we would add, of different occupations.

OPERATIONS FOR EXOPHTHALMIC GOITRE.

It is still frequently urged that the surgical treatment of exophthalmic goitre involves too high a risk to the patient. In the past, when the subjects on this disease were only handed over to the surgeon in the later stages, when the dangers in the use of chloroform were not recognised, and when the gland was more roughly handled and hæmorrhage was allowed to be more free, this may have been true. Little by little the mortality has been reduced, and in this country the published figures of James Berry, A. J. Walton, W. H. C. Romanis, and others have shown that if care be exercised the risk is but little greater than that of major operations. Dr. J. de J. Pemberton has now published the collected figures of the Mayo Institute in the *Journal of Surgery, Gynecology, and Obstetrics*. His paper is of considerable value in that it so clearly shows what are the possible causes of death and what are the best methods of avoiding them. In the year 1922 1093 cases of exophthalmic goitre were operated upon at this Institute. Stress is laid upon the fact that these cases were all true examples of exophthalmic goitre, a very necessary reminder, for the opponents of this form of treatment invariably claim that the good results are due to the inclusion of cases of simple goitre which may be operated upon without risk. For a case to be regarded as a true exophthalmic goitre it is necessary that the clinical findings, the basal metabolic rate, and the pathological investigation are all positive. Including such cases only in this group, Pemberton found that in the 1093 cases there was a mortality of only 1 per cent. It is well realised that in the earlier stages of the disease the risk of operation is much less, and it is probably largely because such cases are now coming to surgical treatment earlier in their course that such admirable results are obtained. Although the total mortality is so low, there are many possible causes of death. Any operation is not only likely to lead to an acute exacerbation of the hyper-

thyroidism, but if the disease has been of long existence the profound toxæmia may have caused secondary changes in the other viscera such as the heart, liver, and kidneys. The possibility of an acute hyperthyroidism may be diminished by careful preliminary treatment. At the Mayo Clinic it was found that 30-40 per cent. were in sufficiently good condition for early operation, 30 per cent. or so required 10-14 days medical treatment, and the remainder required some preliminary operation, such as ligation of the vessels. This preparatory treatment is of extreme value in lessening the danger when other visceral changes are present.

It has been long noted by many observers that if during the course of the operation the hæmorrhage is severe, the outlook is likely to be serious, but there is still some doubt as to whether these cases stand hæmorrhage badly or whether they bleed more because they are more serious cases and hence stand operation poorly. There can be no question, however, that every precaution must be taken to prevent loss of blood. For this reason every step of the operation must be slowly and methodically carried out, and every vessel should be tied before it is cut. By exercising care in the preliminary treatment, by careful choice of the time of operation and attention to detail in the operative technique, much may be done to lessen the other accidental complications. Special stress is laid upon the importance of operating before advanced changes have occurred in the other viscera, for it is the presence of such changes which so greatly increases the danger, a point to be remembered by those favouring the more conservative methods of treatment. Above all, it is clearly shown that in these cases, as indeed in all branches of surgery, correct diagnosis, skilled preliminary treatment, a careful selection of time of operation, and a knowledge of the after-dangers are as essential as technical skill in operating, points which need to be emphasised in these days when surgery is widely practised outside the teaching schools.

COMPLEMENT FIXATION IN TYPHOID DIAGNOSIS.

It has been felt for some time in Pretoria that the laboratory diagnosis of typhoid fever by the Widal test was far from satisfactory, and the annual reports of the South African Institute for Medical Research at Johannesburg have commented on the large number of cases of fever which are on clinical grounds clear and unambiguous typhoid in which the agglutination test has proved negative. The question is reviewed at length by Dr. Adrianus Pijper¹ in the light of an abundant and very careful personal experience. Using strains of bacilli from Europe as well as from local sources and the "standard" bacillary suspensions and sera issued from Oxford and Utrecht, he has made a special study of 120 cases which on general clinical grounds were regarded as undoubted typhoid; in 66, attempts at blood culture were made which were successful in 61. Of 199 blood specimens taken altogether, 20 per cent. gave no agglutination at all; of 73 patients who were tested more than once, 10 persistently failed to give any positive result. Taking a limit of agglutination at 1 in 40 as a "positive Widal," only 62 per cent. of the samples were positive. The readiest explanations which will be given for such results are that the patients had not, in fact, got typhoid fever or that the technique was in error. Dr. Pijper has been unable to find any case of paratyphoid infection in Pretoria and he is alive to the possibility of the presence of Malta fever, which he has on rare occasions identified. Errors of diagnosis can, however, be best disposed of by restricting our consideration to those cases in which verified typhoid bacilli were isolated from the blood. From 61 such cases 117 blood samples were examined, of which 44 gave a "negative Widal." The technique seems to have been thoroughly checked and the obvious possibility that there was

¹ Morbidity Among a Group of Wage-Earners. Public Health Reports, vol. xxxvii., No. 52. December, 1922. Washington Government Printing Office.

¹ South African Medical Record, 1923, vol. xxi., pp. 51 and 74.

something exceptional about the strain of bacillus used for the tests can be completely excluded owing to the great variety of cultures from different sources which Dr. Pijper tried. He also shows that culturally and serologically the infecting bacillus in Pretoria is identical with the European typhoid bacillus. From his results the author draws the natural conclusion that for purposes of rapid helpful diagnosis in the early stages of the disease the Widal test is not quite as good as some people have thought. His contribution is, however, something more than the old plaint that laboratory methods of diagnosis are not infallible, for, having put his penny in the slot with unsatisfactory results, he has devised another machine which works more certainly. Using a simple saline suspension of bacteria as "antigen," he got 96 per cent. positive results by complement fixation in the same series of sera which gave only 62 per cent. "positive Widal" tests; of the 120 patients one alone was never positive and no positive result was obtained in 60 controls. The method is more likely than agglutination to give a positive result in the early stages of the disease and the significance of a negative is so much the greater. In persons who have been inoculated, complement fixation generally soon becomes negative, although agglutination persists, which gives the former method a further point of advantage. It is of a good deal of general interest to note that the two reactions do not run parallel, and while the author has made out a strong case for his conclusion that "Widal's reaction ought to be replaced by specific complement-fixation tests," it is to be hoped that for a time, at any rate, the two methods may be tried together and their differences and similarities more closely studied.

THE MEASUREMENT OF VITAL CAPACITY.

SOMETHING over 70 years ago Dr. John Hutchinson published a little monograph on the spirometer after working for many years on the quantity of gases used in respiration and making thousands of observations. His discovery of the value of spirometry was not a mere fluke, for he was a close student of the coal-mines of his native Northumberland, and it was his knowledge of coal-gases which led him to adapt the principle of the gasometer to measure the respiratory disability. Later, as assistant physician to the Brompton Hospital, he urged the general use of the spirometer for the detection of early or threatened phthisis. Prof. G. Dreyer, of Oxford,¹ recently brought these observations of Hutchinson to the light of day and himself continued the investigation into the normal vital capacity of man, bringing it into relation with the size of the body. Prof. Dreyer correlated vital capacity with other physical measurements, with a view to obtaining a working guide to physical fitness under different conditions and in different classes of individuals. Formulæ were evolved to define the relationships between vital capacity, body surface, body weight, trunk length, and chest circumference. In association with Dr. L. S. T. Burrell,² it was demonstrated that in pulmonary tuberculosis there was a definite decrease in vital capacity from the normal for the individual of that occupation and mode of life. Improvement in the clinical condition was found to be accompanied by an increased vital capacity which might be used to measure the benefit received from treatment. Several papers have appeared since, confirming the value of vital capacity estimation in diagnosis, prognosis, and treatment. The mathematics of the subject has now been made the object of an elaborate study by biometricians, one of whom, Miss E. C. C. Allen, died during the course of the work. In *Biometrika* for March Lucy D. Cripps, Major Greenwood, and Ethel M. Newbold give the results of this study of the inter-relations of vital capacity, stature, stem length, and weight, in a sample of healthy male adults. The monograph confines itself to the

simple biometric question, with what success can vital capacity be expressed as a function of other bodily measurement such as stature and body weight. The conclusion is drawn that the relation between vital capacity and these other factors is rather better described by multiple linear regression formulæ than by the rational formulæ of Dreyer. The variability of the vital capacity of normal male adults is very great and it remains very great—being reduced by less than 25 per cent. of its initial value—when as many as four independent variables are used for estimation. It does not appear that either biometric or rational formulæ can deduce from anthropometric constants estimates of normal vital capacity within sufficiently narrow limits to possess real prognostic value in individual cases. Hutchinson's method therefore remains as good as or better than its recent modifications.

FRACTURE-DISLOCATIONS OF THE HIP-JOINT.

IN the *Journal of the American Medical Association* for March 17th Dr. Guy Hinsdale reports a case of a fracture-dislocation of the hip in a woman of 55 years, weighing between 11 and 12 stones, who fell in landing from a motor launch in such a way that the whole force of the fall was brought to bear on the region of the left hip. Attempts at reduction under general anaesthesia failed, though the head of the femur could be manipulated opposite the acetabulum. During these manoeuvres crepitus could be distinctly felt. An X ray photograph showed a fracture of the head of the femur, the fragment lying on the lower margin of the acetabulum, there being a posterior dislocation on to the dorsum ili in addition. The fragment, removed by exposure of the joint, was found to comprise about one-third of the head, including the attachment of the ligamentum teres. The subsequent convalescence was uneventful, and a perfectly useful limb resulted. As Dr. Hinsdale points out, fractures of the femoral head are not common, while fracture-dislocations are very rare. If the anatomy and function of the hip- and shoulder-joints be contrasted, it will be readily understood why this lesion is so rare in the one and so common in the other. A search through the literature of the past ten years reveals only one case of a fracture-dislocation of the hip, described by W. C. Campbell last year in the same journal. Dr. Campbell's case was exactly comparable to the subcoracoid dislocation of the humerus with avulsion of the great tuberosity, in that there was a perineal dislocation of the femur with a fracture of the trochanter. Dr. Hinsdale's case is possibly unique, and points a useful moral of the ever-present necessity of taking an X ray photograph in all cases of suspected fracture. It is conceivable that in this case, if a reduction had been easily effected, a photograph might have been omitted, when a painful joint would have resulted with limitation of movement due to the fracture.

LES PETITS PSYCHOPATHES.

Dr. Petre Trisca has been commissioned by the Roumanian Government to gather information as to the methods of dealing with mental disease now employed in France, and has published in book form¹ a preliminary report on the results of his inquiries. The earlier part is historical. He sketches the appalling condition of the insane before their humane treatment was introduced in France by Pinel, and carries on the narrative by outlining the careers of Pinel, Esquirol, Ferrus, Voisin, and Guislain, indicating the part played by each in reforming the treatment of the insane. For information as to present conditions Dr. Trisca is indebted to the officers of the "Comité d'Hygiène mentale" and the "Ligue de Prophylaxie et d'Hygiène mentales." These organisations, which embody the progressive element in French psychiatry, were founded in 1920 and 1918 respectively, the

¹ THE LANCET, 1919, ii., 227.

² Ibid., 1920, i., 1212.

¹ La Prophylaxie Mentale. By Dr. Petre Trisca. Paris: A. Maloine et Fils. Pp. 214. Fr. 20.

former being a governmental committee with corresponding powers, and the latter a society of private individuals with an extensive membership, exerting its influence chiefly by means of propaganda. At the psychiatric clinics in France treatment is provided for sufferers from minor forms of mental disorder ("les petits psychopathes," as they are called in France; a corresponding English term does not exist, and is much needed), and Dr. Trisca gives an account of the work of corresponding clinics in Switzerland and Germany. Much attention is devoted by him to the social service system of America, whereby the home conditions of the patient are observed and to some extent controlled. He is impressed by the necessity of smoothing the path of the patient discharged as cured from an asylum by educating his relatives to receive him in the right way, by finding him work, and, if necessary, by maintaining his treatment. This work, which is carried out in England by the Mental After-Care Association, depends to a great extent for its success on the re-education of the public in matters of insanity, a wider issue to which less prominence is given in the programmes of these French organisations than it would appear to merit. Another important variety of the work in view is the classification of industrial and other workers according to their mental capacity. Not only can industry benefit by the mental suitability of each employee for the work he is doing, but the employee is spared the danger of ill-health, either physical or mental, due to excessive fatigue produced by work for which his powers are unsuited. The lengths to which this project has been carried in America and Germany are known, and the results of applying the Binet-Simon tests to recruits in the American Army have been the subject of comment in our own press. More adequate provision might well be made in France for the education of the mentally defective. A law enabling local authorities to found schools for this purpose was passed in 1909, but very few such schools have come into existence.

The most pressing need of all is provision for the potential insane, the uncertifiable people of small means suffering from hysteria, phobias, and compulsions, depression, hypochondria, anxiety states, and drug habits. Dr. Trisca describes a number of such cases in an appendix to his book; the melancholy conclusion to be drawn from almost every one is that nothing effective could be done unless the patient could be taken into an institution, whereas very few beds are yet available for illness of this kind. Dr. Trisca has apparently not visited England, nor does he refer to any work in this direction now being done in this country. He has, however, collected sufficient data in France to provide his own Government at Bucharest with work for some time to come, and one can only hope that the political situation there, which hardly seems favourable at the moment for changes of this kind, may improve sufficiently to enable him to use his experience in the achievement of some practical reforms.

A VISION OF PREVENTIVE MEDICINE.

Dr. John Dill Robertson, formerly health commissioner of Chicago, has lately published a paper with the provocative title *The Health Officer's Challenge to the General Practitioner*.¹ There is a provocative spirit in the body of his paper as well as in its title, and this spirit is intentional for, as Dr. Robertson says, "I hope the message may irritate him (the general practitioner) sufficiently to stimulate him to assume his proper duties—it seems there is not much stimulation without irritation." Two quotations may show what Dr. Robertson means by stimulating by irritation. "I charge the general practitioner with negligence—aye, with criminal negligence of his own families. . . . I do it in the hope that somehow, some way, he may get the message, and that he may heed it in time to forestall

State medicine." Another passage runs: "We find the general practitioner, in many of our cities, obstructing, finding fault, with modern progressive ideas for health conservation; and this is not confined alone to the neighbourhood physician, but to many of our so-called leaders in the medical profession." So much for stimulation by irritation. Having harrowed his soil, Dr. Robertson proceeds to fertilise it with constructive ideas. He points out that in Chicago there are about 600 individuals to each physician. If each physician were to assume responsibility for keeping each of these 600 well by carrying out annual physical examinations, by vaccinating them against small-pox and typhoid fever, by encouraging the use of pasteurised milk, and by keeping children away from open cases of tuberculosis, then ". . . there would be but few sick out of their 600. . . ." Dr. Robertson's advice is detailed as well as general. To the potential convert to preventive medicine he says: "Go to your office to-morrow morning, take down your record and find how many people there are for whom you are the family physician. Take those that have been to your office during the past year; write them a letter; tell them you would like to have them drop into your office, that you would like to talk to them . . . and sell them the idea of health. . . . Tell them that they should have a thorough physical examination . . . and when you make this examination, make an examination that will impress them, not a careless one, not a stick-out-your-tongue-let-me-feel-your-pulse examination, but an examination that they will talk about . . . an examination from head to foot . . . ; and when you get all through with your instructions and with your examination, then you are ready to have them sign up with you for a continual, continuous audit of their physical banking account." Dr. Robertson knows how to temper idealism with lucrative realism, for he adds: "and when you have 600 patients signed up you will be amazed at the fact that your income has doubled and trebled in the course of a year."

IDIOSYNCRASIES OF BLOOD-VESSELS.

THE classic study of the phenomena of the circulation has depended chiefly on the transparency of the tissues in such membranes as the web of the frog's foot, its lungs, mesentery, retro-lingual membrane, and thin muscles, and in more or less transparent tissues in mammals. A method for observing the circulation of the blood in the cutaneous capillaries of man by means of a powerful beam of light falling on the surface of the skin was devised by E. Weiss, and this method has been used successfully in the medical clinic of Tübingen. Ernst Wertheimer of the Physiological Laboratory, University of Halle, has employed a similar method whereby it is possible, by directing the light from a powerful Nernst lamp, to study the intact circulation in the organs of curarised or narcotised frogs.¹

In the case of living *muscle* in situ, the most convenient muscles were found to be those on the flexor side of the arm or leg. The brilliantly illuminated surface of the muscle or other organ is first irrigated several times with Ringer's fluid at room temperature and then the fluid containing the substance to be investigated is similarly applied to the vascular part of the organ. Minute quantities of lactic or phosphoric acid (1/2000 to 1/10,000) cause the smallest blood-vessels of striped muscle to dilate gradually and accelerate the circulation. Too strong concentrations of these acids at first cause narrowing and often dilatation of the vessels. Other acids, acetic and hydrochloric acids, did not give such definite results. It would seem that metabolites of muscular activity such as lactic and phosphoric acids, influence favourably the circulation in muscle. Na_2CO_3 (1/1000) constricts the vessels, may cause capillaries to disappear, and arrests the circulation. Adrenalin (1/10,000 to 1/40,000) has a definite

¹ Bulletin City of Chicago Municipal Tuberculosis Sanitarium, March, 1923.

¹ Pfüger's Arch. f. d. gesam. Physiol., vol. cxvii., 1922.

slow vaso-constrictor effect, the capillaries become narrower, and the circulation at length ceases; but the action of adrenalin on muscle vessels is by no means so prompt as on the intestinal vessels. Choline and pilocarpine showed no action. The moderately inflated lung is admirably adapted for the study of drugs on its blood-vessels. In contrast to the blood-vessels of most other organs, its vessels are largely indifferent to drugs that affect vascular tissues of other organs. Adrenalin in the above-mentioned concentration is without effect, but a supersaturated solution of CO₂ accelerates the circulation in the lungs, while weak alkaline solutions produce the opposite effect. Choline, which is formed in the intestinal canal, has a specific action on the circulation in the *intestinal wall*, which it dilates and accelerates. Pilocarpine has a similar action. Atropine (1/1000) does not appear to act on the normal intestinal circulation, but when the blood-vessels are dilated by choline atropine causes constriction. Ca and Mg accelerate the flow, while K narrows the vessels; but in any case a certain relation between the potassium and calcium salts is necessary, for if the former are in excess, the choline action does not occur, if the latter is in excess, the result is the reverse. The choline action is also reversed by the previous application of preparations of thyroid and pituitary gland. Adrenalin acts definitely on the circulation of the intestine, liver, and spleen, it constricts the blood-vessels of the kidney and dilates those of the suprarenal body.

The author concludes that each organ is provided with blood-vessels peculiar to itself, and that the blood-vessels of one area react differently from those of another vascular area. Substances resulting from the metabolism of different organs, and in part excreted by them, are of great importance for the condition of the blood-vessels of the corresponding organs and for the increased circulation of the blood during increased functional activity—e.g., lactic and phosphoric acid in muscle, choline in the intestine, adrenalin in the suprarenal, and CO₂ in the lungs.

THE PROGNOSIS AND TREATMENT OF SPONTANEOUS PNEUMOTHORAX.

In the *Schweizerische medizinische Wochenschrift* for March 22nd there is a paper by the late Dr. Lucius Spengler, who had a long and varied experience of spontaneous pneumothorax in the subjects of pulmonary tuberculosis. It is curious how remarkably the results achieved by various physicians differ. Some regard a spontaneous pneumothorax, occurring in the course of pulmonary tuberculosis, as an almost invariably fatal complication. Drasche's statistics would seem to justify this pessimism, for there was only one recovery among 189 cases. West's results were only a little better; there were 11 recoveries among 167 cases. Dr. Spengler, in the course of 30 years, treated 42 cases of spontaneous tuberculous pneumothorax, and in as many as 16, or 38 per cent., the patients recovered from the pneumothorax. In seven of these cases the patients also recovered completely from the pulmonary tuberculosis, this recovery being maintained for several years. Only in four cases did the patients die within a week of the accident, but there were as many as 15 who died between the second week and the second year. In almost every case the pulmonary disease was progressive at the time of the accident, and it is noteworthy that the average age of the 16 patients who recovered from the pneumothorax was only 24 years. In 11 of these 16 cases the disease was unilateral, and in none of them did a purulent "malignant" pleural effusion occur. These facts explain in part the comparatively high proportion of successes achieved by Dr. Spengler. But they do not explain them entirely, and it is probable that many of the patients owed their lives to the patient skill with which Dr. Spengler attended them. One of his guiding principles was to encourage every condition likely to favour permanent closure of the rift in the lung and visceral pleura. Realising that a large effusion may provide much fibrin where-

with to plaster the pleura and close this rift, he was careful not to aspirate wholesale, and when artificial pneumothorax treatment was introduced he adopted the principle of partial gas replacement. He found that when the pneumothorax remained dry, the rift in the lung was apt to keep open, and to close it he advocated the introduction of some pleural irritant with a view to provoking a small effusion which would plaster the lung with fibrin. In one such case he introduced 30 c.cm. of a 30 per cent. solution of grape-sugar in normal saline, and the small effusion which formed proved most beneficial. Another reason for Dr. Spengler's high proportion of successes may have been his inclusion of cases which, in less skilled hands, might have escaped diagnosis. Recent work in America has shown that many cases of spontaneous pneumothorax give rise to such slight symptoms that, but for the help of the X rays and careful clinical examination, they would escape notice. Indeed, it is probable that most cases of spontaneous pneumothorax in consumptives are not diagnosed as such.

THE CANCER PROBLEM.

WE have just received the annual report of the Cancer Commission of Harvard University for the year 1921-22. This volume of 70 pages contains little that is of interest to the clinician and has no reference to any work having been carried out dealing with the central problems of cancer. At one time the Collis P. Huntington Fund, which is under the control of the Cancer Commission of Harvard University, was one of the centres of the scientific investigation of cancer by experimental methods. Some years ago the Committee decided to drop this line of cancer research and to devote all its resources to the clinical treatment of cancer and to the development of radiotherapy. It is a matter of regret that the oldest university in the States should in this field have abandoned its high academic traditions as a consequence of the loss of faith of its Cancer Committee in scientific investigation. To many it will seem that courage has failed the workers at a most unfortunate moment. We had occasion recently in reviewing the first volume of the *Proceedings* of the Leeuwenhoek Vereeniging to draw attention to the important advances which have been made during the last few years in our knowledge of cancer. The work of Fibiger in Copenhagen and of Yamagiwa and Ishikawa in Japan has opened up a new line of research which has been and is being actively pursued all over the world in such leading cancer research laboratories as the Crocker Cancer Research Fund in New York, the Imperial Cancer Research Fund in London, the Cancer Hospital in London, and the Antoni van Leeuwenhoek Huis in Amsterdam. We hope that the great University of Harvard will take heart again.

THE third annual report, issued to-day,¹ of the Industrial Fatigue Research Board records an important stage in the history of the work. Up to the present the staff of investigators have been feeling their way through the many opportunities existing in the industrial field, but the time is now arriving when as the combined result of their investigations principles of general application begin to appear. Four independent inquiries have shown the advantage alike to manufacture and to personnel of avoiding excessive moisture in cotton-weaving sheds; two recent reports confirm the increased productive efficiency as a result of better lighting in weaving; from different sources the curve of output and the curve of accident have been shown to correspond fairly closely. The Board proposes to continue the study of fatigue and efficiency on general lines, regarding no study as complete until definite numerical values can be attached to it. Satisfaction is expressed at the growing interest shown by manufacturers in the work of the Board and at the growing usefulness of the recently formed National Institute of Industrial Psychology.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

XVIII.

HEART FAILURE: PREVENTIVE TREATMENT.¹

Prophylaxis.—The two great single causes of heart disease are acute rheumatism and syphilis. The removal of enlarged tonsils in children lessens the risk of rheumatic infection. Salicylate should not only be given in adequate doses during the acute stage of rheumatism, but continued in smaller doses—e.g., gr. x., t.d.s.—for many weeks without intermission as a routine in a restful convalescence; iron and cod-liver oil should be the accessories. Similarly, thorough treatment of syphilis is likely to reduce the incidence of syphilitic aortitis which so often involves heart as well as aorta.

General Management.

When a patient is known to have heart disease, and failure is not yet in evidence, there are certain measures calculated to postpone or even prevent failure. It may be permissible to reiterate them, for some are forgotten in the hurry of practice. It is better that the underclothing should be thick than that the patient should carry about the load of a heavy overcoat, and for this a light fleecy one may be substituted. Thick socks or stockings are advisable and boots which are waterproof and big enough. As sleep is so important, in winter the air of the bedroom should be warmed as well as the bed itself, for it is often the change to the cold air of the bedroom which starts the nightly cough. Where failure is hardly avoided the bedroom may with advantage be on the ground floor. In the daily life of these potential invalids there is greater need of physical rest. An hour earlier to bed each night and a half day in bed on Sundays, or a whole day in bed once a week is a good rule. They should have a first call on the couch and choose it rather than a chair, for instance when they read in the evening. If it can possibly be arranged, they should remain indoors on wild and damp days so as to lessen the risks of catarrhal infection. If in spite of all precautions acute bronchitis, influenza, tonsillitis, or one of the infections of unknown origin reaches the patient, he should be longer in bed and have a longer convalescence than his robust fellows. A source of infection, such as enlarged tonsils or pyorrhoea, must be treated at any age not only because it may dispose to earlier failure, but also to eliminate sources of secondary infection which may increase the risk of infective endocarditis.

Diet.—There is no reason why the diet in chronic heart disease without failure should be much modified. A dry mixed diet will meet the ordinary needs in limiting the fluid intake, and in avoiding the flatulence which is the chief dyspeptic difficulty of these patients. They are tempted to take too much tea, and this should be restricted in amount, though it need not be inferior in strength any more than coffee, remembering the diuretic properties of these beverages. Many find that they are much better if they take meals of almost similar bulk during the day—breakfast, mid-day dinner, and tea approximating in amount. Hot milk or a hot milk preparation is very suitable alone as supper. If alcohol is taken it should be as light wine with meals, or weak spirits at night. It is unnecessary in most cases to interfere with moderate smoking habits; if dyspnoea is at all pronounced, this in itself will restrict the desire for it, but if pain of any severity or significance is present smoking almost always accentuates it and abstinence is well worth while.

¹ An article on the Therapeutics of Heart Failure will appear in the next issue of THE LANCET.

Exertion.—It is seldom such a difficulty as might be anticipated to decide when exertion is permissible in chronic heart disease. The cardinal symptom as a guide is breathlessness on exertion. This is Nature's brake where the heart is limited in power, and if the patient will learn to avoid exertion which evokes distress such exertion is not doing harm. We are not here dealing with acute infection of the heart where movement is limited on a principle (rest for repair) without regard to symptoms. Exercise within the limits imposed by the symptoms does no harm, but rather good in the patient with established heart disease free from complications. It improves the digestion, the muscular action aids the circulation, and the natural fatigue promotes sleep. Moreover, there is no better way to reassure the subject of cardiac disease than to permit reasonable exertion. He should make his own pace, noticing his greatest limitation at hills and in a high wind.

Employment.—A man so situated that he must work should strive to obtain a modified form of employment which entails less exertion than before, and if it is also one where regular attendance is not imperative it becomes almost ideal. Here is one of the advantages of home employment or trade where time off can be more easily obtained if premonitory symptoms of failure are noticed. Clerical or pay-box work in a small business, light bench work as a carpenter, sitting occupation in the jewellery and tobacco trades are some suitable forms of employment. One who has worked in a labour yard may become a checker or time-keeper. Tailoring is often suitable work, but heavy irons may have to be used. Basket-making is taught to some pensioners with heart disease. The employer should know that the men permitted to undertake such work are not likely to drop dead. Contrary to the lay view, patients with chronic heart disease usually take a long time to die. If we exclude acute infections of the heart, angina pectoris, syphilitic aortic incompetence or aneurysm, and arteriosclerosis with excessive pressure, we are left with the average case of rheumatic heart disease where the risk of sudden or unexpected death is remote. Incidentally, if this be true, it should be our pleasure to acquaint the patient with the fact and to act upon it.

The Prevention of Heart Failure in Acute Infections.

In many infections, as pneumonia, specific therapy is wanting and treatment centres round the heart and means for its support. By good nursing exertion is reduced to a minimum. Sleep is obtained and cough is relieved by morphine at night in the early stages. Later, if cyanosis appears, oxygen should be administered through the nose by a soft rubber catheter connected with the rubber tube instead of the wasteful funnel. If with cyanosis the veins are distended and circulatory embarrassment is obvious, a venesection to 10-20 ounces is indicated. Little reliance can be placed upon such popular drugs as caffeine, strychnine, and camphor if the heart is failing; pharmacological and clinical evidence of their efficacy is meagre. The same is true of brandy, though its narcotic or sedative action may be useful. There is more justification for the use of digitalis, for this drug can at least affect the heart, but there is no agreement as to whether it can or cannot ward off failure if given throughout an infection.

Postponement of Failure in Syphilitic Heart Disease.

The distinction between rheumatic and syphilitic aortic incompetence is more important than the distinction between aortic incompetence and mitral stenosis. A syphilitic history or a positive Wassermann reaction, in the absence of a rheumatic history, gives the key to a rational treatment for preventing heart failure. It is a tertiary lesion in a dangerous place. Hutchinson's pill (hyd. c. creta, pulv. ipecac. co., aa gr. i.) t.d.s., and a bitter mixture containing potassium iodide gr. x., also t.d.s., is convenient for

prolonged administration. In cases not progressive nor too advanced, after a month of such treatment the use of salvarsan should be considered. If decided upon, novarsenobillon intravenously, 0.3, 0.45, 0.6, 0.6, 0.6, 0.6 g. in successive weekly doses is suitable. By anti-syphilitic treatment we may postpone or prevent not only heart failure in its ordinary form, but the special dangers of angina pectoris and aneurysm.

Prevention of Heart Failure when Auricular Fibrillation is Established.

In every practice there will be some among the known subjects of heart disease, especially mitral stenosis, in whom the heart has become persistently irregular and rapid. Where the onset of fibrillation is recent, and in selected cases, quinidine may succeed in restoring the original regular rhythm, and to that extent may postpone failure. Where fibrillation occurs in paroxysms quinidine may also be useful, for it inhibits these attacks which are so often preliminary to established fibrillation.¹ In most cases, however, we have to accept the new phase in the life-history of the cardiac patient—he is the subject of auricular fibrillation, the pulse is permanently and completely irregular. Increased breathlessness on exertion, if nothing worse, tells of the nearness of heart failure. Rest makes surprisingly little difference either to the symptoms or to the character or rate of the pulse. Rest indeed does not meet the case, but digitalis usually meets it to such an extent as to render prolonged rest in bed superfluous. If any drug is indicated in any condition, digitalis is indicated here, and these patients have a right to a fair trial of it. In the average case it will be found that 10 minims of tincture of digitalis, B.P., three times a day, will reduce the breathlessness on exertion to a noticeable degree and restrain the pulse-rate to 60–80 a minute. To continue the right dose of digitalis indefinitely is the surest way to postpone failure indefinitely.

THE WORK OF THE PENSIONS MEDICAL SERVICE.

I. ENTITLEMENT TO PENSION.

OF all the issues left by the Great War none, perhaps, affects the public more nearly than that of pensions. The granting or withholding of pensions, their amount, the composition and conduct of medical boards, the payments of treatment and other supplementary allowances, the supply of artificial limbs, the care of insane ex-Service men—each in turn has agitated and still perturbs the public mind. The reports of our Parliamentary correspondent, published week by week in THE LANCET, show that the department responsible for the administration of war pensions discharges its duties under a constant running fire of criticism, often well-informed and helpful, but at times somewhat severe. To the medical profession, however, all these are matters of particular interest, and, if we were ourselves to join the critics it would be to say, first, that the extent to which practically every decision and act of the Pensions Department turns upon medical opinion has never been adequately and plainly set forth; and, secondly, that the general, and even the medical public, have never been fully informed of the great mass of medical work accomplished under the direction of the Ministry.

¹ THE LANCET, 1922, ii., 1267.

The Principle of Attributability.

Under the Royal Warrants the Minister of Pensions has power to grant pensions to officers and men in respect of injury or disease certified as attributable to or aggravated by military service during the war. So far as disablement pensions are concerned it is to be observed that the disability must be attributable to or aggravated by and not merely on service, and we believe that considerable misapprehension has arisen through failure to appreciate this distinction. The decision as to whether military service has, in fact, so caused or aggravated the disability is fundamental, for on this decision hangs not merely the right to pension, but to treatment at the cost of the State, to treatment allowances when in consequence of undergoing treatment the pensioner is prevented from following his remunerative employment; to other supplementary allowances for which the man may be eligible; to treatment combined with vocational training in a new occupation when this is recommended; and, it may be, to pension and allowances for the widows and dependents. This decision is based on medical opinion, the opinion of a medical board, or boards. Following this decision almost every action taken, the amount awarded, treatment and allowances, vocational training with treatment, and so on, turns on a medical point.

As in the great mass of cases the question of attributability or aggravation—or entitlement, as it has come to be named—has long since been settled on the basis of reports of the proceedings of medical boards of the Navy, Army, Air Force, Ministry of National Service and Ministry of Pensions, it may seem that now, with certain exceptions, this question is mainly of retrospective interest. Among these exceptions the principal are claims arising under Article 9 of the Royal Warrant where disablement reveals itself after discharge, and claims to widows' pension under Article 11. Surprising though it may be, claims on account of disablement due to military service are still, 18 months after the official termination of the war and more than four years after the actual cessation of hostilities, being preferred in large numbers for the first time. At present, excluding widows or dependents' cases, some 650 claims are made weekly, and fresh awards given at the average rate of 170 a week. Obviously, the greater the length of time which separates the claim and the military service of the claimant the greater the time and care required to come to a just decision. The whole of the official documents bearing on the claimant's medical history; extracts from hospitals in which he has been treated; the certificates of his pre-enlistment and post-discharge medical attendants, as well as those of his employers before and after the war, together with any other evidence the claimant may be able to produce, have to be anxiously considered in the light of the actual examination of the man, lest, on the one hand, injustice may be done by refusing the man his due, or, on the other hand, an injury may be done to all others properly pensioned, by conceding that to which the claimant is not entitled. In some cases the evidence of commanding officers and others, scattered in distant parts of the Empire, must be awaited, and bearing these facts in mind, the average time now taken in settling an Article 9 claim, between five and six weeks, is not unreasonable.

How the Principle is Determined.

At this point it may be well to refer to the machinery set up by the Ministry of Pensions in connexion with the determination of entitlement in its medical aspects. At the very beginning of this Ministry it became necessary to establish at headquarters, as part of the pensions medical services, a body of medical men, styled medical assessors, charged with the duty of examining the reports furnished by medical boards; of referring these reports back, where necessary, for further information, and generally of seeing that the medical grounds for decision were in accordance with the terms of the Royal Warrants.

In time, as a result of the wide experience gained, general directions for the guidance of medical boards were drawn up and issued to medical boards explaining the various Warrant provisions, at the same time emphasising the fact that the Ministry desired the unbiased, frank, and unfettered opinion of the examining doctors. These "general directions" have been considered section by section, have been amplified and amended by a Medical Disability Committee, specially appointed by the Minister, composed, as to the main committee, of the Presidents of the Royal College of Physicians and the Royal College of Surgeons, with eminent members of both Colleges, together with one or two representatives of the Ministry; and as to its numerous subcommittees, or main committee in special session, of consultants and specialists of the highest rank from all parts of the country. The Ministry, in fact, have wisely taken care to incorporate in these "directions" the authentic opinion of the medical profession of this country, as represented by its own acknowledged leaders. It seems equally certain that the views of the profession at large are reflected in the work of the medical boards of the Ministry. It is true that the numbers boarded weekly are only about one-half what they were two years ago, and that, in consequence, a smaller number of the general and specialist members of the profession are now occupied in this work. Thus, we understand that the number of officers and men boarded weekly at present is about 16,000 as compared with more than twice that number two years ago.

Medical Boards and their Staffs.

The numbers of medical men to-day employed by the Ministry of Pensions, either as whole-time salaried officials or employed part time on a sessional basis, may be taken as indicating the extent to which the medical profession at large share in the activities of the Ministry. We are informed that, not counting the 289 medical officials of the Ministry at headquarters and in the regions and the 226 whole-time salaried medical officers of Ministry hospitals and clinics, and disregarding 1600 medical referees, there are to-day over 4400 medical men serving on the medical boards and clinics of the Ministry, of whom 1269 are approved specialists—that is, that out of a total number of 6515 medical men engaged in the work of the Ministry, 515 are whole-time officers, and of these 289 are medical officials in the accepted usage of the term. It may be urged, however, that notwithstanding their sheer weight of numbers the decisions of medical boards and medical officers at hospitals or clinics may be over-riden by the comparatively small number of salaried medical officers. Here we are advised that a certain distinction has been necessarily drawn between an opinion on entitlement and one on assessment of degree of disablement, questions of a non-medical order, legal interpretations of the Warrants and ethical considerations as to misconduct and negligence entering into the former, whereas assessment of the degree of disablement is officially regarded as entirely for medical determination by the board examining the man. Certainly, however, entitlement to pension under the Warrant is mainly a medical question, and, therefore, it is reassuring to learn that, by Ministerial instruction, when a difference of medical opinion exists on a question of attributability or aggravation as between a board and a medical assessor or other official of the Ministry, the case must be referred to a medical board of reference for a decisive opinion on the medical aspect of the case.

Re-Survey and Appeal.

To the uninitiated the medical machine of boarding must seem somewhat elaborate. In addition to the ordinary medical boards examining men for the purposes of first awards and subsequent re-survey, there are medical appeal boards dealing with appeals against the amount awarded; neurological and other specialist boards; the medical boards of reference already mentioned; and special boards for the examina-

tion of men to whom the granting of final awards is under consideration. Each of the last four named boards contains an approved specialist as member to whose opinion the greatest weight is attached, and who, as a member of the outside medical public, cannot be accused of State bias. Almost invariably two, and frequently the whole three, members of these boards are medical men in general and specialist practice. As our readers are aware, the membership of the ordinary re-survey boards, which assess the degree of disablement, was reduced from three to two a year ago, and again almost invariably these boards are composed of members engaged in outside practice. It seems evident, therefore, that whatever charges may be brought against decisions on entitlement or assessment of disablement—and it is not to be denied that among the million and a half dealt with mistakes must have been made—the medical profession as a whole, both as regards the boards and the directions issued for their guidance, is directly concerned. The work—and we are here only considering entitlement and assessment—is responsible and often intricate; calls for exact clinical knowledge, judgment, wide knowledge of both medicine and men, and the constant exercise of tact and good-will to those who have served and suffered in the late war. There is every reason to believe that these requirements have been abundantly met. The medical boards have been well manned both as regards their ordinary and specialist members, the latter comprising consultants of high standing, whilst the consultant advisers of the Ministry at headquarters are all men of wide reputation and authority.

Quite naturally, considering the large numbers of men accepted for some form of service though already disabled to some extent on entry, doubts as to entitlement to State compensation must often have assailed the members of medical boards, but that, in accordance with Ministerial policy, the claimants have been generously accorded the benefit of doubt, and that each case is considered on its merits seems to be shown by the fact that whilst 1,500,000 disablement pensions have been awarded, only 300,000 claims have been rejected. There can, in fact, be no question that the provisions of the Royal Warrants on these medical aspects have been and are being fairly, indeed generously, interpreted and administered. This was, it will be remembered, the finding of an important departmental committee of inquiry two years ago.

CONTROL OF VENEREAL DISEASE.

REPRESSIVE MEASURES IN AMERICA.

THE forty-fifth annual report of the Department of Health of the State of New Jersey, 1922, a well-written document, which reflects much credit on Dr. J. C. Price, the director of the department, and his collaborators, will specially interest those who are working to control venereal disease. The estimated population of the State of New Jersey is 3½ millions, and from statistical tables in the report it appears that in the year 1921 compulsory enforcement of notification resulted in the reporting of 96 cases of chancroid, of 2738 cases of gonorrhoea, and of 3155 cases of syphilis. The number of cases for each of these diseases are not given separately for the two sexes; but of all three together 4541 male and 1448 female cases were notified. The death returns for these diseases are notoriously untrustworthy; but the statistical statement that the proportion between deaths and notified cases of venereal disease was 3 per cent. for the male and about 4·8 per cent. for the female cases appears to show that female are reported less completely than male cases. Whether so or not, it is highly improbable that the 5989 cases, which are less than 2 per 1000 of the population of the State, represent more than a fraction of the cases of venereal disease coming under the care of physicians in the State. In England and Wales the total number of new cases of venereal diseases coming under treat-

ment at the subsidised clinics in 1921 numbered about 1·6 per 1000 of population; a striking illustration of the virtue attaching to provision of facilities for treatment of patients as compared with compulsory notification with but a scanty provision of such facilities.

Demonstration Clinics in New Jersey.

The anti-venereal work in New Jersey has included the holding of demonstration clinics on the diagnosis and treatment of syphilis in ten cities in the State, which have been attended by over one-fifth of the medical practitioners in the State. Educational work has been done with three objects in view: to reduce the number of foci of infection, to reduce the opportunities for extra-marital sexual contacts, and to prevent sexual promiscuity. In preventing opportunities for promiscuous sexual intercourse stress has been laid on the education of special groups, with a view, for instance, to secure supervision of the juvenile delinquent who is likely to develop, if unaided, into the sexual prostitute, and with a view to repression of clandestine prostitution, the regulation of amusement places, &c. The prevention of sexual contacts outside the marriage state, it is appreciated, "resolves itself into the creating and crystallising of public opinion for the single standard of morality," and with this object in view carefully formulated educational work has been undertaken among key groups in every stratum of society. It is further recognised that the statement of biological, psychological, and sociological facts alone has relatively small influence in the building of character for individual chastity, this depending ultimately solely on a true education which includes character building.

The "Medical Case Worker."

Attention may be drawn to the efforts being made in New Jersey to fulfil the requirement of the State law to "investigate all cases that are under the care of reputable physicians and" to ascertain so far as is possible all sources of infection and exposures to the same." We wish further particulars had been given as to the practicability and extent of this work; so far it is evidently experimental in character. In one city a "medical case worker" has been appointed on the staff of the local board of health, and another for a group of municipalities. The medical case worker is expected to investigate the sources of infection of all known cases, both those treated in public clinics and those reported as delinquent by practising physicians; and is also expected to determine other foci of infection by the study of death and stillbirth records. There can be no doubt as to the value of this item. It is a class of work which, if it cannot be described as exactly neglected, is almost completely unexplored in the work of most sanitary authorities in England. Notification of stillbirths are received, and these only exceptionally are made the subject of inquiry, directed to ascertaining whether syphilis is concerned in the ante-natal death. It would be a valuable return if it could be ascertained by inquiry, for instance, in all the county boroughs of England and Wales, how many stillbirths were found in the year 1922 to be caused by syphilis. The inquiry would reveal how much anti-venereal work is waiting to be done: the inquiries in connexion with which would, it may be added, involve fewer delicate difficulties, than if cases of recent venereal disease in adults were to be the subject of domiciliary investigation.

Similar remarks apply to the large number of cases of interstitial keratitis and of other diseases indicating congenital syphilis which come under treatment in child-welfare centres, in the out-patient departments in children's and other hospitals, in work-house infirmaries, &c., in all of which most valuable familial anti-venereal work might be done with little risk of exciting friction or opposition, given tactful as well as zealous and intelligent workers.

"Suspected Contacts" in Illinois.

The new regulations promulgated by Dr. Isaac D. Rawlings, State Director of Public Health, are

distinctly severe, and are supported by a penalty of six months' imprisonment. "Any person known to be a common prostitute . . . or any man consorting with a common prostitute . . . or inmate of a house of ill-fame shall be deemed to be a suspected case of venereal or an infective carrier." If a person is known to have exposed himself or herself to infection, but is not found on examination to have venereal disease, he or she may be held by the health authorities as a "suspected contact" for the period of incubation of the suspected disease. If a suspected person refuses examination the refusal is considered evidence of infection, and the suspected person may be quarantined and his or her premises placarded exactly as though infection had been found. Doctors who have been in the habit of issuing certificates of freedom from venereal disease will continue this practice only at the risk of revocation of their licences. Druggists who sell preparations for the treatment of venereal disease must do so upon a doctor's prescription, or if no prescription is offered they must report the name and address of the purchaser to the health authorities. There is no doubt that a serious effort is on foot to deal with vice in the State, whose chief city has of late earned a distinctly unsavoury reputation in this respect. Whether some of these regulations by their very stringency may not defeat the object in view remains to be seen.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENT.)

THE KING INSTITUTE OF PREVENTIVE MEDICINE

THE report of the King Institute, Guindy, for the period from Jan. 1st, 1921, to March 31st, 1922, has just been issued, together with the Government review of its contents. The Director, Major J. Cunningham, I.M.S., in his introduction, describes the five main aspects of the Institute as follows: (1) A vaccine manufacturing depôt for the Madras Presidency; (2) a bacteriological laboratory for the manufacture of bacterial vaccines; (3) a laboratory for examination of clinical material for the Madras hospitals and the medical profession of the Presidency; (4) the Presidency public health laboratory; and (5) a research laboratory for the investigation of medical and public health problems. The Director points out that the various functions of the Institute are undertaken in most other provinces by two or more separate institutions. The Madras policy of concentration presents many advantages, especially as regards economy, whilst full opportunity is retained for expansion in every direction.

Vaccine Manufacture and Supply.

The decrease of 224,075 doses of vaccine lymph is undoubtedly due to the cessation of routine vaccination during the hot months, sanctioned by Government and brought into effect for the first time during the year under review. It is satisfactory to note that "a large proportion of those who were not vaccinated in the hot months presented themselves for vaccination during the cooler months." Major Cunningham estimates that cessation during the hot weather resulted in a net decrease of a little over 2000 vaccinations, but the expense and trouble of carrying out over 42,000 unsuccessful vaccinations have been saved. The stoppage has also been amply justified by the rise in the success rate from 66 to 75 per cent. The results obtained with 40·7 per cent. of the lymph issued are not known, and only a small proportion of this large number is due to revaccinations. It is not clear why all authorities and local bodies which receive supplies of lymph from the King Institute should not be compelled to furnish returns, so that the behaviour of the lymph can be gauged under all conditions. The merits of glycerine and lanoline lymph have been dealt with in a separate report on which the Government have already passed

orders.¹ By arrangement with the Director of Public Health and the President of the District Board, Chingleput, the Saidapet Range has been utilised by the King Institute for testing batches of lymph; this step has been of the greatest service, and there seems no reason why it should not be made permanent.

Monthly Success Rates.

The inferences drawn by the Director from the monthly success rates are: (1) That a stoppage of vaccination for two months is insufficient and that better results could be obtained by a four months' cessation throughout the Presidency, and (2) that the standard for successful vaccination adopted by the King Institute is higher than that generally accepted by the vaccination staff. Major Cunningham again emphasises the importance of taking into account the insertion success rate, and of the verification, as far as possible, of vaccination operations in the vesicle stage. Many cases are only verified after scar formation, and very small and doubtful scars are too often taken as evidence of success; these cases are in reality imperfectly protected or not protected at all, and when small-pox breaks out the disease may show a high incidence amongst the vaccinated. This fact disturbs public confidence in a well-proved measure of protection.

Bacterial Vaccines: Public Health.

The increasing demand for the anti-typhoid and anti-cholera vaccines is significant. Owing to the decline in the incidence of influenza, the number of doses of this vaccine dropped very considerably. In dealing with the public health section of the Institute, the Director draws attention to the ridiculously small number—61—of specimens sent for examination during the year. No standard of purity has yet been laid down for the common articles of diet in the Madras Presidency, although a "Food Adulteration Act" is on the Statute book, and it is understood that proposals for the appointment of a public analyst and the equipment of a laboratory are under the consideration of Government. Until these are provided the Food Adulteration Act will remain a dead letter.

Assistance to Other Departments: Education and Research.

A new feature of the report is a description of assistance rendered by the Institute to other departments. In this connexion Madras has again given the lead to other parts of India by the employment of bacteriological units sent out from the Institute for the investigation of special problems. The present report mentions the work done by such a unit in the Moplah Jail at Bellary, work which in a very short time effected a remarkable improvement in the health of the prisoners. Since then several other units have been sent out to different parts of the Presidency for the investigation of various epidemic outbreaks, and these have done extraordinarily good work. It is hoped that Government will encourage the system. The educational and research activities of the Institute are dealt with in the last pages of the report, and in conclusion the Director estimates the profits of the Institute as a whole at Rs.1,10,280, this estimate being based on the market value of the lymph, vaccines, and laboratory examinations made by the Institute staff.

The Prince of Wales's Hospital for Children, Madras.

It was decided that the great bulk of the money collected to celebrate the Prince of Wales's visit to Madras should be devoted to the erection of a children's hospital, with which Madras has been so far totally unprovided. A considerable sum of money was also collected after the armistice for the erection of a war memorial in the shape of a "Hall of Victory," but various difficulties have arisen to delay its completion. A medical school for women is to be

opened in Madras, and the present Victoria Caste and Gosha Hospital is to be replaced by a new hospital built alongside the new medical school. The Government have taken the opportunity to amalgamate the four buildings into one large group, to be built on vacant ground beside the Queen Mary's College for Women. The foundation-stones were laid on March 26th.

Madras, March 27th.

THE THIRTY-FIFTH CONGRESS OF INTERNAL MEDICINE AT VIENNA.

(Concluded from p. 868.)

THE third day was given up to a discussion on
Arterial Hypertension.

Prof. A. Durig (Vienna) and Prof. F. Volhard (Halle) introduced this subject. Prof. Durig dealt with the physiological aspect of the problem, pointing out that the pioneer researches were made in Vienna 80 years ago, when Ludwig, Basch, and Gärtner attacked the problem. The normal level of arterial tension was, he said, very variable, depending upon numerous physiological conditions such as muscular exertion, age, time of day, psychic state, and so on. It ranged between 90 mm. during sleep and 180 mm. Hg in the day; mere measurement of the blood pressure gave only values for comparison, not a definite test of hypertension. Hypertension was present if a disproportion existed between the quantity of blood expelled by the heart and the quantity of blood accommodated in the blood-vessels. Great importance was attached to the arterioles and capillaries in that respect, especially to changes in them, such as loss of elasticity or narrowing of lumen, either by thrombosis or arterio-sclerosis, when part of the cardiac force was spent without result. The significance of hypertension is not yet fixed; it may prove the existence of a fault in the heart or in the circulatory system. Exact analysis is needed. Hereditary influence and predisposition have been observed in 82 families with purely functional hypertension.

Prof. Volhard dealt with hypertension in connexion with kidney trouble and described two types of "high pressure" patients, one pale, the other red-faced, the difference being due to the condition of the vessels. The pale patient had general spasm of the circulatory system, the red-faced one a dilatation of the blood-vessels. Kidney troubles were thought to cause hypertension, but it appeared that in a number of cases kidney disease was the outcome of hypertension. It had been ascertained that in the pale type substances (peptones) producing arterial spasm circulated in the blood. In acute nephritis the kidney vessels were in a condition of spasm. In older persons the blood-vessels were less expansible, but had a greater capacity; the first condition increased blood pressure, the latter counteracted it, and the physiological diminution of cardiac force tended to keep the pressure down in older persons. It could be said that arterio-sclerosis was prevalent in persons whose hearts had remained young in spite of the changes in the blood-vessels due to age.

Prof. J. Pal stated that according to the generally accepted notion the level of blood pressure was proportionate—assuming constancy of blood volume and of cardiac efficiency—to the sum total of resistance offered in the arterioles and capillaries. The vessels in the intestinal organs especially played an important part in this connexion. Increased resistance (or narrowing of the lumen) in these vessels caused pressure in other regions, where less resistance was offered; the cerebral circulation was especially prone to passive congestion, accompanied at times by spasm in the cerebral arteries, if the congestion took place suddenly. Repeated attacks of increased blood pressure tended to produce a condition of

¹ See THE LANCET, March 31st, p. 668.

permanent high pressure, without manifestation of arterio-sclerosis visible at post-mortem examination. The vessels were hard to the touch during life, and offered great resistance to cardiac effort, but no anatomical lesion was discernible. Prof. Palex explained this condition by assuming an increased tonus of the cells; he called it "hypertonia," and thought it a disease sui generis, but often associated with and obscured by renal disease or arterio-sclerosis. It produced a hardening of the arteries, but the condition was amenable to treatment and might disappear if attacked in its early stages; the chronic form entailed disease of the kidney, of the pancreas, the brain, of the retina. Hypertonia was nowadays frequent, perhaps due to mental stress.

Other Circulatory Disorders.

Dr. Herxheimer (Wiesbaden) pointed out that diabetes was frequent in hypertonic patients; Prof. R. Schmidt (Prague) emphasised the rarity of carcinoma and tuberculosis in such cases. Dr. Lichtwitz (Altona) read a paper on severe trophic disturbances due to underfeeding, differing from cases observed during the war in that cedema was exceptional.

Prof. Knud Faber (Copenhagen) discussed the problem of blood-glycogen in diabetes. The percentage quantity in the normal blood, he said, was constant for each individual; in diabetic patients the organism had a tendency to maintain the same percentage proportion, which gave an important clue to therapeutic measures.

Prof. Schmidt had treated abnormal adiposity by injections of milk combined with thyroid gland by mouth, and had obtained excellent results—e.g., a loss of 2½ kg. in two days without any other dietetic measures. After attaining the desired drop in weight, the level could be maintained by prolonged thyroid treatment; exact differentiation of the cases suitable for this treatment was not yet possible.

The aetiology of hamatoporphyria was discussed by Dr. Weiss and Dr. P. Kammerer, who stated that it was not certain whether a nervous disturbance of metabolism or an infection of the liver was responsible. Prof. G. Singer (Vienna) demonstrated a case of scleroderma diffusa, which he treated with thyroid and ovarian extract, with excellent results. His observations, based on a number of cases, led him to explain this disease as a manifestation of hypothyroidism in the subcutaneous tissue, often associated with hypofunction of the germ-cells. The remedies were best given first by mouth, then by subcutaneous injections. Dr. Lichtenstern reported on his observations of 28 cases treated with transplantation of generative glands. In six cases the operation was performed for the purpose of counteracting the results of complete castration, done a long time ago. The results were most gratifying, the psychic and physical functions being restored. In the majority of favourable cases the results were lasting; in one patient eight years had already elapsed since the operation. In some cases, only temporary relief or improvement was obtained.

Pathology of Internal Secretion.

One afternoon was devoted entirely to demonstrations of the pathology of internal secretion. Prof. Pirquet showed children with premature development of sexual characters (3½ years old), a girl of 10 years, normally developed, who was born weighing only 790 g. (26 oz.), a girl with regional absence of the subcutaneous fat, a case of early scleroderma; all these patients showed abnormalities of the glands of internal secretion. Dr. B. Aschner showed females suffering from "physiological disturbances," as he termed them, of these glands. He included anaemia, chlorosis, adiposity, and amenorrhoea under this expression, and proved that by organotherapy and repeated venesections very good effects were obtained. A case demonstrated by Prof. W. Falta, showing a tumour of the hypophysis, was a real acromegalic giant, whilst Dr. Bauer discussed the mechanism of dwarfism, and demonstrated a number of dwarfs

whose condition was due not to inhibition of the thyroid function, but either to premature ossification of the epiphyseal site or to lack of growth stimulus. Most of these patients stopped growing after suffering from some infectious disease; one had suffered from a deforming arthritis since his seventh year, one had been attacked by an inflammation of the vertebral column. A woman, aged 41, had lost all her hair and nearly all subcutaneous fat within three months, her weight going down from 70 kg. to 40 kg. after an attack of influenza. A young man had also been attacked by influenza (? encephalitis lethargica), and had since that time developed marked gigantism. Prof. Falta showed a few cases of complete loss of hair on the body and nearly complete absence of the eyebrows and eyelashes, with very marked asthenia. Treatment with thyroid and ovarian tablets was most effective. Abnormalities of hair growth were demonstrated by Prof. Redlich, and Prof. J. Wagner-Jauregg showed dystrophic conditions, chiefly affecting the subcutaneous fat, caused by encephalitis.

On the last day of the congress devoted to scientific discussions over 80 speakers took part. No more than four minutes were allotted to each speaker, with the exception of introducers of a subject. Dr. Königsfeld pointed out the importance of the skin as a means of protection against disease, and to the production of protective substances against carcinoma by the actinic rays. Dr. Herrmann (Carlsbad) had found that by elevating the abdomen and legs it is possible to relieve the excruciating pain of gall-stone colic. Profs. Hofbauer and Wenckebach obtained similar results by turning the patient quickly on his right side, and thus "squeezing out" his liver by means of the diaphragm. Dr. Rostocki (Dresden) had observed a marked frequency of pulmonary cancer amongst miners; in Vienna, Hamburg, and Königsberg, bronchial cancer, formerly rare, is now found fairly often. Dr. Götze (Frankfort) stated that phrenicotomy is often most effectual in pulmonary phthisis, and much more advisable, because of its simplicity, than the repeated production of artificial pneumothorax. Treatment of pulmonary tuberculosis with tuberculin by the percutaneous method was strongly opposed by many experts.

An exhibition of apparatus and drugs was held during the congress, all the latest developments of electro-therapeutic, actinic, and optical work being on view.

CZECHO-SLOVAKIA.

(FROM OUR OWN CORRESPONDENT.)

The Peace of the Red Cross.

ON March 31st, "White Saturday," the "Peace of the Red Cross" was solemnly promulgated in a special session of Parliament. This Easter-time ceremony has now been held for three successive years; the idea was conceived by Dr. Alice G. Masaryk, daughter of the President of the Republic, who is the president of the Czecho-Slovak Red Cross; at Easter this organisation makes a great and increasingly successful effort to stop all political quarrels and discussion and to interest the public in social and public health questions, in a manner recalling the mediæval Truce of God. This year's response from the daily press and the public was remarkable; the Easter Sunday papers contained articles on public health and social topics written by prominent politicians, by party leaders, by highly-placed State officials, and by scientific authorities. This part of the Red Cross campaign was purely educational, no appeal for money being made. A "drive" for funds will follow in May, in cooperation with the Tuberculosis League, the Venereal Diseases Society, and the Abstinence League. At a recent meeting of the League of Red Cross Societies the Czecho-Slovak delegates proposed an extension of the idea of a Peace of the Red Cross to all States represented in the League.

Social Insurance Legislation.

The Social Insurance Bill dealing with sickness, invalidity, and old age insurance has been introduced into Parliament to be considered during the summer session. It represents one of the most difficult problems which have confronted the present Coalition Government. The preliminary studies undertaken by the Ministry of Social Welfare occupied more than a year. A permanent committee composed of political and professional workers drafted the Bill; the Parliamentary procedure will probably take at least seven months, but it is hoped to put the Bill into effect on Jan. 1st, 1924. The terms of the Bill are very complicated, comprising over 300 sections. The insurance will cover not only the working class but also persons of independent means up to a certain figure. A voluminous report has been prepared in connexion with the measure, and a special memorandum on the statistical aspect of the problem is being printed. The insurance will include 3,200,000 workpeople, and will involve a yearly expenditure of 1½ milliards of Czecho-Slovak crowns. The main lines of the Bill were drafted by Dr. L. Winter, who was the first Minister of Social Welfare in the independent Republic.

Treatment of Alcoholism.

The Czecho-Slovak Abstinence Society is about to open a home for alcoholics at Tuchlov, near Teplice. Assisted by the Ministry of Health, the society bought for this purpose a small castle set in attractive surroundings and requiring no adaptation. There is room for 50 inmates; treatment will be both medical and educational, and although residence will be compulsory, everything possible will be done to avoid the creation of a prison atmosphere.

A New Medical Curriculum.

The medical press is discussing the suggested reforms in the medical curriculum which was drafted by Prof. Jaroslav Hlava, the doyen of the medical profession in Czecho-Slovakia. Prof. Hlava detailed his plan at the first congress of Czecho-Slovak University teachers, held in May, 1922. It was then decided that a special committee should be appointed to work out definite plans for reform on the basis of Prof. Hlava's scheme. The suggested reform would not alter the time—five years—now required for completion of the medical course, but a compulsory "practical year" for all doctors of medicine will be introduced, and will automatically prolong the study of medicine by another year. Prof. Hlava prescribes for the first four semesters the theoretical study of basic medical sciences, and for the fifth semester preliminary instruction in internal and external medicine. The remainder of the curriculum he proposes to devote to clinical studies. The greatest innovation, however, is Prof. Hlava's scheme for examinations, which would be in groups, the first group to be taken before Christmas in the fifth semester, the second to be taken at the end of the eighth semester, the third group to be begun at the end of the tenth and finished in the eleventh semester. The successful candidate would then have the right to use the title of physician. The degree of doctor of medicine would only be obtainable after presentation of a scientific thesis, according to the French system. This last provision is the only one to which any considerable exception is taken by medical men.

A COUNTRY HOUSE HEALTH RESORT.

On April 27th the new sanatorium at Rendlesham Hall, Wickham Market, Suffolk, was inaugurated by a luncheon at which were present many distinguished medical and lay visitors including Mr. W. Bingham, chairman of the undertaking; Sir Alfred T. Davies, of the Board of Education; Mr. F. W. Raffety, L.C.C.; Rev. E. J. Barston, chairman of the London Congregational Union; Rev. J. A. Sharp, ex-chairman

of the Wesleyan Conference; and Mr. Tom Wing. The following representatives of the medical profession were also present: Sir Humphry Rolleston (President of the Royal College of Physicians of London), Sir Sydney Russell-Wells, M.P., Lady Barrett, Dr. Jane Walker, Sir Robert Armstrong-Jones, Sir William Willcox, Sir James Purves-Stewart, Mr. McAdam Eccles, Dr. J. Burnett Rae, Dr. Basil Price, Mr. H. L. Sackett, Mr. W. E. M. Mitchell, and the representative of THE LANCET.

The objects of the sanatorium are to treat cases of alcoholism and drug addiction under conditions approximating to those obtained in an ordinary health resort. Experience has taught that there are a large number of people who are desirous of treatment so long as they can have the treatment in a home-like environment, and here at Rendlesham Hall the work that has been carried on for nearly 20 years at Beckenham Park will be continued under improved conditions, the increase of work necessitating the expansion of premises. The lease at Beckenham has 3½ years to run, and the work will be conducted at both institutions for that period.

At the luncheon Mr. Bingham, the chairman, spoke of the increasing pressure of cases and the need for their individual and sympathetic care in a suitable environment, such as Rendlesham Hall. Sir Sydney Russell-Wells told the story of Rendlesham Hall, a mansion with a curious social interest. Peter Thellusson, a banker, after acquiring great wealth, died in 1797 and his will directed that the major part of his fortune should accumulate during three generations and that the sum thus accumulated, estimated at several millions, should be used to purchase an estate for the then eldest lineal descendants. But the will, as everyone knows, was set aside by the courts, and in 1859 it was decided that the property should pass to the late Lord Rendlesham, the oldest male descendant of the banker's eldest son. The house, he said, had arisen on the very site where Thellusson had woven his ambitious schemes and had become a sanatorium—for the banker's dream of social conquest for his descendants by the power of accumulated wealth there would be substituted the greater work of healing the afflicted.

The guests at the luncheon inspected the house and grounds. The original estate consisted of some 5000 acres with 277 acres of park land. It is the park land which has now been purchased with the freehold of the Hall, which is fitted up as a large and luxurious country home. No less than 45 bedrooms are already prepared for occupation and 10 more will shortly be available. Here, in a beautifully wooded country, the windows face noble clumps of trees and smooth lawns, and the aim of the management is to secure for patients during their sojourn the amenities of a country mansion managed on the lines of a first-class hotel. The treatment is voluntary, patients being able to come and go as they like, but a six weeks' course of treatment is recommended. Luxurious carpets are everywhere in evidence, those for the stairs and corridors alone cost some £1250; the rooms are lofty, the drawing-rooms lead into a winter garden and conservatory, are elegantly furnished, and face the beautiful prospects; there are a fine billiard-room, smoking-room, and every facility for indoor recreation, while outdoors there is a small private golf course, as well as tennis courts and croquet lawns. In addition, there are 5½ acres of walled-in garden. At present there is a central heating instalment with wood fires for the bedrooms. Electricity is used for lighting, and later this agent will be utilised for radiators in the bedrooms. The water-supply is pure and abundant. The nearest village is 1½ miles from the Hall.

The treatment will be carried out under the direct management of Dr. W. Asten, who is a barrister as well as a medical man, while Dr. Francis Hare, the medical superintendent at Beckenham, will be the consulting physician. The charges are from 7 guineas to 15 guineas a week.

Correspondence.

"Audi alteram partem."

ANAPHYLAXIS AND THE ADMINISTRATION OF SERUM.

To the Editor of THE LANCET.

SIR,—I have read with great interest Dr. Poul Iversen's article on this subject in THE LANCET of April 7th. Nowadays it is the fashion to ridicule the "bugbear of anaphylaxis"; rare though it may be, the danger is still a real one, and when anaphylactic shock does happen it is such a dreadful calamity that no avoidable risks should be run. It is small consolation to a grieving mother to point to statistics, and to demonstrate how exceedingly unfortunate it is that such an unlikely accident should have happened to her particular child.

My own experience is as follows. I first began to use serum on a large scale in 1908 for the treatment of bacillary dysentery in Egypt and among the Mecca pilgrims at El Tor. From 1909 to 1914 I was engaged in the preparation of this serum for the Service Sanitaire Maritime et Quarantenaire d'Egypte, as well as in its administration. During part of the late war I was in charge of the dysentery department of a large general hospital in Egypt, and I have had occasion to treat many cases of bacillary dysentery during the past two years. Consequently I am in the position to record my impressions from the administration of many thousands of injections (though, unfortunately, I cannot give exact figures) of serum prepared by myself, the Lister Institute, Burroughs Wellcome and Co., the Institut Pasteur, the Istituto Sieroterapico of Milan, the Serum Institute of Berne, the Institut für Infektionskrankheiten of Berlin, and others; and I affirm unhesitatingly that I have never given an intravenous injection of serum without experiencing feelings of the most acute apprehension. It is true that I have not yet experienced a fatal result in my own practice from the administration of serum by any route, but I can recall many instances in which a fatality was, to all appearances, only averted by the narrowest possible margin; in fact, I think several patients would have died but for my invariable rule of having stimulants always at hand, and a syringe ready loaded with 10 minims of adrenalin and 1/75 gr. of atropine in every case of intravenous injection and in all cases of intramuscular injection where I had any reason to suspect sensitisation. On the other hand, a death from typical anaphylactic shock actually occurred in 1918 in the practice of one of my colleagues of a man who had been sensitised by the injection of no more than 0.75 c.cm. of serum contained in two doses of sensitised dysentery vaccine; and the first two horses whom I started to immunise in 1909, by means of intramuscular followed by intravenous injections of dysentery vaccine, also died with classical symptoms of anaphylactic shock. I subsequently abandoned intravenous injection and lost no more.

I quite agree with Dr. Iversen that different batches of serum differ widely in their toxicity, and I have found that the longer the serum has been kept—especially in hot countries—the greater has been its toxicity. Further, the addition of any antiseptic appears to enhance this property. On the other hand, all my cases exhibiting untoward effects have been adults; perhaps I have been exceptionally fortunate, but I do not remember ever to have had a moment's anxiety in the case of a child, although I have often given 40 c.cm. in a single dose to infants of less than a year old.

Further, Dr. Iversen does not appear to differentiate sufficiently clearly between the different types of reaction which may occur. In my experience these have been:—

1. Definite anaphylactic shock, which is seen far more commonly after intravenous than after intramuscular

injection. This takes place either during or shortly after the injection, and is characterised by sudden air-hunger, coughing, tingling in the hands and feet, often vomiting, and syncope or convulsions. *There is no urticaria*, and none of the ordinary symptoms of serum sickness, such as fever, a rash or joint pains. This condition is always dangerous, and often fatal.

2. A rigor, which in my experience has always begun with curious precision exactly 20 minutes after the commencement of an intravenous injection; it is followed by hyperpyrexia, and may occur whether the serum be injected undiluted—e.g., after 120 c.cm.—or diluted with saline or gum acacia saline. It is alarming in appearance, but not dangerous, and in fact may be of good prognostic import.

3. A precipitate serum reaction, which may show itself within an hour of injection. This is characterised by an intense urticaria, a generalised erythematous rash, vomiting and collapse. In the case of "horse-asthmatics," who are particularly liable to this form of reaction after an intramuscular injection, the condition may be dangerous from the violent asthma which may accompany it. If the injection be given intravenously, the condition described in section 1 may occur; I have still a vivid recollection of one such case in 1918, who was admitted to my wards apparently moribund after spending nearly 24 hours in an isolated latrine before being discovered. An intravenous injection of gum acacia saline was first given, and then serum was very cautiously added; he could not have received more than a c.cm. or so when violent coughing and air-hunger, followed by collapse, supervened. For more than an hour I thought he was dead, but he rallied after adrenalin and atropine, oxygen under pressure, and artificial respiration. Subsequently, he received several large intramuscular injections of serum, and made a complete recovery. A curious sequel to this and one other similar case was that neither man had a recurrence of asthma as long as I was able to observe them; possibly they had been desensitised.

4. The ordinary serum reaction, which usually occurs from five to ten days after the injection of serum intramuscularly. This is so well recognised that no description of it is needed, and in my experience at least it is never dangerous. It is particularly prone to be severe after old serum has been given, but is no contra-indication to further injections of serum even when present—thus differing from true anaphylactic shock.

Again, Dr. Iversen appears to deny the value of desensitisation; this seems to me to be a most dangerous doctrine to preach. Subsequently to 1917 nearly all my patients have received previous injections of serum for wounds, diphtheria, dysentery, or in sensitised dysentery vaccine; the fatal case above recorded, and all my own cases who nearly died, had not been desensitised, whereas I cannot but attribute my immunity from anxiety in other cases to the meticulous care with which desensitisation has been carried out as a routine practice.

In conclusion, in my experience the intramuscular injection of serum should remain the route of choice as being almost as efficacious as, and far safer than, the intravenous. It is obvious that desperate diseases require desperate remedies; in such cases the risks incidental to the intravenous route must be taken, although even then I shall continue to desensitise by the injection intravenously of four doses of $\frac{1}{2}$ to 1 c.cm. at intervals of 15 minutes.

I am, Sir, yours faithfully,

J. GRAHAM WILLMORE.

Chelsfield, Kent, April 30th, 1923.

INSURANCE PRACTICE.

To the Editor of THE LANCET.

SIR,—One sentence in the letter from "Rusticus" in THE LANCET of April 21st, p. 819, hits the right nail on the head as far as the country panel practitioner is concerned.

"It was easy to see that the regulations were framed for the town practitioner, that some of them were next to impossible in the country."

I may be wrong, but I venture to think that when the thousand and one rules and regulations of the National Insurance were framed, no pukka representative of the country panel practitioner had a say in it. Now many of these rules have been cancelled, augmented, diminished to such an extent that what might have been harmony is cacophony.

The professional work of the real country practitioner on the panel is quite different from that of the town practitioner. Many of the diseases may be the same, but the work entailed to treat and visit these cases, to give certificates, and so on is very different from that of a practitioner who has a large panel within a half-mile radius.

"Rusticus" says, "Anyhow, thank God, I am a country practitioner!" I agree with him and clasp his hand over it. But when new regulations and rules materialise, if they ever do, we country panel practitioners must have a bigger say than we have had heretofore.

I am, Sir, yours faithfully,

R. T. RICHMOND.

Seascale, Cumberland, April 23rd, 1923.

TUBERCULIN IN PRIVATE PRACTICE.

To the Editor of THE LANCET.

SIR,—In a paper published in THE LANCET of March 1st, 1913, I gave a Summary of 340 Cases of Pulmonary Tuberculosis, treated during 25 Years Practice, treated with and without tuberculin. In tabular form the results were as follow:—

In 100 Cases Treated without Tuberculin.

Arrest of disease.	Improvement.	Loss of weight and febrile conditions continuing.	Advanced stage.	Continuation of treatment in sanatoriums and elsewhere.	Deaths.
23	29	21	7	12	8
In 100 Cases Treated with New Tuberculin, T.R.					
25	30	21	6	13	5

From August 1st, 1911, to August 1st, 1921, I treated 200 cases of pulmonary tuberculosis by serial tuberculin administration. The dilutions used were, first, six dilutions of P.T.O.; next, four dilutions of P.T.; and next, two dilutions of Koch's old tuberculin, albumose-free. Injections were given at first twice weekly, then once a week, and afterwards once a fortnight. In the absence of reaction each successive dose was double the preceding; in the event of a rise of temperature the previous dose was repeated. Put in tabular form these further results are as follow:—

In 200 Cases (two untraced) Treated with P.T.O., P.T., T. (Albumose-free) Sequence.

54	80	17	5	33	9
or divided by two to compare with the percentages of the former series—					
27	40	8.5	2.5	16.5	4.5

Of the deaths at least two out of the nine were due to other causes than pulmonary tuberculosis. In two cases efforts to trace, hitherto unsuccessful, are being continued.—I am, Sir, yours faithfully,

Southport, April 17th, 1923. J. C. VOIGT, M.D. Edin.

SPASMODIC DYSMENORRHOEA.

To the Editor of THE LANCET.

SIR,—In Dr. G. Blacker's contribution on the treatment of spasmodic dysmenorrhœa, in your issue of April 21st, there is not one word about the neurotic basis of this symptom. Can it be that gynaecologists have not yet realised that spasmodic dysmenorrhœa is a manifestation of anxiety hysteria? The exact causation is not uncertain, as Dr. Blacker states; it is always hysterical and other hysterical symptoms nearly always co-exist. Even in the old days this condition was frequently cured by hypnosis and now it can always be cured by psychoanalysis. I have even had patients under psycho-analytical treatment who have told me that I had

cured this symptom, although previously I never knew that they suffered from it. Every case of spasmodic dysmenorrhœa is one of anxiety hysteria curable by psychological methods, and those patients who are cured by operation are cured by suggestion of a very potent character. It would not be far wrong to say that the converse is also true—viz., that every case of anxiety hysteria suffers from spasmodic dysmenorrhœa.

I am, Sir, yours faithfully,

W. H. B. STODDART.

Cavendish-square, W., April 24th, 1923.

PRACTICE ABROAD.

To the Editor of THE LANCET.

SIR,—The reference in your issue of April 7th to our now extinct Continental Anglo-American Medical Society (which personally I greatly regret) prompts me to call the attention of your readers to the fact that within the next few years there will be a number of vacancies for English practitioners in France and sundry other countries. I have remarked that as English doctors practising abroad die out their places are not taken by other Englishmen, no doubt for the simple reason that since the tightening up of the conditions of acquiring the right to practise in France no Englishmen holding the French qualification are available—a fact much to be deplored in the interests of the travelling British, and I may add American, public, comparatively few of whom are familiar with the language.

Given a knowledge of the French language—which can easily be acquired when young by spending a few terms in a French school or even by passing the holidays in a French family—there is no particular difficulty in acquiring the right to practise. The one essential thing is to pass the French *baccalauréat*, but this I presume would be accepted by English university authorities as the equivalent of the matriculation examination. It is necessary to pass *all* the examinations one by one, but if this be done concurrently with the English curriculum no particular difficulty need be experienced, at most a few weeks' coaching by a French tutor.

Life in French watering places and health resorts is distinctly agreeable, and practice there offers many advantages. Parents who contemplate a medical career for their sons might well consider the practicability of giving it a French twist.

I am, Sir, yours faithfully,

Algiers, April 24th, 1923.

ALFRED S. GUBB, M.D.

OPERATIONS ON TONSILS AND ADENOIDS: A POSSIBLE DANGER.

To the Editor of THE LANCET.

SIR.—The escape into the mouth of extracted teeth or other foreign bodies is well known to be an accident against which precautions must be taken in dental operations, but I do not find that much attention has been paid to the existence of a similar danger during other operations involving the use of instruments within the mouth, particularly for the removal of tonsils and adenoids in young children. On making the usual inspection beforehand one often finds loose milk-teeth, and hitherto I have, as I believe is customary, usually been content with noting them for avoidance in inserting the gag. The presence of such a tooth is, however, inconvenient, and there is always risk that in the course of the operation it may be dislodged; it is then apt to be lost in the blood, and there will be some concern until it is recovered, for dropping into the throat and inhalation into the air-tube (as in dental cases) is by no means unlikely. Some years ago Sir St. Clair Thomson recorded fully¹ a case, originally a dental one, in which (after consulta-

¹ Practitioner, August, 1918.

tion with Sir James Dundas-Grant and Mr. E. D. D. Davis) he removed, by lower bronchoscopy, a tooth impacted in a secondary bronchus. Two attempts by upper bronchoscopy had previously been made. References to other cases are given and an interesting medico-legal question raised as to the responsibilities of the operator and anaesthetist respectively.

I would, therefore, advise that such teeth should be removed *before the operation is begun*, the need for so doing being explained to the parents, who may otherwise suppose there has been carelessness or clumsiness.

I am, Sir, yours faithfully,

London, N.W., April 20th, 1923.

J. D. MORTIMER.

TUBERCULOSIS OF SACRO-ILIAC JOINT.

To the Editor of THE LANCET.

SIR,—After reading Mr. H. C. W. Nuttall's interesting paper in THE LANCET of April 28th, it becomes evident that he wrote it prior to the publication of Dr. A. Rollier's "Heliotherapy," which you review on another page of the same issue. How else could he make the statement that "the rarity of the disease precludes the possibility of impressive statistics"? In Appendix III. of that book, on pages iv. and vi., are statistics of no less than 83 cases of this condition which Dr. Rollier has personally treated at Leysin.

As Mr. Nuttall recommends still more radical methods of treatment than have been used in the past, it may be of interest to your readers to glance at the actual details of Dr. Rollier's figures, which for the sake of brevity I have combined in one table.

Cases of Sacro-Iliac Disease treated by Heliotherapy.

—	Total.	Healed.	Improved.	Stationary.	Died.
Without sinuses ..	40	36	3	—	1 (r)
With sinuses ..	43	21	9	8	5 (a)
—	83	57	12	8	6

(r) = affected with renal tuberculosis.

(a) = affected with amyloid degeneration on arrival.

I am, Sir, yours faithfully,

PAUL BERNARD ROTH.

Harley-street, W., April 28th, 1923.

SYPHILIS OF THE MEDIASTINUM.

To the Editor of THE LANCET.

SIR.—If it is not too late to return to the subject, I would thank Dr. Renton for his kindly rejoinder to my letter in THE LANCET of April 14th. I fully realise that he has authority on his side in saying that there is gross displacement of the heart in cases of mediastinal sarcoma, but authority is, I believe, in this case wrong. Lest I had deceived myself, I asked my house physician, Dr. J. Whitby, to look up the post-mortem records of a few recent cases of mediastinal sarcoma at the Victoria Park Chest Hospital. He has done so, with the result that in no case was the heart displaced to any appreciable extent, and if displaced at all, was slightly towards the side of the main mass of the growth. In two cases which I have seen recently in private, there was also no cardiac displacement. Therefore in six cases, five of which had histological confirmation, seen within little more than 12 months, this sign was definitely negative.

As I wrote before, the question of the frequency of the occurrence of syphilitic lesions in the lungs and mediastinum is a controversial one, and is, moreover, one of such great importance that any published cases of this condition require incontrovertible proof.

I am, Sir, yours faithfully,

Harley-street, W., April 27th, 1923.

F. G. CHANDLER.

Public Health Services.

THE RURAL PRACTITIONER'S NEEDS.

"Rusticus" has aroused an echo from another country panel practitioner. Dr. R. T. Richmond reminds us in his letter in the present issue that the work of the rural practitioner is in many respects different from that of his colleague in the towns. We may frankly add that it is often more difficult. In the country the proportion of visits to consultations at the doctor's surgery is known to be greater than in urban practice. The nature of the work is more arduous and the responsibility of the practitioner is greater, because the hospital and its staff are not so easily accessible. Nevertheless, the agricultural worker is an important asset to the State, and it is no ignoble task to take part in arresting the steady stream of country-bred labourers to the industrial centres, and in making the conditions which must tend to reverse the direction of the stream. The countryside is the proper nursery of an A1 population, and for this reason the status of the rural practitioner is a matter which the State cannot afford to ignore. It is when we come to consider the suggested remedies that the real difficulties are encountered. In a uniform national scheme, administered from a central office, it is not easy to see how a fair discrimination can be secured. Dr. J. P. Williams Freeman, the champion of the country practitioner, is in favour of an "extra grant." But extra grants were condemned by the Geddes Committee, and in the present financial stress the Treasury cannot be expected to make them. Then the money must come from the central pool, and the problem becomes one of redistribution. The Distribution Committee might assess the rural areas on a more liberal basis; but this would be difficult so long as the Insurance Committee area is the unit and practitioners in that area are perforce treated alike. Any such scheme would naturally involve a reduction in the proportion of the urban areas. If individual practices are considered, then an elaboration of the mileage scheme would probably be the best solution. But the problem is bristling with difficulties.

THE WASSERMANN TEST AND THE RANGE OF MEDICAL SERVICE UNDER THE INSURANCE ACTS.

A hearing recently took place at Birmingham into the question whether the taking of venous blood as a preliminary to the Wassermann test for syphilis came within the range of medical service under Article 38 of the National Health Insurance Regulations. There was no dispute as to the facts. An anonymous female patient suffering from tertiary syphilis consulted an insurance doctor, and, knowing of his experience in venereal disease, asked him to take the necessary steps for the performance of a Wassermann test. The patient was an insured person on his list. She insisted on the non-disclosure of her name, to the extent of preferring to pay the specialist's fee of 5 guineas, but there was no other unusual feature of the case. The local medical committee came to the conclusion that the venepuncture was outside the range of medical service under the Act, on the ground that it was the proper work of a specialist and not that of a general practitioner of ordinary professional competence and skill; and the Insurance Committee agreed with the decision. The Court of Referees, which consisted of a barrister-at-law and two medical men, decided that intravenous puncture for obtaining blood for analysis was not to be regarded as of greater difficulty, say, than the passage of a catheter in the male. A practitioner not possessing the necessary aptitude could acquire it without difficulty. In places well provided with facilities for the treatment of venereal disease, a patient might admittedly obtain more skill at them than from his insurance doctor in this particular manœuvre, but to remove from the range of medical

service under the Acts services to be rendered to a patient so placed would be to whittle away the duties of the general practitioner to a degree inimical, not only to the policy of the Acts, but also to the best interests of the medical profession. Possible risk of failure was not a matter, in the Court's view, which should weigh against the general conclusion. That risk was common to many a service which insurance doctors are admittedly under obligation to perform should the patient require it.

MEDICAL SERVICE OF THE INSURANCE ACTS: JOINT STANDING COMMITTEE.

At the Plenary Conference of bodies interested in insurance medical service, held at the Guildhall, London, on Jan. 30th and 31st last, a Standing Committee was appointed to consider the various suggestions made during the Conference. This committee, consisting of six representatives each of approved societies and insurance practitioners, four of insurance committees, and two of pharmacists, has now held three meetings. At the first meeting on April 13th Dr. H. B. Brackenbury was unanimously elected chairman, and Mr. W. Gill Hodgson, clerk to the Liverpool Insurance Committee (not being a member of the Standing Committee), as secretary. The first meeting dealt with matters relating to the efficiency of service, foremost the question of surgery and waiting-room accommodation, the following resolution being passed unanimously:—

That, in order to carry out paragraph 8 (4) of Schedule I. of the Medical Benefit Regulations, where an insurance committee has received a complaint from any quarter, or from other cause has reason to question whether adequate surgery and waiting-room accommodation is provided either in specific cases or generally in its areas, it should, jointly with the Panel Committee, investigate the matter, and if the accommodation in any case is not found satisfactory, or is not made satisfactory, should refer the case to the Medical Service Subcommittee.

Sir William Glyn-Jones undertook to bring this decision before the Federated Associations of Insurance Committees, and Dr. Brackenbury to place it before the Panel Committees via the Insurance Acts Committee. At the second meeting the consideration of efficiency of service was resumed, and the meeting to be held to-day (May 4th) is to deal with the interpretation of the range of medical service to be given to insured persons.

THE LATE DR. J. K. STEWART.—Dr. John Kilpatrick Stewart, who died suddenly on April 15th, was a native of Ballymena, and received his early education at the Academy in that town. He graduated M.B., B.Ch. in 1915, with honours, at the University of Belfast and almost immediately afterwards joined the R.A.M.C., and was severely wounded while serving in France. After demobilisation he was appointed medical officer to the Randalstown District Dispensary, where he won the affection and regard of all classes of the community. He leaves a widow and three small children.

WORTHING HOSPITAL.—Lord Athlone visited Worthing on April 24th and opened the new wing at this hospital which has been erected at a cost of £7918. The scheme originated in 1919, the object being to establish a maternity ward, a paying patients' ward, and surgical wards as a war memorial. In declaring the new wing open, the Earl of Athlone said the maternity wards were meeting a great need. As to accommodation for paying patients, a large number of people could not afford to pay considerable sums to go into nursing homes during sickness, and many preferred to have a little more comfort than they would obtain in the general wards. There was a great need for these wards, and he hoped very shortly to be able to state that he had been able to start this kind of nursing home in connexion with the Middlesex Hospital. He expressed his pleasure in coming to visit the Worthing Hospital, which is a very old foundation. It commenced in two rooms as a dispensary in 1829, and removed to Chapel-road in 1844. The first portion of the present building was erected in 1881, and there were additions in 1887 and 1889, and in 1901 hospital was substituted for infirmary. The out-patients' wards were established in 1912 as a memorial to King Edward.

Obituary.

SIR SHIRLEY F. MURPHY, K.B.E., F.R.C.S. ENG.,
FIRST MEDICAL OFFICER OF HEALTH, COUNTY OF LONDON.

By the death of Sir Shirley Murphy, which took place on April 27th, at his home at Regent's Park, the country has lost a great exponent of the science of hygiene and epidemiology, and a public health officer whose 40 years of labour have left their mark in the greater well-being and health of the whole community, above all in London. Although he had reached the age of 74, he had, until two or three years ago, been actively and strenuously employed with the army duties which he had sought at once on the outbreak of the war, and had continued, with great public spirit and practically without intermission, until after the Armistice. It was only since then that signs of

SIR SHIRLEY MURPHY.

failing health had been conspicuous, and he had been crippled by severe attacks of neuralgia. He had continued, notwithstanding, to write and take part in affairs, as far as his health allowed, until a few days before his death.

Shirley Forster Murphy was born on May 21st, 1848. His parents were then living in London, and he was sent to University College School in Gower-street. Thence he went to Guy's Hospital, and qualified M.R.C.S. and L.S.A. in 1870. After brief tenure of a hospital appointment at Manchester he was advised, on the ground of suspected tuberculosis, to go abroad, and took two years of medical service in the East under the P. and O. Company. Returning to London, he was appointed an assistant medical officer at the Metropolitan Asylums Board hospital at Homerton, which at that period—the secondary wave of the great pandemic—was often congested with small-pox cases as well as with typhoid and other infectious diseases. Experience there led Murphy, in 1875, to the appointment of resident medical officer at the London Fever Hospital, then a great school for infectious fevers, with the recent traditions of Murchison and Sir W. Jenner. He remained resident medical officer, under Broadbent and Cayley as visiting physicians, until 1878. By that time, having become more and more

drawn to epidemiological and preventive questions—the London typhoid of the period, it may be remembered, was still a perpetual reminder to those who treated it of the effects of insanitary environment and the need for better hygiene in the metropolis—he adopted public medicine as a career and obtained the appointment of medical officer of health for St. Pancras, vacated by his friend Dr. Thomas Stevenson. The post offered an enormous experience and field for work, but the conditions under which improvements could be produced or disease prevented were almost heart-breaking. A few of the London vestries at that time gave moderate encouragement to the sanitary reformer, but none was to be found in this instance. A time came when reactionary opposition became so pronounced that Murphy decided that his energies should no longer be destroyed by it. Resigning from St. Pancras in 1884, he took the bold step of setting up in Queen Anne-street as a consultant in public health, with the aid of one or two minor official appointments, and for five strenuous years was busy with every branch of his subject. Since 1876 he had been secretary of the Epidemiological Society—an office which he held till 1888—while in 1879 he had become secretary of the Society of Medical Officers of Health. He worked these societies hard, developed them, produced subjects for discussion, and laid everyone under tribute on the epidemiological questions of the day—milk infection, small-pox transmission, vaccination evidence, periodicity of disease, epidemic diarrhoea, and many other matters. On these he frequently contributed original observations, while he was able to secure or interpret the views of such men as Buchanan, Ballard, Power, Longstaff, or, indeed, of almost any of the leading public health experts of that time, medical and non-medical, who freely took him into their confidence. He knew their work and enlisted their support in book-making, notably in the preparation of the manual, "Our Homes, and How to Make Them Healthy," published in 1884, to which many distinguished authors contributed, as was the case some years afterwards in the large treatise on "Hygiene" edited by Stevenson and Murphy. By foreign travel, which he continued in later life, he extended his circle of collaborators and made enduring friendships with foreign public health workers. He wrote much for different periodicals and began a long association with THE LANCET by contributions on public health policy and developments, which have been highly prized and by which this journal has greatly benefited. His zeal, special knowledge, and wide outlook became more and more appreciated. He had married, in 1880, Ellen Theodora, daughter of the late Henry S. King, J.P., and in this period, as throughout his whole life, his wife's keen intellect, industry, and sympathy were given him fully and unsparingly to aid his work. He had the advantage also at this time of special employment for Government departments, particularly for the Local Government Board and its medical officers—an association which lasted throughout his subsequent official career—while he added to his experience of small-pox and vaccination at the Animal Vaccine Establishment at Lamb's Conduit-street, where he was responsible for the preparation of calf lymph.

When the London County Council came into being, Murphy, with these qualifications, added to an intimate knowledge of London, its needs, its complicated public health organisation, and its many social and philanthropic agencies, had strong claims to the post of its first medical officer. This appointment, strongly contested as it was, he secured in 1889, and thereafter held for 22 years. It was one with many difficulties as well as opportunities—difficulties which were not lessened by the strong political bias, first on one side and then on the other, which characterised the assembly to which he was responsible, and the opposing political forces that operated in the other municipal bodies with which coöperation was necessary from the public health point of view. In the County of London the direct administration for which the medical officer of health was responsible under

statute, though more restricted in scope than in the case of large cities elsewhere, was of exceptional importance in view of the size of the metropolis and the special interests involved. But still more important was the surveillance of the public health work of other bodies, the new borough councils, and the various ad hoc administrations which characterise London municipal government—work of coördination, consultation, standardising, or action as complainant, referee or as a court of appeal—to which was added the duty of representing the position and health needs of London as a whole to the central government departments or to Parliament. Murphy developed both these functions, and established them on a sound and durable footing. In matters directly under his authority, such as the scheduling of unhealthy areas, the regulation of cowsheds, common lodging-houses, seamen's quarters, offensive businesses, and the like, he succeeded in instituting a highly efficient inspection service and office methods. A night visit with Murphy to London common lodging-houses, night shelters, and the haunts of vagrants was an education in itself, and an illustration of his close personal knowledge of this aspect of his work. On the other side, he gave himself freely to the mass of advisory and committee work, conferences, Parliamentary inquiries, bill-drafting, by-law and regulation making—and all the combats and discussion entailed therewith—which during his term of office have settled so much of the practice of public hygiene as it exists now in London.

Underlying all this work was a persistent effort to visualise London requirements and the condition of the London population as a whole. The epidemiological studies which he had begun early were never dropped from stress of official duties; they were enlarged on every opportunity with the wealth of material which was now at his disposal. That they were effective was due primarily to Murphy's own assiduity and the labours of Dr. Hamer, Dr. Young, and others of his highly capable staff, and also in no small degree to the position which Murphy came to occupy in the public health service. Men like Power at the Local Government Board, Whitelegge at the Home Office, and later Newman at the Board of Education; epidemiologists such as Theodore Thomson, Bulstrode, Chalmers, Reece, Buchanan, Greenwood—the list could be extended indefinitely—were always ready, in their esteem and friendship for Murphy, and for reciprocal benefit, to respond to his inquiries and undertake the studies he desired. For few great populations have the tendencies of diseases and variation of diseases, infectious and non-infectious, and the mass causes which have influenced them, been worked out so fully as in the reports which Murphy originated and his successor, Sir W. Hamer, has since continued. The consideration given to these matters was of the widest; social changes, migration of population, peculiarities of individual diseases in the matters of their recurrence and natural history, were reviewed and in proportion. These studies aided Murphy greatly in the efforts which he always made to look ahead and forecast, not merely from the scientific interest of foretelling epidemics, but from the practical point of view of being prepared for them. But in the whole series of reports there was no undue straining to claim credit for recent preventive measures, however promising; no propaganda; and no play to the political gallery.

We must be content with this reference to the greatest part of his life work. The health of London and his own official writings are the best evidence of its value. They had received recognition during his tenure of office by the knighthood conferred on him in 1904—an occasion of a striking demonstration of the regard in which he was held by the Society of Medical Officers of Health, over which he presided in 1891 and 1892, and again in its jubilee year 1905. They were also recognised by the grant of the honorary Fellowship of the Royal College of Surgeons, and the Bissett Hawkins medal of the Royal College of Physi-

cians in 1908. On leaving office in 1911—a retirement which he had himself been willing to accelerate by a year or two in order to allow of the fusion of the public health work and education medical services of the County Council—Murphy continued his epidemiological studies and gave further services to various public health organisations with which he had always been in touch, particularly in the Epidemiological Society, of which he had been president in 1894–95, then merged in the Royal Society of Medicine; at the London Fever Hospital; and more recently at the Metropolitan Asylums Board as the nominee of the Ministry of Health. He presided in 1912 over the section of Sanitary Service at the Congress of the Royal Sanitary Institute in York in 1912, giving a notable address on the decline of birth- and death-rates. He also took a keen and affectionate interest in the Society of Apothecaries, which he had entered (by apprenticeship to the late Sir George Buchanan) in 1870, and where he became a member of the Court of Assistants, and in later years (1920–21) Master of the Society. We may here note another honour in the closing years of his life, of which he was particularly proud—the receipt of the Jenner medal of the Royal Society of Medicine in 1921.

The outbreak of the war sent Murphy back to active official duties within a few days. He was a Lieut.-Colonel R.A.M.C. on the Territorial list for special sanitary service, and was at once attached to the London Command, where he worked as specialist sanitary officer throughout the war under four successive Directors of Medical Services. His knowledge of London and its public health arrangements, and his organising ability, were invaluable in the problems of billeting, transport, and arrival of troops, hygiene of quarters, and sanitation in all its aspects in relation to the large military area and the mass of soldiers quartered or passing through London, as well as with the problems of cerebro-spinal fever and other epidemics which arose from time to time during this period. His activity and devotion to this duty, which was practically continuous for four years, were greatly appreciated. An account of it will, it is hoped, be included in the official history of the war. For these army services he received the K.B.E. (Mil.) in 1918.

The following appreciation is from a well-known public health officer and epidemiologist:—"To his contemporaries the memory of Murphy will ever remain as that of a loved and revered colleague and friend. He accomplished much for his own time and has left a rich inheritance of example to those who will follow him in the ever-widening field of public health administration. This is not the occasion to consider his published work which advanced the standard of administration and afforded a pattern for much contemporaneous inquiry. We would rather ask what manner of man he was, what the personality of him who has gone from us; what the hidden springs from which during a long official life, all this energy flowed. For behind the work there lies the spirit of the worker, and it was this which endeared him to his colleagues and contemporaries. To him disease was no chance accident of life, but evidence of the working of laws which he set himself reverently to examine. He sought Nature in her own crucible and in the spirit of humility which marks the true worker.

"To such natures there comes now and again a glimpse—a suggestion rather—of the majesty of all Nature's laws. He was fond of the phrase 'a working hypothesis,' a rule to be tested by every new set of circumstances to which it might be applied, and modified if fuller knowledge disclosed defect. This theme runs like a chord through much of his published work, and it had many variants. It appears very early in his epidemiological studies; it reappears in one of his latest published addresses, as when at York in 1912 he applied it towards elucidating the movement of the birth- and death-rates. Law in nature was to him as a law of being. The spirit of service was also strong in him, and explains

much of the strenuous life he led. For him, to live was to serve, and herein lies the example for those who follow. Service to his fellows; service to England (as when during the war years and at an age when many might, without reproach, have been content as lookers-on, he undertook the duties of Sanitary Officer of the London Command); service to humanity, were dominant notes in his character. In many ways this spirit of service found illustration, but one recalls the succession of deserving lads who owed their start in life to his fatherly interest in them. It might be said also that the homeless and vagrant poor he regarded as his special care, for long before there was any organised provision of night shelters for them, he knew the number of those who nightly sought the companionship of their fellows under the stars on the Embankment, in the parks, or under the railway arches. It was social service of a high order, done characteristically, under the guise of official duty. Kindliness in thought and action pervaded his life."

Sir Shirley Murphy was buried at Brookwood cemetery on May 1st, after a service to his memory at St. Martin-in-the-Fields on the same morning, at which Lady Murphy and his two daughters, Sir H. Seymour King, and other relatives were present, together with many friends and representatives of public bodies.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Rear-Admiral W. Bett is placed on the Retd. List.
Surg. Capt. J. F. Hall to be Surg. Rear-Admiral.
Surg. Lieut.-Comdr. J. D. S. Higgins is placed on Retd. List.
Surg.-Lieuts. H. L. Douglas and J. T. Wylie to be Surg. Lieut.-Comdrs.

Royal Horse Guards.

Surg. Maj. E. D. Anderson, from Life Guards, to be Surg. Maj.

ROYAL ARMY MEDICAL CORPS.

Col. A. H. Morris, late R.A.M.C., retires on ret'd. pay.
Surg. Capt. G. O. Chambers, from Life Guards, to be Maj.
To be Capt.: Surg. Capt. A. B. H. Bridges (from Life Guards), and Capts. W. R. D. Hamilton and E. J. S. Bonnett (from R.A.M.C., Militia).

TERRITORIAL ARMY.

Maj. F. R. Harris is confirmed in his rank.
Maj. V. T. Carruthers (Res. of Off.) to be Maj.
Capt. F. G. Lescher (late R.A.M.C., Spec. Res.) to be Capt.
General Hospitals: The undermentioned relinquish their commissions and retain their rank except where otherwise stated: Lt.-Col. L. K. Harrison (Bt. Col.); Majs. G. W. Watson (Bt. Lt.-Col.), H. R. Dean, A. R. Hallam, and W. H. M. Telling (granted the rank of Lt.-Col.); Capts. J. le F. C. Burrow, P. Hamill (granted the rank of Maj.), W. R. Higgins, W. M. Munby, H. J. Slade, M. J. Stewart, C. W. Vining (granted the rank of Maj.), E. W. Assinder, J. Johnston, C. A. Moore (granted the rank of Maj.), H. B. W. Smith, H. E. Smith, W. C. Souter, and B. J. Ward.
Sanitary Companies: Capt. N. S. Golding relinquishes his commn. and retains the rank of Capt.
Supernumerary for service with O.T.C.: Maj. W. D. Sturrock ceases to be employed with the Field Amb. Section, Oxford University O.T.C. Lt. D. R. Wheeler ceases to be empld. with the Belfast University Contingent, Senior Div., O.T.C. Capt. C. H. Budd (late R.A.M.C., T.F.), to be Capt. for service with the Medical Unit of the Cambridge University Contingent, O.T.C. Capt. (local Maj.) W. Barclay resigns his commn. and is granted the rank of Maj.

ROYAL AIR FORCE.

Flight Lt. E. W. Longden relinquishes his temporary commission on ceasing to be employed.

TERRITORIAL DECORATION.

The King has conferred the Territorial Decoration upon the undermentioned officers: Lt.-Cols. J. Miller and S. G. Barling (General List, T.A. Res.); Majs. W. Y. Martin (ret.), J. A. H. Aitken, and J. R. Menzies.

Medical News.

UNIVERSITY OF CAMBRIDGE.—At examinations held recently the following candidates were successful:—

DIPLOMA IN MEDICAL RADIOLOGY AND ELECTROLOGY.

Part I., Physics and Electrotechnics.—Mahmoud Ahmed Affi, Narayan Mahadev Bodas, John E. Bowen, Burnett L. W. Clarke, Lionel R. G. de Glanville, Malcolm Frizell, Norman Gattellier, William H. Hastings, Joseph F. James, Mahadev Dattatraya Joshi, Anna T. Kellock, Jane S. Knight, Gabriel J. Luyt, Alexander G. MacLeod, Margaret J. Moir, Huggahalli Sundara Rajan, Alexander Ross, William H. Rowden, Jessie E. Sheret, Edward W. Twining, Sorab Byramji Warden, and Edward V. Whitby.

Part II., Radiology and Electrology.—Mahmoud Ahmed Affi, Eric G. Barker, John E. Bowen, Burnett L. W. Clarke, Harold K. G. Hodgson, Joseph F. James, Jane S. Knight, Huggahalli Sundara Rajan, William H. Rowden, James P. Thierens, and Edward W. Twining.

DIPLOMA IN PUBLIC HEALTH.

Dhirendranath Basu, Leila Savoja Chatterji, *Alexander J. Copeland, Nicholas D. Duzscombe, Elizabeth J. Findlay, Alfred T. Gaillon, Churchill H. Gunasekara, *James C. L. Hingston, †Spencer Hunt, Florence S. Kirk, Hilda L. Laidlaw, Frederick Lobo, Barbara R. A. Morton, Lalit Kumar Ray, Annabella A. Reid, Mary Russell, Beatrice M. Sellar, Yaimini Sen, and Annie E. Somerford.

* Distinguished in the application of Sanitary Science.
† Distinguished in the principles of Hygiene.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—A Hunterian lecture on Chronic Mastitis will be delivered in the theatre of the College in Lincoln's Inn-fields on May 9th at 5 P.M., by Prof. Geoffrey Keynes.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—An ordinary Comitia of the College was held on April 26th, the chair being occupied by the President, Sir Humphry Rolleston.

The following were elected to the Fellowship on the nomination of the Council: Dr. R. Hingston Fox, Dr. J. Porter Parkinson, Dr. D. W. Sutherland, Dr. D. G. Hall, Dr. W. S. Fox, Dr. J. C. H. Leicester, Dr. F. E. Tylecote, Dr. J. Owen, Dr. L. G. Parsons, Dr. John Parkinson, Dr. A. Hope Gosse, Dr. P. H. Manson-Bahr. Nominated by the Council under By-law XXI. (b): Sir Hugh Kerr Anderson and Dr. Byrom Bramwell.

The following were admitted as Members, having passed the required examination: Dr. C. Wm. Buckley, Dr. R. Coope, Dr. L. Cunningham, Dr. S. E. Denyer, Dr. J. D. H. Freshwater, Dr. Sylvia K. Hickson, Dr. R. Hilton, Dr. P. K. McCowan, Dr. A. Razik, Dr. M. E. Shaw, Dr. J. Stokes, Dr. G. B. White, Dr. V. R. Woodhill, Dr. F. H. Young.

Diplomas of L.R.C.P. were conferred upon 159 candidates who have passed the Final Examination in Medicine, Surgery, and Midwifery of the Conjoint Board and have complied with the necessary by-laws. The following are the names and medical schools of the successful candidates:—

C. Abbu, Madras; J. W. Alden, Oxford and St. Thomas's; F. G. Allan, St. Thomas's; D. D. Anderson, St. Bart's; Constance E. Appleton, King's Coll.; G. R. M. Apsey, Guy's; E. W. Arndt, Ceylon and Middlesex; N. Asherson, Univ. Coll.; Lucy T. Badcock, London; W. H. Bailie, St. Mary's; D. N. Balter, Vienna and St. George's; V. H. Barker, London; M. K. Barnett, Birmingham; Jessie H. Baxter, Univ. Coll.; A. H. Bennett, St. Bart's; H. W. Bland, Birmingham; B. Bourke, Dublin; C. G. Bowen, Guy's; J. F. Brailford, Birmingham; O. Brenner, Birmingham; T. F. Briggs, St. Thomas's; B. Broadbent, Cambridge and St. Bart's; F. Brockington, King's Coll.; W. A. Brown, Guy's; Dorothy E. B. Buckmaster, London; Helen Bumstead, Charing Cross; J. T. Burrell, Cambridge and London; Viole C. Cameron, St. Mary's; J. M. Clarke, Otago and Middlesex; Olive G. Clouston, Cambridge and London; E. Cohen, Leeds; R. S. Coldrey, St. Bart's; P. Connan, King's Coll.; W. F. Cooper, Cambridge and St. Mary's; Florence E. Cowlin, Charing Cross; D. W. Crombie, McGill and London; S. J. Davies, St. Bart's; M. Denman, Middlesex; V. P. de Zoysa, Ceylon and Univ. Coll.; H. T. Edmunds, King's Coll.; D. G. M. Edwards, Univ. Coll.; K. S. Ellis, Birmingham; Lucy M. Elsom, King's Coll.; Gwladys Evans, Cardiff and St. Mary's; M. W. H. Evans, Cambridge and London; V. F. Farr, St. Bart's; Emmie D. Fenwick, St. Mary's; Margaret Findlay, Cape and Royal Free; A. L. Finiefs, Paris and St. Mary's; G. H. Fitzgerald, Guy's; Annie Foner, Univ. Coll.; K. V. Francis, St. Mary's; Margery Freeborough, Royal Free and St. Mary's; F. W. Furniss, Cambridge and King's Coll.; P. C. C. Garnham, St. Bart's; Una Christina Garvin, Royal Free; Lena B. Gayer, Royal Free and London; L. Ghabrial, King's Coll.; Marjory A. Godfrey, Royal Free; S. J. Golden, London; Louisa P. Gordon, King's Coll.; Marion Greaves, Leeds; J. R. Hamerton, St. Bart's; L. W. Hamp, Birmingham; N. G. Harris, St. Thomas's; J. S. Hawes, London; Katharine M. Hick, Leeds; R. A. Highmoor, Cambridge and Leeds;

D. B. Hitchings, Guy's; J. Holroyd, Manchester; W. D. Hoskins, Cardiff and St. Thomas's; D. H. Hubbs, Guy's; Audrey M. Hughes, Charing Cross; L. D. A. Hussey, King's Coll.; R. Jackson, Cambridge and Middlesex; T. James, St. Bart's; M. Jayakar, Bombay and Univ. Coll.; A. Jephcott, St. Bart's; F. Lawrence, London; Ruth A. M. Leak, King's Coll.; F. H. Leekam, St. Mary's; P. Leftwich, Univ. Coll.; E. Linfoot, Leeds; A. R. Lister, Cambridge and London; N. L. Lloyd, Guy's; L. P. Lockhart, Cambridge and St. Thomas's; Marion Lones, Univ. Coll.; C. A. Lupton, Cambridge and St. Thomas's; C. R. McClure, London; Phyllis C. Mackenzie, Westminster; Kate Madders, Univ. Coll.; C. C. Maguire, Birmingham; J. Marley, Liverpool; Edith T. Marshall, Royal Free; Edith W. W. Marshall, Univ. Coll.; W. H. Marston, Birmingham; L. Mather, Manchester; Kathleen F. Matthews, Univ. Coll.; M. Mitman, Guy's; V. S. Monie, Madras and Edinburgh; A. J. Morland, Univ. Coll.; N. R. Mucadam, Bombay and Royal Free; E. B. Murrell, Cambridge and St. Thomas's; H. W. Needham, Cape and St. Bart's; F. W. Pare, Manchester; C. M. Pearce, St. Bart's; T. V. Pearce, St. Thomas's; J. P. Peel, Leeds; A. F. Percy, Guy's; J. W. Perkins, Calcutta and St. Mary's; J. H. Piddock, Birmingham; L. R. W. Price, Cambridge and St. Bart's; Gertrude E. Pugnaire, Liverpool; Margaret A. Quine, King's Coll.; R. P. Rees, Middlesex; Phyllis M. Rex, Royal Free and St. Mary's; M. M. Riad, Cairo; D. Riding, Liverpool; C. E. Roach-Smith, London; J. A. W. Robertson, St. Bart's; G. T. Robinson, Manchester; H. N. Rose, St. Bart's; May K. Ruddy, Charing Cross; A. Salama, Cairo; Edna M. Sanders, King's Coll.; D. H. Sarafian, Constantinople and Middlesex; Margaret V. Saul, King's Coll.; V. E. Schlesinger, Cambridge and Univ. Coll.; A. T. Schofield, Cambridge and St. Mary's; G. D. Shaw, Guy's; A. W. L. Smith, Manchester; C. N. Smith, Univ. Coll.; N. R. Smith, Sydney; C. F. V. Smout, Birmingham; E. G. Snaith, London; J. V. Sparks, Cambridge and St. Bart's; A. L. B. Stevens, Oxford and St. Thomas's; Ella M. Stratton, Royal Free; H. H. Sumption, St. Mary's; S. S. Suzman, Cape and Guy's; E. J. Targett and E. Thorpe, Birmingham; K. W. Todd; Olga F. Tregelles and Gladys M. Tullidge, Royal Free and St. Mary's; C. F. Turner, Birmingham; A. S. H. Walford, Cambridge and St. Thomas's; Marjory W. Warren, Royal Free; Constance C. M. Watson, Charing Cross; M. Weinbren, Guy's; L. E. H. Whitby, Cambridge and Middlesex; D. B. Whitlock, Guy's; M. C. Wilkinson and L. G. Williams, St. Thomas's; L. A. Willmott, St. Bart's; J. G. Wilson, Westminster; Lina Marie C. Wingfield, Royal Free; J. L. Woodhouse, Guy's; and M. I. Zimmerman, Westminster.

Diplomas in Tropical Medicine and Hygiene were conferred (in conjunction with the Royal College of Surgeons of England) upon the following 10 candidates from the London School of Tropical Medicine:—

R. Briercliffe, C. Cook, H. S. de Boer, M. L. Dhawan, C. H. Han, A. G. Harsant, C. de C. Martin, A. C. Rebello, R. H. Simpson, and E. Tagoe.

Diplomas in Public Health were conferred (conjointly with the Royal College of Surgeons of England) upon the following 20 candidates:—

E. B. Allnutt, St. Bart's and Royal Army Med. Coll.; U. P. Blackwell, Univ. Coll.; H. Carpenter, Royal Inst. Public Health; U. B. Cox, St. Mary's and Univ. Coll.; R. T. Edwards, St. Bart's; D. M. Jones, London and Royal Inst. Public Health; D. G. Karandikar, King's Coll.; H. T. Le Vieux, Guy's; E. K. Macdonald, St. Thomas's and Royal Inst. Public Health; E. O. Morphy, Dublin and Royal Inst. Public Health; W. W. Morrison, Middlesex; G. G. Naoleker, Allahabad and Royal Inst. Public Health; H. A. Osborn, King's Coll.; A. E. Quine, Univ. Coll.; J. L. Rebello, Bombay and Univ. Coll.; E. M. Reece, Univ. Coll.; F. A. Robinson, Durham and Royal Army Med. Coll.; S. K. Shenai, Univ. Coll.; K. Singh, Calcutta and Univ. Coll.; and G. Tate, King's Coll. and Royal Army Med. Coll.

Communications were received from the secretary of the Conjoint Board of Scientific Societies informing the College that the Board has been dissolved; from Mr. H. Wilson Holman offering for the acceptance of the College a memorial to the late Dr. William Musgrave, F.R.S., formerly in St. Leonard's Church, Exeter—the offer was accepted with thanks; from the Committee of the Centenary Celebration of the birth of Pasteur, being an invitation to the ceremonies to be held in Paris, May 24th to 28th, and in Strasbourg, May 31st and June 1st next. Dr. Morley Fletcher was appointed to represent the College.—A letter was received from the treasurer, Sir Dyce Duckworth, expressing his intention of resigning the office of treasurer in July next.—After notable tributes to the work of the Treasurer during his 39 years' tenure, of the office have been made by Dr. Sidney Phillips, Dr. Raymond Crawford, the Senior Censor, and Dr. Ormerod, the Registrar, the resignation was received with regret, all the Fellows standing.—Dr. Fawcett was re-elected, on the nomination of the Council, a representative on the Senate of the University of London.—Applications for restoration of the Membership, made in consequence of the recent alteration of the by-laws relating to Members, from Dr. E. A. Gates, Dr. Reginald Pratt, Dr. A. Gregson Williams, Dr. William McCallin, and Dr. M. K. Robertson were received and granted. After some formal business the President dissolved the Comitia.

UNIVERSITY OF LONDON.—At a recent examination for the Diploma in Psychological Medicine the following candidates were successful: Allen C. Hancock and William D. Nicol (with special knowledge of Psychiatry).

A lecture on the Psychology of Epilepsy will be given in the Robert Barnes Hall at the Royal Society of Medicine, 1, Wimpole-street, W., by Dr. E. D. Wiersma, professor of psychiatry and neurology in the University of Groningen, on Thursday, May 24th, at 5.15 p.m. The chair will be taken by Dr. Robert H. Cole. The lecture will be delivered in English. Admission free.

FEDERATION OF MEDICAL AND ALLIED SOCIETIES. The annual dinner of the Federation will be held at the Langham Hotel, Portland-place, London, W. 1, on Wednesday, May 23rd, at 7.15 p.m., when Sir Berkeley Moynihan, the President, will take the chair. Early applications should be made to the secretary, 12, Stratford-place, W. 1, for tickets, the price of which (exclusive of wine) is 12s. 6d. each.

GRANTOWN HOSPITAL.—In commemoration of her husband, Lady Seafeld has given a maternity ward to the Ian Charles Cothall Hospital, Grantown. The ward was formally opened on May 3rd by Colonel D. W. Cameron, of Lochiel. The ward has been built to the west of the main corridor of the hospital, with convenient access from the administrative and kitchen departments. It is planned to accommodate five patients. An X ray room has been constructed by the hospital trustees, and is housed under the same roof. The X ray installation, which was declared open also on May 3rd, was subscribed for as a memorial to the late Mrs. Hutchison.

MEDICAL SCHOLARSHIPS.—Fifteen medical entrance scholarships and exhibitions of an aggregate total value of about £1530, tenable in the Faculty of Medical Sciences of University College and King's College, and in the medical schools of Westminster Hospital, King's College Hospital, University College Hospital, the London Hospital, and the London (Royal Free Hospital) School of Medicine for Women, will be offered for competition on June 26th, 1923. Full particulars and entry forms may be obtained from the secretary of the London Inter-Collegiate Scholarships Board, S. C. Ranner, M.A., the Medical School, King's College Hospital, Denmark Hill, S.E. 5.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.—The syllabus of the post-graduate course to be held from May 7th–June 29th has now been issued. The course will consist of the following subjects. Lectures on the Pathology of the Nervous System, Mondays, 12 noon; lectures on the Anatomy and Physiology of the Nervous System (if sufficient entries are received); out-patient clinical teaching, Mondays, Tuesdays, Thursdays, Fridays, 2–3.30 p.m., and clinical lectures and demonstrations on these days at 3.30 p.m. Those taking part in the course include Dr. Hinds Howell, Dr. S. A. Kinier Wilson, Dr. Grainger Stewart, Dr. Risien Russell, Dr. F. M. R. Walshe, Dr. Gordon Holmes, Mr. P. Sargent, Dr. James Taylor, Dr. W. J. Adie, Dr. J. Collier, Mr. Leslie Paton, Dr. P. W. Saunders, Dr. Aldren Turner, Mr. T. H. Just, Dr. L. D. Bailey, Mr. S. Scott, Dr. Russell Reynolds, Mr. D. J. Armour, and Dr. J. Godwin Greenfield. Further information may be obtained from the Dean of Medical School, Dr. C. M. Hinds Howell, at the Hospital, Queen-square, Bloomsbury, London, W.C. 1.

THE IRISH WOMEN'S NATIONAL HEALTH ASSOCIATION.—The annual meeting of this National Health Association was held on April 27th. The Marchioness of Aberdeen and Farnham, who presided, said that it was intended during the coming autumn to hold a conference, to which representatives of public bodies and voluntary associations interested in the matter of public health would be invited. The condition of the country had made it somewhat difficult to carry on the work of their branches, but she had good reports from outlying districts, notably from Valentia Island, Waterford, Cork, Limerick, and Clare. Dr. Alice Barry submitted a report on the working of baby clubs and welfare societies in the city of Dublin. She said the mortality rate during the last year amongst children was 116 per 1000, compared with 163 per 1000 a few years ago. Through the babies' clubs they had distributed 12,666 gallons of milk at an average price of 5d. per quart. Dr. G. P. H. Sheehan, of the Peamount Sanatorium, in the course of his report, said that the institution had been entirely renovated. The great difficulty they had to contend with was the large number of advanced cases sent to them. At the beginning of last year the number of patients in the sanatorium was 33; during the year 373 were admitted, making a total of 366. Of these 347 were discharged, leaving 159 patients at the end of the year. A resolution was carried calling for a conference between the different organisations engaged in relief work in Ireland, for the purpose of arranging co-operation between them.

DENTAL BOARD OF THE UNITED KINGDOM.—The next session of the Board will take place on Wednesday, May 9th, at 2 p.m., when the Rt. Hon. Francis Dyke Acland, the chairman, will deliver an address, which will be followed by the hearing of disciplinary cases and consideration of other matters.

WHOOPIING-COUGH IN MANCHESTER.—During the last few weeks there has been an epidemic of whooping-cough in Manchester, and so far there are no signs of any substantial decrease in the number of fresh cases reported. In the week ending April 21st, there were 187 new cases and 13 deaths, as against 192 new cases and 12 deaths in the previous week from this disease. The number of cases of measles was 111 as against 105. Owing to the prevalence of infectious diseases, visiting of children in the Swinton schools by their relatives and friends is suspended until further notice.

INTERNATIONAL SOCIETY OF THE HISTORY OF MEDICINE.—At a meeting of the permanent committee of this Society, held at Antwerp on April 11th, it was voted to hold the Fourth International Congress of the History of Medicine at Geneva, Switzerland, during the third week of July, 1925. The following officers were elected: President, Dr. Charles Greene Cumston, Geneva. Secretary General, Dr. A. de Peyer, Geneva (Rue General Dufour, 20). President of Honour, Sir D'Arcy Power, London. Vice-Presidents of Honour, Dr. Edward B. Krumphaar, Philadelphia, U.S.A.; Dr. Tricot-Royer, Antwerp; Dr. J. G. de Lint, Gorinchem, Holland; Dr. Charles Singer, London; the President of the Geneva Medical Society for the year 1925.

THE LATE DR. CAMPBELL MACLEAN.—The death of Dr. John Campbell Maclean, at the age of 77, is a real loss to Swindon, and indeed to Wiltshire. Born in 1846, he took the M.B., C.M. Edin. in 1868, and began practice in Swindon in 1869, when it was almost a village, and developed a practice which eventually grew very large, for he endeared himself to his patients, and, moreover, his diagnosis was accurate and painstaking, and his treatment sound. His practice embraced places as far apart as Cirencester, Marlborough, and Malmesbury. He was surgeon to the Victoria Hospital, Swindon, and found time to keep abreast of the latest methods of treatment. He was an enthusiastic fisherman, was interested in boxing, and told a good story. The general esteem in which he was held was testified to by the numbers who attended his funeral.

ROYAL ACADEMY OF MEDICINE IN IRELAND.—On April 27th, in the hall of the Royal College of Physicians of Ireland, the Royal Academy of Medicine held a special meeting to confer its honorary fellowship on Dr. Ernest Hastings Tweedy, and to hear an oration by Dr. W. R. Fearon in honour of the anniversary of the birth of Pasteur. Sir Arthur Chance, President of the Academy, was in the chair, and among those present were the Presidents of the two Royal Colleges, the Provost of Trinity College, and the Council and Professors of the Royal College of Surgeons. In presenting Dr. Tweedy to the Academy, Dr. T. P. C. Kirkpatrick, general secretary, said that throughout the world Ernest Hastings Tweedy had won both for the Academy and for himself an honoured name. Sir Arthur Chance, in presenting the certificate to Dr. Tweedy, said that in one branch of their art Dublin held foremost place, for in the subject of obstetric medicine her fame was known all over the civilised world. By his original and valuable investigation, his lucid teaching, and his public work Dr. Tweedy had advanced and maintained the reputation of the Dublin school of medicine. An oration dealing with the life-work of Pasteur was then delivered by Dr. Fearon.

NEED FOR MATERNITY HOMES.—Addressing a meeting in Manchester on April 24th, on the Need for Maternity Homes, Dr. Frances Ivins said that though a material reduction had been effected in the rate of infant mortality in this country, there had been no corresponding decrease in the death-rate caused by childbirth, which remained what it was 30 or 40 years ago. Now that midwives were obliged to call in medical assistance, when this was required, the conclusion the speaker arrived at was that the cause was mainly the lack of sufficient ante-natal care of the expectant mother. Women must organise, beginning with the home, and see that everything was right there in the first place. The establishment of special clinics where pregnant women might be advised whether or not they were in a normal condition was advocated. Those suffering from abnormal symptoms should be retained and transferred to special maternity homes. To this end the general reluctance of women to submit to ante-natal examination, and to leave their homes for confinement, should be overcome before everything. The financial difficulties were not insuperable. If women themselves were prepared to organise the problem was as good as solved.

BRITISH CONGRESS OF OBSTETRICS AND GYNÆCOLOGY.—The next Congress will be held in London in 1925, one of the subjects for discussion being the Treatment of Puerperal Blood Infections.

ABERDEEN ROYAL INFIRMARY: RESIGNATION OF SIR HENRY GRAY.—At a meeting of directors of the Aberdeen Royal Infirmary held on April 25th, a letter to the chairman from Sir H. M. W. Gray was read, stating that he had been appointed chief surgeon to the Royal Victoria Hospital, Montreal, and desired to be relieved of his duties at the infirmary. The resignation was accepted with much regret.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—The financial position of this institution according to the 106th annual report, which deals with the year 1922, shows some improvement, for an accumulated deficit of £840 has been liquidated with a small balance of £88. The total income was £8823 and the expenditure £7893. The number of in-patients treated during the year was 874, and the average daily number of beds occupied was 36.68 out of a maximum establishment of 42 beds. The average stay was 15.2 days. The new out-patients numbered 15,095 and the casualties 1897. There were 35,479 attendances in all, and upwards of 4000 pairs of spectacles were prescribed.

THE NURSES' CO-OPERATION.—The thirty-second annual report of this institution, dealing with the year 1922, shows that there were 365 nurses on the general staff and 34 asylum-trained nurses who take mental cases only. Taking into consideration the general good health of the community and the inability of many to afford the services of a private nurse, the result of the year's working is regarded as satisfactory. The gross receipts from patients amounted to £51,436, of which the sum of £48,403 has been paid to nurses. The income derived from commission on fees earned by nurses amounted to £3110. The address of the Co-operation is 22, Langham-street, London, W. 1.

LONDON TEMPERANCE HOSPITAL.—The annual report for 1922 contains a statement by the Medical Committee indicating the value of Erlangen deep-therapy for the treatment of cancer and other forms of malignancy. Illustrative cases are given. Among non-malignant conditions which have reacted favourably are fibroid tumour of the uterus, Hodgkin's disease, and keloid, while in lupus the treatment does not seem to have yielded better results than those obtained by ordinary X ray treatment. In the in-patient department 377 patients stayed an average of 19 days each, and one death occurred during the year. In 1921 the number of cases was 212, and the average stay 32 days; 6933 cases were seen in the out-patient department, as compared with 7719 in 1921. The total ordinary income was £7822 and the expenditure £8903.

DENTAL TREATMENT FOR INSURED PERSONS.—At a recent meeting of the Aberdeen Burgh Insurance Committee the following resolution, submitted by the Finance and Medical Benefit Subcommittee, was approved: In view of the fact that the benefits of deposit contributors under the National Insurance Acts are dependent upon the amount standing to their individual credits in the deposit contributors' fund, and that in very many cases there are substantial surpluses available for supplementary purposes, the Aberdeen Burgh Insurance Committee are of opinion that dental and ophthalmic treatment should be added to the benefits at present at the disposal of contributors, and recommend that steps should be taken to obtain legislative authority for the inclusion of such treatment amongst ordinary benefits under the Acts. It was agreed to forward a copy of the resolution to the Scottish Board of Health.

ASSOCIATION OF PUBLIC VACCINATORS.—The annual dinner of this Association was held at the Hotel Cecil on April 27th, with Dr. F. W. Brookes, the retiring President, in the chair. In proposing the toast of the Association, Dr. A. E. Cope referred to the aims of the Association which were still unattained after 25 years' work, inasmuch as the public vaccinators were still in the service of boards of guardians. The dwindling membership, now only a little more than a tenth of that possible, made the further pressing of their claims a matter of difficulty. Dr. Arthur Drury proposed the health of the visitors, and Dr. J. C. McVail and Dr. S. Monckton Copeman replied. Dr. McVail impressed on the members the inadvisability of entering into correspondence with anti-vaccinists in the public press unless armed with all the facts. Small outbreaks of small-pox had in the past and probably would continue to be the decisive factor in inducing people to be vaccinated. Dr. Copeman told several amusing stories of his work at the Ministry of Health in connexion with public vaccination. The health of the President was proposed by Dr. Climson Greenwood, first president of the Association.

Prof. George R. Murray, D.L., M.D., has been appointed to represent the Victoria University of Manchester at the ceremonies connected with the centenary of the birth of Pasteur, which will be held in Paris and in Strasbourg in May.

LONDON (R.F.H.) SCHOOL OF MEDICINE FOR WOMEN.—Princess Mary has consented to present the prizes and certificates to the students on Saturday, June 2nd. Scholarships to the total value of £1010 will be awarded for the session beginning in October next.

SMALL-POX.—No new cases have been reported at Nelson for over a fortnight. In all 64 patients have been treated, and of these 22 have been discharged. At Liverpool two cases of small-pox were discovered on board a liner from a South American port.

NATIONAL COUNCIL FOR MENTAL HYGIENE.—This Council was incorporated under the Companies Acts on April 5th. Subscriptions may be forwarded to the acting secretary, Room 55, Windsor House, Victoria-street, London, S.W. 1.

METROPOLITAN POLICE SURGEONS' ASSOCIATION.—The annual meeting and dinner of the Association were held at the Holborn Restaurant on April 26th, Dr. A. E. Kennedy, the retiring President, being in the chair. Amongst those present were the Rt. Hon. W. C. Bridgeman, M.P., Home Secretary; Sir Charles Ballance, chief surgeon to the Metropolitan Police; Sir Bernard Spilsbury; Dr. Cassidy, physician to the Metropolitan Police; and Dr. Sanders, M.O.H. for West Ham. An enjoyable musical programme was given after dinner.

PEOPLE'S LEAGUE OF HEALTH.—An oral examination in connexion with the recent series of the Sims Woodhead Constructive Educational Health Lectures, delivered to teachers under the auspices of the People's League of Health, was held on May 2nd at Hamilton House, Mabledon-place, London. A travelling scholarship prize, consisting of a week's visit to a foreign country, with facilities for visiting the health centres, will be awarded to the student obtaining the highest number of marks at this examination, and certificates will be awarded to others. The examiners were Prof. J. G. Adami, Prof. H. R. Kenwood, and Dr. Eric Pritchard.

DONATIONS AND BEQUESTS.—The late Mr. Joseph Howard, J.P., left by will £1000 to the Prince of Wales's General Hospital, Tottenham, and £500 each to the Passmore Edwards Hospital, Wood Green, N., and Dr. Barnardo's Homes.—Under the terms of the will of the late Mr. H. Kaye, of S. Croydon, who shot himself after shooting his wife and child in September last, the hospitals of London will benefit at the discretion of the trustees. The testator left property to the value of some £85,000.—Sir Charles Brown, chairman of the Harris Orphanage, Fulwood, has given £800 to complete the purchase of a house at Lytham as a seaside home for sick and convalescent children of the orphanage.—Mr. Louis Walker, of Bradford, and a former member of the Sanitary Committee, bequeathed £2000 to the Bradford Royal Infirmary and £2000 to the Royal Albert Asylum, Lancaster; £1000 each to the Bradford Institution for the Blind and the Bradford Eye and Ear Hospital; and £500 to the Bradford Children's Hospital.—During last month the St. Mary's Hospitals, Manchester, received legacies and donations amounting to £256, and the Manchester Royal Infirmary £1425.

NOTES ON CURRENT TOPICS.

Registration of Medical Herbalists.

THE text of the Bill introduced into the House of Commons by Lieut.-Commander KENWORTHY to provide for the registration of medical herbalists has now been issued. Clause 1 deals with the establishment and constitution of a general medical herbalists council composed of nine members appointed by the Privy Council, the Minister of Health, the Board of Education, as well as the President, the Vice-President, and the members of the Council of the National Association of Medical Herbalists of Great Britain, Limited. Each member of the Council other than the first members is to hold office for five years. Clause 2 provides for the keeping of a register of medical herbalists who satisfy certain conditions of admission. Clause 3 provides for the making of rules by the General Medical Herbalists Council, such rules to be subject to the approval of the Minister of Health. Clause 4 deals with the staff and expenses of the Council, and Clause 5 prescribes the conditions under which fees are to be charged for registration. In Clause 6 provision is made for the admission under certain conditions of persons trained outside the United Kingdom. Penalties are imposed for the unauthorised use after the passing of the Act of the name or title of registered medical herbalist, the improper use of certificates of registration and falsification in any matter relating to the register. The Bill does not apply to Scotland or Ireland.

HOUSE OF LORDS.

WEDNESDAY, APRIL 25TH.

Dangerous Drugs Bill.

ON the motion of the Earl of ONSLOW the Dangerous Drugs and Poisons Amendment Bill was read a second time.

HOUSE OF COMMONS.

TUESDAY, APRIL 24TH.

The Housing Bill.

MR. NEVILLE CHAMBERLAIN (Minister of Health), in moving the second reading of the Government's new Housing Bill, said that the building of houses had not overcome the problem of overcrowding. This state of affairs he admitted constituted a perpetual danger to the physical and moral health of the community. But it was necessary to treat the problem with sense as well as with sensibility. It was necessary to begin the expansion of dwelling-houses upon lines which were capable of growth and development, and as far as possible artificial devices should be avoided. Private enterprise in housing was beginning to function once more. He was rather surprised to find how many houses had been built without any assistance from the State or local authorities. During the past six months upwards of 12,000 houses had been completed, and another 16,000 were in course of erection. The clause on slum areas in the Bill was not the last word on the subject, but it would enable them to get a considerable amount of work done in the next few years. The Government contemplated that the annual loss on houses built under the Bill would be approximately double the equivalent of the £6 subsidy which the State was providing, and the extra loss would have to be borne by the local authorities out of the rates. They were reversing the Addison plan in the interests of economy. The dimensions of the subsidy houses would be 810 superficial feet.

MR. WHEATLEY, on behalf of the Labour party, moved a resolution to the effect "That this House cannot assent to the second reading of a Bill which is inadequate to deal with the present housing shortage; ignores the difficulty of land purchase and transfer; fails to provide the means of securing a sufficient supply of building materials at reasonable prices; throws an excessive financial burden upon local authorities, and interferes unnecessarily with their administrative powers; fails to reduce the burden of interest imposed upon dwelling houses by the present financial system; and provides only for an unreasonably small type of house." The proposed houses, he said, were too small, miserably small. They would never be homes; they would soon be slums.

MR. R. J. DAVIES seconded the motion for rejection. On the debate being resumed on the following day, Lieut.-Colonel FREMANTLE said he would like to make a few remarks from the point of view of one who had essentially studied the question of housing for 20 years, for 15 of them as a medical officer of health, and more latterly in an administrative capacity in connexion with the London County Council. If they did not force the pace he believed

that they would get a good output of houses under the new scheme. As a medical man who was most anxious to help to prevent the evils arising from bad housing and anxious to remedy them so far as possible, he made an appeal that all the available machinery should be utilised, and he asked Members on both sides of the House to stimulate all the different circles in the community on which they had any influence, and to coöperate in seeing that both private enterprise and public machinery were employed in the solution of the housing problem during the next few years.

On a division the amendment was defeated and the Bill was read a second time by 340 votes to 140.

WEDNESDAY, APRIL 25TH.

Women Physicians as Panel Doctors.

MR. BURGESS asked the Minister of Health how many women physicians were at present acting as panel doctors.—MR. NEVILLE CHAMBERLAIN replied: The total number of women medical practitioners engaged in insurance work in England and Wales is 215.

Cost of the Board of Control.

MR. AMMON asked the Minister of Health whether he would furnish a return of the cost of the Board of Control for the year 1922, including salaries, expenditure of office staff, and travelling expenses.—MR. NEVILLE CHAMBERLAIN replied: The total gross cost of the Board of Control for the financial year 1922-23 was approximately £470,236, less appropriations in aid (fees for licences, &c.) £7756. The gross cost includes grants in aid to local authorities and voluntary institutions £408,791, cost of State institutions for mental defectives £26,795, salaries and expenses, &c., of head office staff £34,650.

Leprosy in Great Britain.

COL. SIR CHARLES YATE asked the Minister of Health whether, considering the marked improvement in the condition of lepers that had been obtained as the result of treatment and research in the leper asylums in India, he would consider the question of taking steps to ascertain how many cases of leprosy there were in this country and what success had attended their remedial treatment.—MR. NEVILLE CHAMBERLAIN replied: The treatment and research referred to are being carefully studied in my department, and I understand that they will be fully discussed at the forthcoming International Conference on Leprosy at Strasbourg, at which this country will be represented by one of the medical officers of the Ministry. I am advised that information is already available as to the approximate number of cases of leprosy in this country and that the treatment referred to in the first part of the question is being used in some of these cases.

THURSDAY, APRIL 26TH.

Codification of Law Relating to Coroners.

MR. WARNE asked the Secretary of State for the Home Department if he was aware that the Departmental Committee on Coroners' Law reported in 1909 that the present law of death certification offered every opportunity for premature burial and every facility for the concealment of crime, and that a great deal of the law relating to coroners dated from the thirteenth century and was not well suited to the changed conditions of modern life; and, in the presence of these statements and the fact that laws relating to coroners were comprised in about 30 Acts of Parliament, what steps was he taking to codify the law on this important subject.—MR. LOCKER-LAMPSON replied: A Bill to consolidate and amend the law relating to coroners is in course of preparation, but my right hon. friend cannot say when it will be possible to introduce it.

MONDAY, APRIL 30TH.

Appointments in Colonial Medical Service.

LIEUT.-COLONEL FREMANTLE asked the Under-Secretary of State for the Colonies which colonies, and how many individual medical appointments, were affected by the discontinuance of recruitment in this country in the case of certain medical posts at low salaries; how these appointments were now filled by the several colonies; and what were the medical qualifications and nationality of the successful candidates for such posts.—MR. ORMSBY-GORE replied: The question whether a medical appointment in the West Indies should be filled from this country is frequently decided only when a vacancy occurs, and accordingly it is not possible to state definitely how many individual appointments are affected, but the number is probably between a dozen and a score. The appointments concerned are some of those in the Windward, Leeward, Bahamas, Turks, Caicos, and Cayman Islands. Most of them are filled by local West Indian candidates of British nationality possessing qualifications obtained in the United Kingdom or Canada. It appears that there are only two medical men in the islands in question whose qualifications are foreign.

Colonel FREMANTLE asked if it was not the case that recent appointments had been given to men with American degrees because the conditions of service were not such as to attract those of British nationality?—Mr. ORMSBY-GORE said he believed that these two exceptions with American degrees were British West Indians.

Colonel FREMANTLE asked the Under-Secretary of State for the Colonies whether the Secretary of State for the Colonies was still, in the words of the Wood Report, always hampered in recruitment for colonial medical appointments carrying rights of private practice by the absence of sufficient data as to the value of such practice; if so, what steps had been taken by his department to give effect to the suggestions of his predecessor in office for removing this defect; and with what result.—Mr. ORMSBY-GORE replied: My hon. and gallant friend will no doubt appreciate that the value of a private practice must vary in accordance with the individual capacity of its holder, and accordingly such information as the Colonial Governments are able to supply can only be of limited utility as a guide to the value of the appointment. The passage in the report dealing with this point was referred to the Colonial Governments concerned for their observations and no specific reply has yet been received. I may say, however, that there has been no difficulty in the case of any appointment to these Colonies since the date of the report.

Colonel FREMANTLE: Is it a fact that despite these uncertainties to which the Under-Secretary has referred a definite idea of the enormous advantages of the private practice is given to those who are applying for these appointments?—Mr. ORMSBY-GORE: I believe the candidate is told in round figures what the private practice brought in to the previous occupant of the post.

TUESDAY, MAY 1ST.

Retirement of R.A.M.C. Officers.

Colonel Sir ARTHUR HOLBROOK asked the Under-Secretary for War whether, seeing the slowness of promotion now existing, he would explain why lieutenant-colonels of the Royal Army Medical Corps and the Royal Army Veterinary Corps were not obliged to retire after four years' service in that rank, as was the case in the infantry, artillery, and other branches of the army.—Lieut.-Colonel GUINNESS replied: No fair comparison can be made with the combatant branches, where conditions are different. The combatant officers in question are not retired, and the fact that they go on half pay does not deprive them as a class of adequate opportunities of further employment. No opportunities on a similar scale would be available for the departmental branches.

Women Medical Inspectors of Prisons.

Mr. BRIANT asked the Secretary for the Home Department if there were any women inspectors of prisons, women medical inspectors of prisons, and women commissioners of prisons; and, in view of the very large number of women in various penal institutions, if he would make appointments of persons of their own sex to these positions.—Mr. BRIDGEMAN replied: There are no women holding the appointments referred to. A woman has been appointed Governor of Aylesbury Borstal Institution, many women magistrates serve on the visiting committees of local prisons, and many women act as unofficial visitors to the women, 1078 in number, in prisons and similar institutions.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETINGS OF SECTIONS.

Monday, May 7th.

TROPICAL DISEASES AND PARASITOLOGY: at 8.30 P.M.

Annual General Meeting:

Election of Officers and Council for 1923-24.

Paper:

Lieut.-Colonel A. E. Hamerton: The Establishment of an Anti-rabic Institute in the Tropics.

Tuesday, May 8th.

PSYCHIATRY: at 5.30 P.M.

Annual General Meeting:

Election of Officers and Council for 1923-24.

Wednesday, May 9th.

SURGERY: SUBSECTION OF PROCTOLOGY: at 5.30 P.M.

Annual General Meeting:

Election of Officers and Council for 1923-24.

Discussion on Ulcerative Colitis.

The following have promised to take part in the Discussion: Sir Humphry Rolleston, Sir Thomas Horder, Mr. W. Ernest Miles, Mr. P. Lockhart-Mummery, Prof. L. S. Dudgeon, Dr. W. E. Carnegie Dickson, and Dr. A. F. Hurst.

Members of the Subsection and others desiring to speak are requested to communicate with the Hon. Secretary, Mr. Percival Cole, 15, Harley-street, W. 1.

MEDICINE, SURGERY, PATHOLOGY.

Members of these Sections are cordially invited to attend and to take part in the above Discussion.

The Annual Dinner of the Subsection will be held on Wednesday, May 9th, at Oddenino's Restaurant, at 8 for 8.15 P.M. The price of the Dinner is 12s. 6d. (exclusive of wine) payable at the table.

Members intending to be present are requested to notify Mr. Percival Cole, Hon. Secretary.

Thursday, May 10th.

NEUROLOGY: at 5 P.M.

Annual General Meeting:

Election of Officers and Council for 1923-24.

To be followed by a Clinical Meeting.

The Annual Dinner of the Section will be held at the Langham Hotel, Portland-place, W., at 7.30 P.M.

Friday, May 11th.

CLINICAL: at 5.30 P.M.

Annual General Meeting.

Election of Officers and Council for 1923-24.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, London, W.C.

WEDNESDAY, May 9th.—5 P.M., Prof. Geoffrey Keynes:

Hunterian Lecture on Chronic Mastitis.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C. 1.

POST-GRADUATE COURSE: MAY-JUNE, 1923.

CLINICAL LECTURES AND DEMONSTRATIONS.

MONDAY, May 7th.—2 P.M., Out-patient Clinic: Dr. Hinds Howell. 3.30 P.M., The Syndrome of the Corpus Striatum: Dr. Kinnier Wilson.

TUESDAY, May 8th.—2 P.M., Out-patient Clinic: Dr. Grainger Stewart. 3.30 P.M., Cerebellar Disease: Dr. Risien Russell.

THURSDAY, May 10th.—2 P.M., Out-patient Clinic: Dr. Kinnier Wilson. 3.30 P.M., Disorders of Sensation and Their Significance: Dr. Walshe.

FRIDAY, May 11th.—2 P.M., Out-patient Clinic: Dr. Gordon Holmes. 3.30 P.M., Treatment of Cerebral Tumour: Mr. Sargent.

COURSE OF LECTURES ON NEURO-PATHOLOGY.

MONDAY, May 7th.—12 noon, Cerebro-spinal Fluid: Dr. J. Godwin Greenfield.

A COURSE OF 12 LECTURES ON THE ANATOMY AND PHYSIOLOGY OF THE NERVOUS SYSTEM will be given at 12 noon on TUESDAYS and FRIDAYS if there are sufficient entries for it.

Mr. Armour and Mr. Sargent operate at the Hospital on Tuesday and Friday mornings at 9 A.M., or at such other times as may be announced.

The fee for the whole Course is £12 12s., including Anatomy and Physiology; but these Lectures may be taken separately for a fee of £4 4s. The fee for the Course without Anatomy and Physiology Lectures is £10 10s. Special arrangements as to fees will be made for those unable to take the whole Course. Fees should be paid to the Secretary of the Hospital at the office on entering for the Course.

C. M. HINDS HOWELL, Dean of Medical School.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY, May 7th.—10 A.M., Mr. MacDonald: Genito-Urinary Operations. 12 noon, Mr. Simmonds: Applied Anatomy. 3 P.M., Mr. Simson: Diseases of Women.

TUESDAY.—10.30 A.M., Dr. Paterson: Demonstration of Cases (Medical Wards). 2 P.M., Mr. Banks-Davis: Diseases of Throat, Nose, and Ear. 2.30 P.M., Mr. Tyrrell Gray: Surgical Wards.

WEDNESDAY.—11 A.M., Mr. Simson: Gynaecological Demonstration. 12.15 P.M., Dr. Burnford: Medical Pathology. 3 P.M., Dr. Pernet: Skin Department.

THURSDAY.—12 noon, Mr. Simmonds: Demonstration of Fractures. 2 P.M., Mr. Bishop Harman: Eye Department. 2 P.M., Mr. MacDonald: Genito-Urinary Department.

FRIDAY.—10 A.M., Mr. Dudley Buxton: Dental Department. 11 A.M., Dr. MacDougall: Electrical Department. 2 P.M., Dr. Burrell: Medical Out-patients.

SATURDAY.—9.30 A.M., Dr. Burnford: Bacterial Therapy. 10 A.M., Dr. Saunders: Medical Diseases of Children. 10 A.M., Mr. Banks-Davis: Operations on Nose, Throat, and Ear.

Daily, 10 A.M. to 6 P.M., Saturdays 10 A.M. to 1 P.M.; In-patients, Out-patients, Operations, Special Departments.

NORTH-EAST LONDON POST-GRADUATE COLLEGE,
 Prince of Wales's General Hospital, Tottenham, N.
 Demonstration of Clinical Cases at 3.30 P.M.
MONDAY, May 7th.—Mr. J. Bright Banister: Gynaecological.
TUESDAY, Dr. J. Metcalfe: Radiological.
WEDNESDAY.—Mr. C. H. Hayton: Throat and Nose.
THURSDAY.—Dr. Yealland: Medical.
FRIDAY.—Mr. E. Gillespie: Surgical.

LONDON HOSPITAL MEDICAL COLLEGE, Mile End, E.
TUESDAY, May 8th.—5.15 P.M., Dr. Millais Culpin: The Unconscious.
FRIDAY.—5.15 P.M.: The Dynamics of the Unconscious.

INSTITUTE OF PATHOLOGY AND RESEARCH, St. Mary's Hospital, Paddington, W.
THURSDAY, May 10th.—4.30 P.M., Dr. H. H. Dale: The Physiology of Insulin.

LONDON SCHOOL OF MEDICINE FOR WOMEN, 8, Hunter-street, W.
TUESDAY, May 8th.—5 P.M., Prof. A. L. McIlroy: Obstruction to Labour.

NATIONAL HOSPITAL FOR DISEASES OF THE HEART, Westminster-street, Marylebone, W. 1.
THURSDAY, May 10th.—5.30 P.M., Dr. F. W. Price: The Clinical Investigation of Tachycardia.

LONDON LOCK HOSPITAL, 91, Dean-street, W. 1.
TUESDAY, May 8th.—2.30 P.M., Mr. J. E. R. McDonagh: Treatment of Gonorrhoea and its Complications.
WEDNESDAY.—5 P.M., Mr. F. Juler: The Commoner External Venereal Diseases of the Eye.
THURSDAY.—4.30 P.M., Mr. Lawrence Abel: Treatment of Acute Gonorrhoea in the Male.
FRIDAY.—4 P.M., Mr. Johnston Abraham: Treatment of Gonorrhoea in the Female.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone-road, N.W.
THURSDAY, May 10th.—5 P.M., Dr. C. H. Roberts: The Badly Flexed Head.

INFANTS HOSPITAL, Vincent-square, S.W. 1.
MONDAY, May 7th.—6 P.M., Dr. Eric Pritchard: Modification of Milk.
THURSDAY.—6 P.M., Modification of Dried Milk.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE LECTURES.
TUESDAY, May 8th.—4.15 P.M., Dr. G. R. Murray: Organotherapy.

SALFORD ROYAL HOSPITAL.
THURSDAY, May 10th.—4.30 P.M., Dr. Gibson: Psoriasis.

UNIVERSITY OF BRISTOL POST-GRADUATE DEMONSTRATIONS (in the Medical Theatre).
THURSDAY, May 10th.—3.30 P.M., Dr. Carey Coombs: Present-day Methods of Examining Cases of Cardio-Vascular Disease.
FRIDAY (at Dorchester).—Mr. T. Carwardine: Diagnosis and Treatment of Gall-Bladder Diseases.

Appointments.

DALEY, F. G., M.A., B.M., B.C. Camb., D.P.H. Oxf., M.R.C.S., L.R.C.P. Lond., has been appointed Medical Officer of Health for the Metropolitan Borough of Wandsworth.
BARTON, W., L.R.C.P. Lond., M.R.C.S., D.M.R.E. Camb., Honorary Radiologist, St. Bartholomew's Hospital, Rochester.
COLLA, F. L., M.B., B.Ch. Oxf., F.R.C.P., Pathologist to the London County Mental Hospitals.
DEED HILL, K., M.D., B.S. Lond., Resident Surgical Officer to the Kent County Ophthalmic Hospital, Maidstone.
VENTFIELD, W., L.R.C.P. & S. Edin., L.F.P.S. Glasg., Certifying Surgeon under the Factory and Workshop Acts for the Walton-on-Naze District of the County of Essex.
Leicester Royal Infirmary: RIDLEY, N. C., M.B. Lond., F.R.C.S. Eng., Consulting Ophthalmic Surgeon; BARTON, M. H., F.R.C.S. Edin., Hon. Ophthalmic Surgeon.
Manchester Royal Infirmary: SUTHERLAND, D. McKAY, M.D., Ch.B. Manch., F.R.C.S. Eng., Resident Surgical Officer; BUCKLEY, G. H., M.B., Ch.B. Manch., Assistant Resident Surgical Officer; CUBITT, BARBARA, M.B., B.S. Lond., Resident Medical Officer (Central Branch); and HICKSON, S. K., M.B., Ch.B. Manch., Assistant Registrar, Electrocardiograph Department.
St. Mary's Hospitals, Manchester: KILROE, J. S., M.B., Ch.B. Manch., BEGG, E. C., M.B., Ch.B. Manch., and HULME, J. W., M.R.C.S., L.R.C.P. Lond., House Surgeons at the Whitworth-street West Hospital.

Vacancies.

Wilkesden General Hospital, Harlesden-road, N.W.—Hon. P.
Wolverhampton and Staffordshire General Hospital.—Res. Cas. S. £250.
 The Chief Inspector of Factories, Home Office, London, S.W., announces a vacant appointment at Burton Latimer (Northants).

Births, Marriages, and Deaths.

BIRTHS.

HANDFIELD-JONES.—On April 29th, at Ashworth-mansions, W., the wife of R. M. Handfield-Jones, M.C., M.S., F.R.C.S., of a son.
WOODWARK.—On April 27th, at 4, Harley-street, W., to Hilda, wife of A. S. Woodwark, C.M.G., C.B.E., M.D., F.R.C.P.—a son.
YEOMAN.—On April 29th, at 10, Duchy-road, Harrogate, to Dr. and Mrs. W. Yeoman—a son.

MARRIAGES.

BANKS—HOGG.—On April 25th, at St. George's, Hanover-square, Harry Banks, F.R.C.S., to Jessie, youngest daughter of the late Captain Hogg and Mrs. Hogg, Crouch-hill, London.
BOYCE—O'KINEALY.—On April 18th, at the British Consulate, Monte Carlo, Charles Boyce, M.D., to Winifred Mary O'Kinealy (widow of Capt. James O'Kinealy, R.A.), of Compton Cottage, Canford Cliffs, Dorset.
HILLMAN—MILLER.—On April 23rd, at Christ Church, Lancaster Gate, Oscar Stanley Hillman, M.B., F.R.C.S., to Ethel Florence Miller.
MACDONALD—PAUL.—On April 18th, at St. Luke's, Holloway, Donald Macdonald, M.A., M.B., to Emily Lever, only daughter of Mr. and Mrs. Alex. Paul, late of Bebington, Cheshire.
MULLIGAN—TAYLOR.—On April 25th, at Davos, Michael John Mulligan, M.B., D.P.H., to Lilian Ellen Veronica, only daughter of the late Mr. and Mrs. Charles Taylor, of Heswall, Cheshire.

DEATHS.

KILLICK.—On April 27th, at his residence, Spring Bank-place, Bradford, Charles Killick, M.D., F.R.C.S., aged 48.
MURPHY.—On April 27th, at Bentinck-terrace, London, N.W., of influenza and bronchitis, Lieut.-Colonel Sir Shirley Forster Murphy, K.B.E., F.R.C.S., aged 74 years.
N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

THE PREVENTION OF CONGENITAL SYPHILIS.*

By J. H. SEQUEIRA, M.D., F.R.C.P. LOND.,
F.R.C.S. ENG.,

PHYSICIAN TO THE SKIN DEPARTMENT AND LECTURER ON
DERMATOLOGY AT THE LONDON HOSPITAL, ETC.

THE problem of the prevention of congenital syphilis is one of the most important in medicine, and I think we may reasonably venture to congratulate ourselves on the progress made towards its solution in recent years, and also to hope for material improvement in the near future. By congenital syphilis I mean infection of the embryo by the *Spirochæta pallida* up to and including birth. I prefer the term "congenital syphilis" to "hereditary syphilis" or "heredo-syphilis." Heredity implies some quality of the germ or sperm-plasm which becomes manifest as the embryo develops. While I do not deny that some such influence may result from spirochætal infection of one or both parents, there is no evidence that the conditions now under consideration are produced except by the fortuitous introduction of living spirochætes into the embryo while in utero or in its passage through the genital canal during parturition.

Unlikelihood of Paternal Infection.

You will realise at once that I look upon congenital syphilis as due to maternal infection. I am aware that some high authorities, particularly those of a past generation, have maintained that paternal infection of the embryo without infection of the mother is possible, but all recent investigation tends to show that if such infection occurs it is so rare as to be a negligible factor in the problem presented to us. My reasons for dismissing "paternal syphilis" from the purview of this discussion are:—

1. The *Spirochæta pallida* in the spirillar stage in which we recognise it clinically is too large to be contained in the head of the spermatozoon.
2. Even if there be a spore stage of the organism it is difficult to believe that it could be contained in the sperm-cell without being lethal.
3. The blood of the mothers of definitely syphilitic children, examined soon after the birth and up to the sixth month, gives a positive reaction in 95 per cent., a percentage which closely approximates to that found in acquired syphilis in the secondary or generalised stage.
4. The fact that a woman may have syphilitic children by a first husband, and apparently healthy children by a second, is of no value as evidence of paternal syphilis in the absence of serological tests of mother and infants. We have had several instances of children with positive Wassermann reaction (W.R.) alternating with children with negative W.R. of the same parents.

Date of Infection.

The results of infection by *Spirochæta pallida* vary with the date at which the organism invades the embryo. When the embryo is attacked early it will early succumb. Syphilis is the cause of from 15 to 20 per cent. of all miscarriages and stillbirths. The later the infection the more chance the embryo has of surviving. On rare occasions a living infant may be born with evidence of congenital syphilis, but it is a remarkable fact that in the large majority of instances the child at birth appears to be quite healthy, and that the clinical manifestations of disease do not appear for from three weeks to two months, and, rarely, later. In a few instances a bullous eruption may appear a few days after birth, and in such cases the infant rarely survives. Late manifestation of congenital syphilis affects the eyes, ears, bones, viscera, and, occasionally, the skin and adjacent mucous membranes, and the nervous system. That infection may take place during parturition has long been held; Dr. Eardley Holland has seen a case of primary chancre in an abrasion produced by forceps, and Lomholt has published two cases occurring in maternity clinics in Denmark. How the fetus in such cases escaped infection while in utero affords an interesting problem in immunology.

Preventive Measures.

The prevention of congenital syphilis resolves itself into two parts—(1) prevention of infection of the mother, and (2) adequate treatment of the syphilised woman before or during pregnancy.

Prevention of Infection of the Mother.—1. Any measures, moral or medical, which prevent the spread of syphilitic

infection must of necessity diminish the amount of congenital syphilis. Those of us with a somewhat lengthy experience must have recognised the diminution of congenital syphilis in the clinics. This is not by any means due to a diminution in the amount of venereal infection generally, but to the fact that syphilis is recognised earlier and better treated. Moreover, in the more highly-educated classes the proportion of syphilis among married women is very low. With the spread of knowledge of the dire results of this infection men will not marry unless they are assured that there is no danger of transmitting the disease to a wife or offspring. Unfortunately, cases do occur, but in many of them the man has believed himself free from infection at the time of marriage, and in some instances his medical adviser has been to blame. In my experience it is quite common for the husband's infection to occur at a later date from post-marital irregular sexual intercourse. Such irregularities are not uncommon in all classes, often during the later months of the wife's pregnancy or during her lying-in. Hence, we find a healthy child or children, followed by a series of miscarriages or stillbirths, or the birth of infected living children. It is obvious that a man who has thus contracted disease must be treated at once and adequately, and must abstain from sexual relations until pronounced free from infection.

2. Adequate Treatment of the Syphilised Woman Before or During Pregnancy.—Here, at the outset, we are met with a great difficulty. Many women suffer from syphilis without any knowledge of the fact. The primary lesion on the genitalia is often inconspicuous and causes little or no discomfort. It may be on the cervix uteri and cause no clinical symptoms. There may be a complete absence of secondary manifestations, and yet she may have a series of miscarriages or stillbirths, or bear living children which show sooner or later evidence of grave spirochætal infection.

I do not purpose to enter into any discussion of this remarkable absence of evidence of disease, but I would once again point out that the blood of such a woman will in 19 cases out of 20 give a positive W.R. We can prevent a great deal of congenital syphilis by examining the blood of every woman who has had a miscarriage or stillbirth, and if the W.R. prove positive by carrying out anti-syphilitic treatment which should be continued during subsequent pregnancy. At the same time the husband should be induced to come up for a blood examination and in his case also adequate treatment should be insisted upon. We have had most gratifying results in a large number of cases dealt with in this way, and when the treatment has been properly carried out later pregnancies have resulted in the birth of healthy, non-syphilitic infants.

A further development on these lines has been the routine examination by the W.R. of all women attending the ante-natal clinic. But here I have to introduce a note of warning—of 700 primigravidae attending the London Hospital Ante-natal Clinic, 19 were found to give a positive W.R. In some of these there was other evidence of syphilis, and wherever possible the husband was induced to have his blood also examined. But the number is too small to be of practical value. We have, however, met with cases in which we have no doubt there was no syphilis. In one instance in particular the woman died and a very complete autopsy showed no evidence of syphilis in her or in the fetus. The father was serologically and clinically free from disease. The fact that occasionally a normal pregnant woman's blood may give a strongly positive W.R. is established. So far our figures are not large enough to make a strong statement of the proportion, but I believe it is not more than 1 per cent. This is confirmed by the experience of Fordyce and Rosen, who state that from 25 to 35 per cent. of the patients referred to the Vanderbilt Clinic by maternity hospitals because of a strongly positive reaction with cholesterinised antigen alone give a negative reaction with all methods when they report several weeks after delivery, and remain negative in repeated examinations. We have, therefore, decided that it will be wise not to give anti-syphilitic treatment to pregnant women who give a positive W.R. without any history of miscarriage, stillbirths, or syphilitic children, if there is no other evidence pointing to syphilitic infection. Such patients, of course, must be carefully watched during their pregnancy and the blood test should be repeated, and, wherever possible, the blood of the husband should be examined.

Conclusions.

Congenital syphilis can be prevented:—

1. By early and complete treatment of every case of acquired syphilis both in the male and female.
2. Marriage should be forbidden until a condition of non-infectivity has been attained. From experience I am of opinion that this obtains if a person has had adequate anti-syphilitic treatment, and is free from all clinical evidence, and whose blood has been negative for two years. Some observers would also include an examination of the

* Abstract of a lecture delivered at the Royal Institute of Public Health, March 14th, 1923.

cerebro-spinal fluid. There remain some cases where the patient has had antisyphilitic treatment over a long period and the blood persistently gives a positive W.R. In such cases there can be no certainty, and the risk, though possibly slight, must be explained to the patient.

3. It would be advisable to obtain a W.R. in every prospective mother, bearing in mind the special points mentioned above.

4. Every mother who has a positive W.R. and whose clinical history, or history of miscarriages, stillbirths, or of syphilitic children shows that she is syphilitic, should receive antisyphilitic treatment during each subsequent pregnancy. If the treatment is thorough such pregnancy will certainly result in the birth of a healthy child. I specially lay stress on each subsequent pregnancy, as I have known instances where a healthy child has been born as the result of treatment during one pregnancy, but that subsequently an infected child has been born owing to reliance being placed on the previous treatment.

5. Every infant born to a syphilitic parent should be examined by the W.R. at regular intervals up to the second year.

6. With the view of preventing the development of late congenital syphilis we are in the habit of examining as far as possible all the children of a syphilitic parent by the W.R., and have thus been able to discover a large number of cases in which disease has been latent and unrecognised.

PUBLIC HEALTH IN BOMBAY.¹

The population of Bombay at the census of 1911 numbered 979,445; according to the provisional figures for the 1921 census, taken on March 18th, the population was 1,172,953; in the health officer's report the statistical ratios had necessarily to be calculated on the basis of the 1911 enumeration, and these ratios must accordingly be understood as over-statements of ratios of births, deaths, and disease prevalence. The birth-rate in 1920 was 20.14 per 1000, as compared with 21.16 in 1919, and 21.51 in the quinquennium (1915-19); but on account of the large number of births unregistered (as shown by infants vaccinated), Dr. J. E. Sandilands, executive health officer, the author of the report for this year, considers that the correct rate should be 27.53 per 1000. As usual there were wide variations among the different races that compose the population of the city; for Hindus, who form the majority (684,502) the birth-rate was 19.48; varying from 4.98 among Jains and 8.81 among Brahmins to 58.74 in those of "Low Caste," and 100.08 among the small community of Lingaits. For Mussulmans and Negro Africans the ratio was practically the same (19.77). For Parsees it was 26.27, for Anglo-Indians 26.74, and for Indian Christians 23.64; for "Europeans" 14.04. All these birth-rates are lower than in the previous year, except for Lingaits, Parsees, Jews, and Europeans, which show a slight increase, and that for Anglo-Indians, which is exactly the same. A comparison of the ratios in the different sections of the city shows remarkable variations; while in Fort South and Market sections the ratios were only 9.24 and 7.58 per 1000, in Upper Colaba and Byculla they were 47.52 and 59.68. Dr. Sandilands, however, states that "these ratios cannot be of much value for purposes of comparison, owing to the uneven distribution of single and married women of fertile age, which accounts in some measure for the remarkable differences in the rates recorded." The variation is, however, certainly remarkable.

The General Death-rate.

The general death-rate was 46.80 per 1000; in the previous year it had been 70.04; in 1918, 59.61; and in the decennium 1910-19, 39.56; of the whole population 79 per cent. live in one-room tenements. Here, again, the ratios varied enormously; in the section called "Harbour, Docks, Railway, and Homeless" (with a population of 44,979) the mortality was 3.35 per 1000, practically the same as in the preceding quinquennium (3.86), while in Upper Colaba (population 1557) it was 84.13 (and 82.20 in the quinquennium); this ratio may possibly be explained by deaths in hospitals in this section, which should, of course, be debited to the dwelling of the patient, if the address is known. The infantile mortality (552 per 1000 live births) was less than that of 1919 (653), but higher than the decennial average (439); of the total 10,896 deaths under one year, 3873 were due to respiratory diseases, and 3549 to congenital debility and premature birth. A number of infants who die in the city are either not born there or not registered; for this reason the ratios in the case of Jains and Brahmins (3862 and 1014) are absurd, but "unfortunately other figures in the table, which are reliable, tend to show that the actual as well as the apparent infantile death-rate in Bombay must be one of the highest in the world." There are few poor among the

Parsees, and their standard of education is high, yet the infantile mortality was 199 per 1000 births. Among Europeans the ratio was 311. (For the 96 great towns in England and Wales, including London, the infantile mortality in 1920 was 85 per 1000 births, in the metropolis alone it was 75.) After making all allowances, Dr. Sandilands is of opinion that the ratio cannot be estimated at less than 400 per 1000 births. Naturally there is great variation in the incidence in the various sections in the city; thus, in Fort South the ratio was only 250 and in Walkeshwar 335.6, while in Byculla it was 725.7, in Mandvi 990.5, and in Market 995.6; the actual numbers in the last two sections were 344 and 228 respectively, but it is stated that the high ratios "must be taken as in some considerable measure due to the non-registration of births in the sections." Of the whole number of births 75.8 per cent. occurred in "families living alone in a single room or sharing it with others," and among these the mortality was 631.1 per 1000 births; this, however, is a considerable improvement on the 1919 ratio, which had been 831.3 per 1000 births. Much has been done to reduce this excessive mortality by house visiting to find out prospective mothers and give advice, attendance on confinements, and provision of necessaries and comforts; maternity homes, infant milk depôts, and infant welfare centres have been established. As many as 23,365 visits were paid by municipal nurses and 1252 confinements were attended by them.

Epidemic Diseases.

In regard to epidemic diseases, it is noteworthy that 1920 was the first year since 1896 during which there was no epidemic of plague; there were 347 attacks and 282 deaths, the mortality being 0.28 per 1000, as compared with 1.25 for the preceding quinquennium. In Middle and Lower Colaba section there were 30 fatal cases (1.52 per 1000, against 4.37 in the quinquennium); in no other section did the mortality exceed 0.60 per 1000 (except Parel, 0.63), and in Upper Colaba and Chowpati there were no fatal cases at all. Inoculation, rat destruction, evacuation, and disinfection were carried out systematically and with success. Small-pox caused 294 deaths, or 0.30 per 1000, compared with 0.79 in 1919 and 0.70 in the quinquennium; in Girgaum and Mahalakshmi sections the ratios were 0.87 and 0.76; in Upper Colaba, First Nagpada, and Sewri there was not a single death. Of the 48 infants who died from this disease, 40 were not vaccinated; the vaccinal condition of the remaining eight could not be ascertained. Of the 19,731 infants whose births were registered, only 57.64 per cent. were vaccinated. Of the 18,008 Mahomedan pilgrims who embarked for the Mecca pilgrimage, 16,909 were vaccinated before leaving Bombay. In 1919 there had been 9658 cases of cholera in the city, of which 8455 were fatal, giving a death-rate of 8.63 per 1000; the sections most affected had been Parel and Sewri, with ratios of 22.27 and 20.29 respectively. In 1920 the cases numbered only 195 (of which 145 were imported) and the deaths 119, the ratio per 1000 being 0.12, 72 of these occurred in Esplanade section (4.53 per 1000); in no other section did the ratio exceed 0.16 (Sion), and in 11 sections there was not a single death. No testimony could be more conclusive than these figures as to the efficiency of the public health service under most difficult circumstances. Influenza was prevalent throughout the year, and 1605 deaths (1.63 per 1000) were attributed to this cause; in 1919 the ratio had been 1.98, and in 1918 4.04. Tuberculosis caused 1841 deaths (1.87 per 1000), of which 1631 were due to phthisis; this was a considerable improvement on the preceding year (2.83), and on the decennial average (2.39); the highest ratios (9.62 and 8.34) were registered in Esplanade and Upper Colaba sections; the lowest (0.20) both in Sewri and in Harbour and Docks sections. Among Hindus generally the ratio was 1.61; among Mahomedans 2.83, and for Anglo-Indians 4.05. A tuberculosis sanatorium has been opened on Bhoiwada Hill at Parel, where 114 cases were under treatment, of whom 69 were discharged and 22 died. For ague and remittent fevers 3216 deaths were registered, and in addition 311 deaths from "malaria," under which heading other fevers may very likely have been included; the mortality ratios were 3.28 and 0.31 per 1000 respectively. For the quinquennium 1915-19 the corresponding ratios had been 3.02 and 0.23. For malaria, and ague, and remittent fevers collectively (3.59 per 1000), the death ratios in the Ward sections of the city varied from 1.44 in Fort South and in Chukla to 9.28 in Sion and 10.06 in Sewri; in regard to race, for Hindus generally the combined ratio was 4.01, for Mahomedans 3.57, for Parsees 1.01, for Anglo-Indians 0.23 per 1000. It is obvious that these wide variations in incidence depend on local conditions, and are not attributable to the climate. An investigation was carried out as to the condition of the spleen in children in various poor class houses and charitable institutions; 6614 children were examined, with the result that splenic enlargement was found in 4.41 per cent., the ratio varying from 0.79 per cent. in Chowpati section of Ward D to 12.47 per cent. in Worli section of Ward G.

¹ Administration Report of Municipal Commissioner, 1920-21. Health Officer's Report for 1920. Bombay Times Press. 1921.

Among 9442 boys attending municipal schools in the city who were examined, the ratio was found to be 4.23, and among 4549 girls 6.57 per cent. Almost all the cisterns in the city have been rendered mosquito-proof, but the covers provided are frequently left open.

Water-Supply and Housing.

There have been difficulties in regard to the water-supply of Bombay for some considerable time past; the quantity available from Tansa lake (some 50 miles north-east, near Atgaon station on the G.I.P. Ry.), and from Vehar lake (in Salsette Island, 25 miles north) has been found to be insufficient; to remedy this a third pipe line from Tansa lake is in course of construction. As to drainage, also, the sewers have been found incapable of carrying off the quantity of sewage during the rains; with increase of water-supply this difficulty will, of course, be aggravated. "These defects will be remedied when the construction of the new main sewer outfall has been completed." There are still 13,704 basket privies in use. Housing conditions are bad; "in the congested areas of the city houses four or even five storeys high will be found attached on either side and separated from a similar row of houses by a gully of less than 6 feet in width, which takes the overflow from privies." Steps have been taken to remedy this state of affairs; some 6000 tenements will shortly be under construction, and later on another 13,000 will be provided under the Worli scheme of the Improvement Trust. (Worli is on the west of the island some four miles north of Malabar Hill.)

Vaccination.

Dr. N. H. Choksy, reporting on the work of the Arthur-road Hospital, gives a very interesting and instructive table showing the influence of vaccination on the fatality of small-pox, compiled from the statistical records of 33 years. Among 6064 unvaccinated small-pox patients the case mortality was 35.7 per cent.; among 7413 patients who had been vaccinated the ratio was 14.5 per cent. During the last 12 years (1909-20) among the unvaccinated patients the case mortality varied from 26.6 per cent. in 1917 to 42.2 per cent. in 1909; in those vaccinated, from 10.0 per cent. in 1919 to 19.2 per cent. in 1914. Among 91 children under 10 years old admitted with small-pox in 1920, the case mortality in 54 unvaccinated was 35.2, among 37 vaccinated 5.4 per cent.

At the Maratha Plague Hospital there were only 123 admissions for plague, these being fewer than in any year since the outbreak of the disease in 1896; the case mortality was 64.2 per cent. Dr. Choksy obtained the best results with colloidal preparations of iodine; with this treatment in 260 cases the fatality was 59.9 per cent.

This report is fully illustrated with diagrams and tables; a sketch plan, showing the district areas of the city as at present existing, would be an acceptable addition.

BARTHOLOMEW FAIR.

In connexion with the celebration of the 800th anniversary of the founding of St. Bartholomew's Hospital, on June 5th-8th, there will be a revival, after nearly 100 years, of the great City Fair of London, Bartholomew Fair. The fair originated in the permission given to Rahere by Henry, King of the English, to hold a cloth fair to assist the erection and maintenance of the hospital he was building on the site where it now stands. The Hospital and the Priory Church drew a concourse of pilgrims to Smithfield, and through the crowds thus assembled the fair grew in strength and importance. The students of St. Bartholomew's Hospital to-day have selected the Tudor period as being the one which illustrates Bartholomew Fair at the zenith of its existence, and the revels, contests, and sports which characterised the fair at that period will be reproduced this year. The Lord Mayor of London will open the fair. Gifts for the fair will be welcomed, and should be addressed to the Matron, St. Bartholomew's Hospital, E.C. 1, and marked "Bartholomew Fair."

"PEG NICHOLSON'S KNIGHTS."

To the Editor of THE LANCET.

SIR,—Dr. Hingston Fox, in his interesting address to the Hunterian Society, reported in THE LANCET last week, refers to the fact that Sir William Blizard received his knighthood while he was first president of that society. May I add a note as to the circumstances under which Blizard received his honour?

The life of the King had been attempted by a mad woman, named Margaret Nicholson, who, with a knife in her hand, rushed at the King as he sat in his carriage. Arrested, the woman was sentenced to death by the Privy Council, but pardoned by the King and sent to a lunatic asylum where she lived several years. To congratulate the King upon his escape, every corporation of importance sent a deputation.

The head of each deputation was knighted. The Royal College of Surgeons sent its President, Mr. Blizard, who, by this means, received the accolade. Every gentleman so honoured became known as a "Peg Nicholson Knight."

May I add to this note a reference to the allusion you make to the handsome fee of 5000 guineas offered to Sir Andrew Clark by a patient who had gone to the Riviera. The gentleman, a man of great wealth, retained Sir Andrew Clark for a period of some six weeks and showed him the kindest hospitality. When the physician left, the patient offered him a fee of 5000 guineas. This Sir Andrew Clark declined on the ground that he had received so much comfortable hospitality during his stay. As he was leaving, however, the patient's wife put an envelope into his hand, saying, "As you would take nothing for coming to see my husband, give this to the London Hospital." The envelope contained a cheque for 5000 guineas.

I am, Sir, yours faithfully,

S. D. CLIPPINGDALE.

Malvern-road, Hornsey, N., April 30th, 1923.

HELLO, WEATHER PROGNOSIS!

DURING the present week an arrangement came into force by which the Post Office, in conjunction with the Air Ministry, communicates the daily weather reports to the telephone exchanges throughout the country. Any subscriber at the mere cost of a local call can now ring up his exchange after teatime and obtain a weather forecast for the following day. The Post Office hopes that the information may be of special benefit to farmers and other residents in rural areas. No doubt the accuracy of weather forecasts is greater when pooled over a sufficiently large area, but they have, we fear, hardly arrived at the stage of exactitude to determine a practitioner whether or not to take out his closed car or to determine a patient whether it is safe to leave umbrella and macintosh at home. Individual prognosis is difficult and can hardly be said yet to be completely solved whether for medicine or meteorology.

HEALTH POSTERS.

OUR contemporary, the *Guy's Hospital Gazette*, does not despair of posterizing the nation into health as a post-war occupation analogous to the posterizing into patriotism and posterizing into thrift of pre-war and war times. Substantial prizes are offered to be competed for by readers of the *Gazette*, for the best sentences suitable for a Health-First campaign. Mr. Frank Bryant, J.P., M.P., Colonel F. E. Fremantle, M.P., F.R.C.S., and Dr. Lauriston E. Shaw have consented to act as judges. The whole of the prize-money has been donated, and the surplus entrance fees, after allotting £13 (in certain contingencies) to augment the prizes, will be paid over as a contribution to the hospital. It is pleasant to find a competition to which no exception can be taken.

THE TREATMENT OF DISEASE ON COMMISSION.

A CORRESPONDENT, who is an analyst and consulting chemist, sends us the following letter (undated) which has just reached him:—

SIR,—I am enclosing you my booklet; it will give you some idea how I treat disease. My fee for consultation is £2 2s.; subsequent fees according to the number of visits. I am prepared to give you 25 per cent. commission on any patients you may send me—cash down as soon as received by me. When recommending clients, please give them your card that I may know by whom they are sent.

Thanking you in anticipation,

Yours faithfully,

J. LANGDON-LANGDON.

Diploma U.S.A., Physio-Medical Specialist.

Our correspondent had supposed that the "American Diploma" was a thing of the past. It appears not.

A GENERAL PRACTITIONER'S CARD INDEX.

WE have received from Messrs. H. K. Lewis and Co., Ltd., specimen cards and particulars of a card index system for book-keeping and case-taking which seems to constitute a simple and convenient means of dealing with these sides of a general practitioner's work. The book-keeping card combines day-book and ledger, and will last for one or several years, according to the number of entries made. A second card provides a morning and evening temperature chart, arranged for four weeks, based on the Rigden clinical chart. A third card holds case records, with space for recording number, name, age, sex, date, address, and occupation, and for notes of the case. The fourth card is a blank for continuations. A cabinet is supplied for holding the cards; the latter can be perforated for insertion in a holder to be carried on the day's round. Specimen cards with details of prices of cabinets and holders will be sent to any medical practitioner on application to Messrs. Lewis, at 136, Gower-street, London, W.C. 1.

A Discussion

ON

ULCERATIVE COLITIS.

Opening Paper at a Meeting of the Proctological Sub-section of the Royal Society of Medicine on May 9th

By SIR HUMPHRY ROLLESTON, K.C.B.,

M.D. CAMB., D.C.L., LL.D.,

PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON;
EMERITUS PHYSICIAN, ST. GEORGE'S HOSPITAL, LONDON.

THE subject of chronic ulcerative colitis, though mentioned in Wilks and Moxon's "Lectures on Pathological Anatomy" in 1875, owes its recognition in great measure to the writings of Sir William Hale-White, the President of this Society, who gave the first of his several descriptions of the condition in 1888. There was a discussion at the Section of Medicine of the Royal Society of Medicine in 1909, with statistics of 312 cases so diagnosed in the hospitals with teaching schools in London. In 1911 simultaneous discussions on colitis were held at the Harveian Society and at the Chelsea Clinical Society. It is a disease on which British physicians have made the great bulk of the contributions. The question naturally arises whether, in the years since these discussions, any important advance in our knowledge has been made. From the bacteriological and medical points of view it must be admitted that there is little to say. From the diagnostic standpoint the increasing appeal to the sigmoidoscope is important, and as regards treatment, the increasing stress laid on the value of appendicostomy is the most noticeable feature.

SCOPE OF THE TERM.

In introducing a discussion it is important to define its scope, and in this instance it is somewhat difficult to limit the field. By a process of exclusion, some idea may be arrived at; it will be agreed that many forms of ulceration of the colon may be eliminated as not coming within the meaning of ulcerative colitis. Thus exogenous ulceration due to an abscess rupturing into the bowel—e.g., an appendix abscess, malignant ulceration, stereoral ulceration, diverticulitis, typhoid and paratyphoid, "uræmic," and tuberculous ulceration, bacillary and amœbic dysentery—may be counted out. Ulceration due to acute colitis of known toxic origin, such as that due to corrosive sublimate poisoning, and the various forms of parasitic colitis and of infective proctitis of local origin and extent should not be included in ulcerative colitis. The ulceration exceptionally found in pneumonia and after accidents (those causing paraplegia having suggested a trophic disturbance) should also be excluded. A few words should be added about what was formerly known in this country as the ulcerative colitis of asylums and in America as institutional dysentery. Early in this century Vedder and Duval (1902) in America, and in this country Mott and Durham (1901) and Eyre (1904), showed that it was bacillary dysentery, thus confirming Gemmel's view (1898). Sir Frederick Mott has most kindly provided me with information as to the present position of knowledge of this disease in the London County Council Asylums; since the term "colitis" and the idea that it was a non-infectious disease due to trophic changes have been given up, the type of disease has altered so that severe and acute cases are less frequent. Outbreaks are almost certainly due to the presence of chronic carriers, and his assistant, Captain A. S. Mann, who has done much serological work on the subject, finds that the responsible organism is type X of the Oxford series of Flexner dysentery organisms. It appears advisable to exclude from the group of cases that may for convenience be called ulcerative colitis, the cases often arising in epidemic form in asylums, and to confine our attention to the sporadic cases seen in the ordinary

civil practice which are not, from a laboratory point of investigation, bacillary dysentery.

Bacteriologically ulcerative colitis is not a specific disease, for numerous organisms, *B. coli*, coliform organisms, *B. pyocyaneus*, pneumococci, and streptococci may appear to be the predominating and causal agents. A bacteriological diagnosis is comparatively easy in the acute stage, difficult when the condition has become chronic. The opportunities for secondary infection in the colon are most favourable, and it is probable that ulceration of the colon, originally due to one micro-organism, may be kept up by the combined attack of different bacteria, or to successive varieties or strains of pyogenic cocci. Lockhart-Mummery in 1911 drew attention to the gravity of cases of ulcerative colitis following tropical dysentery in which the original infection has died out. It is indeed difficult to be certain that the original infection has entirely disappeared; for although the stools may not give any evidence of amœbic or bacillary dysentery, the organism may still be present in the walls of the colon. Dr. J. W. McNee has shown me a specimen of the colon with *Entamoeba histolytica* in the blood-vessels from a man who had never been out of England and presented the symptoms of ulcerative colitis with absence of *E. histolytica* from the stools. It is not surprising that in such cases specific treatment, for example, emetine for latent amœbiasis, may fail to be curative, just as iodides may prove disappointing in an actinomycotic lesion with secondary streptococcal invasion. Further, ulceration of the colon is often a stage in an acute or chronic inflammation of the bowel, and not, as far as is known, a process due to the advent of a special micro-organism. The acute phase, as in hæmorrhagic colitis, may pass off or prove fatal before ulceration is established (vide Grant). It must indeed be admitted that ulcerative colitis is not a disease in the strict sense of the word, any more than rhinitis or bronchitis is, but that it is a syndrome with fairly constant clinical manifestations and anatomical changes, which may be excited by different factors.

ÆTIOLOGY.

As the causes favouring infection of the colon and widespread ulceration are obscure, reference may be made to McCarrison's and Findlay's observations showing that a devitaminised diet renders animals less resistant to infection; thus, McCarrison found that healthy monkeys, carriers of *Entamoeba histolytica*, may, as the result of a deficient diet, develop amœbic dysentery, and in an infected area organisms of the hog cholera group attack pigeons on a devitaminised diet and spare those properly fed. Diminution or deprivation of the water-soluble vitamin B, such as occurs in food consisting of excess of starch and fats, favours infection. The whole alimentary tract of the experimental animals shows atrophy and necrosis; and acute colitis but not ulcerative colitis was described. It is, however, easy to understand that in man a diet deficient in protein and water-soluble vitamin B might so reduce the healthy resistance of the mucous membrane of the colon that micro-organisms previously harmless, such as *B. coli*, would become pathogenic; in short, the carrier would become a patient. It is also conceivable that changes in the mucous membrane of the colon may so alter their environment that bacteria unable to multiply in ordinary conditions would grow without inhibition, in other words, that the intestinal flora would change. Bassler speaks of a coliform organism of enhanced virulence as the *B. pseudodysentericus coli*. Nearly 30 years ago the late Leopold Hudson suggested that swine fever and ulcerative colitis might be identical, and quoted a few instances in which the disease had followed the consumption of pork. He pointed out similarities between the morbid lesions and the clinical manifestations in the two diseases. Prof. F. Hobday tells me that no definite proof has as yet been brought forward in support of any connexion between these human and swine diseases.

COMPLICATIONS.

Is the incidence of perforation lower now than it was formerly in this country? Among 16 cases selected from those recorded in the *Transactions* of the Pathological Society of London (1885-1907) it occurred in five, and out of 33 fatal cases (probably including the above) collected in 1910 by Lockhart-Mummery, 9 showed perforation and general peritonitis; possibly some of the cases were published on this account; or has the type of the disease changed either from alteration in treatment or from less obvious causes? Among 22 selected cases of ulcerative colitis examined after death at St. George's Hospital between 1890 and 1922, Miss N. Schuster found four cases of perforation, two being in the "nineties" and two during the war; so far as this small group goes there does not appear to be any special alteration in the incidence of perforation. In very rare instances perforation is found after death with but little evidence of peritoneal response, and it is probable that the perforation was an agonal phenomenon when the reactive powers of the body were reduced to a minimum. In exceptional instances multiple perforations have been found. At the Mayo Clinic among 117 cases of chronic ulcerative colitis, which appear to have mainly followed dysentery, perforation was not uncommon and was a cause of localised abscess and not necessarily of general peritonitis. Hurst, on the other hand, found that localised abscess is exceptional and general peritonitis very rare, and that the latter when present is due to direct spread of infection through the walls of the colon and not to perforation. He states that stricture from cicatrization of the healing ulcers never occurs, and other experience in this country supports this conclusion; among the 16 selected cases from the Pathological Society there was one only in which any mention of narrowing is made; in that case the descending colon was described as much contracted and thickened; no stricture was found among the 22 cases analysed by Miss Schuster; Logan, however, definitely states that stricture is likely to occur. Possibly the nature of the Mayo Clinic cases are not exactly the same as those in this country. Arthritis, well recognised in bacillary dysentery, occurs in a small percentage of cases of ulcerative colitis. Among Yeoman's 65 cases arthritis or joint pains were noted in 4. Peripheral neuritis has also been noted. Ulceration in the small intestine is most exceptional.

CLINICAL FEATURES.

The sexes are equally affected, and the incidence falls chiefly on young adults and in early middle life; among Logan's 117 chronic cases 65 were under 30 years of age, and only 8 over 50. The onset may be sudden or insidious, and the course of the illness also acute or chronic. Acute colitis due to one micro-organism, such as the pneumococcus or streptococcus, or dysentery bacillus, may be succeeded by a chronic infection by a different bacterium. The first symptoms are usually those of colonic irritation—frequent stools, sometimes preceded by constipation. In the acute cases the temperature is raised; in chronic cases it is normal or even subnormal, except for elevations corresponding to exacerbations. The leucocyte count appears to vary; in some instances there is a leucocytosis, in others it is absent. As would appear probable (Price-Jones), on the assumption that there is a coliform infection, a lymphocytic increase has been reported (Horder, quoted by Hurst); but the blood picture would naturally differ with exacerbations and intermissions in the chronic form. Anæmia with 50 or even 20 per cent. of hæmoglobin is partly due to loss of blood, partly to toxins absorbed from the colon. The number of stools varies from 3 to over 20 in the 24 hours, but sometimes there are periods of constipation. The number of evacuations are less than in tropical dysentery, and tenesmus, which depends on the presence of ulceration low down in the rectum, inconstant; it occurred in one-third of Logan's cases. The excreta contain blood, pus, mucus, and sometimes sloughs of the mucous membrane. Onset with hæmorrhage has been correlated with the com-

mencement of ulceration low down in the colon (Hawkins). Abdominal discomfort is commoner than actual pain, the latter chiefly occurring before the bowels act or when there is much flatulence; local tenderness on deep pressure over the colon is variable. The importance of a sigmoidoscopic examination does not at the present day need emphasis; though it only provides information about part of the large intestine, that portion generally shows ulceration if it is present anywhere. The ulcers are indistinguishable from those of bacillary dysentery. Logan gives a number of skiagrams showing interference with the peristaltic waves which become lengthened, more superficial, with rounded instead of sharp edges, so that eventually the fibrosed colon appears as a thick-walled tube without haustrations, often with stenosis. Hurst describes mottling of the colon, which is often abnormally narrow from spasm. Appetite and digestion are fairly maintained, but loss of weight and weakness are induced by the diarrhoea and toxæmia. The mortality is high, about 50 per cent., and Lockhart-Mummery estimates that it reaches 78 per cent. when treated medically. The cases are prone to relapse. The chronic cases must be diagnosed from carcinoma, tuberculous and follicular ulceration of the colon, the sigmoidoscope being the obvious means of so doing.

TREATMENT.

Many methods of treatment have been employed.

Dietetic.—As the stomach and small intestine are practically always free from ulceration, and as digestion and absorption are fairly well carried on, it is unnecessary to restrict the diet to slops and soft food. As deficiency in the antiscorbutic vitamin C has been shown experimentally to reduce the resistance to infection (G. M. Findlay), and as McCarrison's observations suggest that lack of water-soluble vitamin B favours the incidence of inflammation of the alimentary canal, it would appear reasonable to arrange a diet containing a sufficiency of antiscorbutic food and a fair quantity of protein. Soured milk with living cultures of *B. bulgaricus* has naturally been given a trial, but Hurst did not find that it had any beneficial effect.

Drugs.—The large number of drugs employed is in itself a reproach to purely medical treatment. Intestinal antiseptics, such as salol, bismuth salicylate, β -naphthol, small doses of mercury or calomel, benzyl benzoate, gentian-violet, acriflavine, are on the whole disappointing. Pomegranate bark and simaruba have also been tried; and more recently of kaolin Logan remarks that it "was of no benefit whatever, although it is advised strongly by German writers." Finely powdered charcoal has been useful in reducing flatulence and obviating colic. Liquid paraffin by the mouth has been recommended as forming in the colon a coating in which bacteria cannot live (C. J. Macalister); and olive oil has been advocated both orally and by enemas (Logan). Lavage of the colon with antiseptics, such as boric acid, acetozone, argyrol, nitrate of silver, albargin (silver nucleinate), allantoin, emulsion of sulphur, has been much employed; but, as the whole of the colon cannot be thus satisfactorily cleaned, appendicostomy or cæcostomy has largely superseded rectal injections as an effective means of washing out the colon. Einhorn employs a "jointed intestinal tube" 15 to 20 ft. in length introduced by the mouth and carried, under the guidance of X rays, into the cæcum, where it is left in situ for days as a means of getting a result comparable to that of cæcostomy; this procedure is on its trial. The respective merits of appendicostomy and cæcostomy have been much discussed; when the appendix is obliterated or, for other reasons, cannot be found, a valvular cæcostomy can be made; but neither this procedure nor appendicostomy gives the colon the rest from the contact of faeces which an open cæcostomy or a colotomy does. In 1911 Sir D'Arcy Power took the cautious view that the improvement after appendicostomy was mainly due to the prevention of toxic absorption and keeping the bowel clean, and stated that the ulcerative

process continues until the patient becomes naturally or artificially (by means of vaccine) immune. Hurst considers that appendicostomy halves the time of illness that would be experienced under medical treatment, and surgical opinion is strongly in its favour. To give operation a fair chance it should be done before the patient is debilitated, and according to W. G. Spencer medical treatment should not be persisted in for more than three months. Short-circuiting the ileum into the pelvic colon has the serious drawback that the rectum is often affected; the radical means of providing physiological rest to the colon is a complete transverse ileostomy so as to exclude the colon; Stone recommends this in combination with a separate appendicostomy for irrigation of the colon.

Vaccines have been extensively employed; few reports are enthusiastic, and the difficulty of obtaining the causal organism is considerable, even with the help of serological reactions. An autogenous *B. coli* or coliform vaccine has usually been employed and should not be given during the acute exacerbations of this chronic infection, as the condition may thus be seriously aggravated. In 1909 H. P. Hawkins advocated anti-dysenteric serum, especially in acute cases, but without giving any statistics as to its value. In 1921 Hurst recorded very striking results from the intravenous injection of multivalent antidysenteric serum in two

patients who did not show dysenteric bacilli in their faeces. The healing of the ulcers as watched by the sigmoidoscope occurred in one of the cases in five days after the first injection of serum, and as the blood did not agglutinate any stock dysenteric organism, the question arises how far the curative action was due to the horse serum apart from its specific anti-dysenteric content.

THE TREATMENT OF LIVER ABSCESS BY ASPIRATION,

WITH AN ACCOUNT OF FIFTEEN CASES.

By PHILIP MANSON-BAHR, D.S.O., M.D. CAMB.,
F.R.C.P. LOND.,

GEORGE C. LOW, M.D. EDIN., M.R.C.P. LOND.,
PHYSICIANS, HOSPITAL FOR TROPICAL DISEASES, LONDON;
LECTURERS, LONDON SCHOOL OF TROPICAL MEDICINE;

J. J. PRATT, F.R.C.S. ENG.,
COL., I.M.S. (RET.); SURGEON, HOSPITAL FOR TROPICAL DISEASES;
LECTURER, LONDON SCHOOL OF TROPICAL MEDICINE;

AND

A. L. GREGG, M.D. DUB.,
SUPERINTENDENT, HOSPITAL FOR TROPICAL DISEASES.

AMOEBIIC abscess of the liver still ranks as one of the most dreaded of tropical diseases; until recently the open operation, as a means of evacuating the liver pus, dangerous and difficult though it may often be, has been universally considered the correct surgical procedure. Apart from risks attending the operation, the open method is apt to entail other consequences, such as a secondary bacterial infection of the sterile abscess cavity through the wound itself or through the drainage-tube, with ultimate sinus production or other unpleasant sequelæ. Even in the most practised hands the death-rate from the open operation must still be a pretty high one, though it has considerably diminished since anti-amœbic treatment has come to be regarded as a most necessary adjunct to surgical measures. The steps which have led to the more ready diagnosis of hepatic abscess, and consequently to a better understanding of its treatment, have recently been adequately reviewed by Rogers (1922).

Mortality from Hepatic Abscess.

It is difficult to procure exact figures bearing upon the mortality from the open operation, as, naturally, the risk to life varies under varying circumstances. The conditions under which the operation takes place naturally influence the result. European patients, for instance, stand a much better chance of recovery when subjected to operation in England than when exposed to the debilitating effects of a tropical climate. Then, again, in comparing figures due allowance must be made for native cases, for in them the mortality rate must be higher—applying, as they so often do, for treatment only when in extremis—

than in Europeans who usually seek medical advice directly symptoms manifest themselves.

According to Rogers, in the tables given in his "Bowel Diseases in the Tropics," the mortality in India and Mesopotamia from the open operation (native cases), even since the institution of anti-amœbic treatment, is still over 50 per cent. The death-rate, on the other hand, in a series of collected cases treated by the closed method—i.e., repeated aspiration—combined with medicinal treatment, is about 14.4 per cent. Other figures available read as follows: Tomes, in 1884, records a death-rate of 75 per cent. by the aspiration method and 31.6 per cent. by the open operation; in a large series of 300 cases, reported by Wildt in Cairo in 1904, the death-rate varied from 20-38 per cent.

Methods of Aspiring Liver Abscess.

The closed or aspiration method of evacuating liver pus is no new thing. As long ago as 1828 Annesley advised the evacuation of pointing hepatic abscesses by means of a trocar; in 1871 we find Maclean advocating the Bowditch syringe as a means of evacuating the fluid, but his outstanding contribution to this subject may be said to be his insistence upon the necessity of exhibiting large doses of ipecacuanha (20-25 gr. daily, or even more) in the treatment of the disease. His teaching had, however, been forgotten and has but recently been revived.

In 1879 Manson, in a private notebook, recorded a fatal case of hepatic abscess which he observed for over 60 days, and which he repeatedly tapped by means of a syringe, withdrawing over two pints of pus, but the cavity constantly refilled, so that he had to resort to continuous drainage. Failure in this case led him to devise (1883) the trocar and cannula which bears his name, and at this time we find him writing: "Not many years ago, to tell a patient he had abscess of the liver was nearly tantamount to telling him he was about to die. . . . But since the introduction of the aspirator, of the drainage-tube, and of Listerism, the prospects in this disease have enormously improved; at all events we need no longer stand by the patient with folded arms." He did not, however, realise at this time the necessity of exhibiting ipecacuanha at the same time as the operation. Others followed Manson's example, but eventually the practice seems to have fallen into disuse, possibly through lack of appreciation of Maclean's teaching.

Continuous aspiration or "tapping" was practised at this time by Veale (1882-3), and by Jessett (1885); the latter quotes one case which recovered after

16 tapplings in which a total of 400 oz. of pus was abstracted. In 1902 Rogers advocated repeated aspiration of hepatic abscess and injection of quinine in solution as an amebicidal agent, but was not at that time able to put his theories into practice; in 1906, together with Wilson, he recorded two successful cases treated by this method. In 1911 we find a more general adoption of aspiration in Calcutta, where 23 cases were recorded with four deaths, but we gather that re-accumulation of pus was also experienced, for nine cases had subsequently to submit to the major operation. Thurston, in 1914, critically analysed a series of 101 cases of liver abscess, and concluded that the routine exhibition of ipecacuanha or emetine in addition to aspiration reduced the death-rate from this disease considerably. Newman, writing at the same time, once more urged the importance of the open operation and free drainage, as being based upon sound surgical principles; aspiration, he insisted, was of use only in quiescent abscesses. Talbot, in 1919, recorded successful aspiration of 11 cases with no deaths in Mesopotamia during the war. The pus was drawn off by means of a 20 c.cm. syringe through the chest wall, but the importance of a thorough course of anti-amebic treatment as a complementary measure seems hardly to have been appreciated. Isolated cases treated by aspiration and emetine have been recorded in the literature by Rouget, Chauffard, Valence, and others.

Description of the Authors' Series of Cases.

In this paper we wish to describe a series of consecutive cases treated successfully in the last three years, during which period no other method of treating hepatic abscess has been adopted. Many of the cases were acutely ill on admission, yet there have been no deaths nor even supervention of any untoward symptoms following this simple operation. Moreover, we are satisfied that the method of aspiration, combined with medicinal treatment, adopted by us, presents many obvious advantages over the open exploratory method, which ranks certainly as a major operation.

Operation Technique.

1. An ordinary Potain's aspirator is sufficient. The needle should not be inserted to a depth exceeding $3\frac{1}{2}$ inches.
2. A reserve set of tubing and junctures in case of plugging with thick pus or blood-clot during operation is necessary.
3. When pus is struck by exploratory puncture, complete evacuation of the abscess cavity should at once be carried out as part of the same operative procedure.
4. Should the pus prove too thick for aspiration (Case 8), Manson's trocar and cannula can be inserted along the track of the aspiration needle, and a free evacuation of the abscess cavity thereby obtained.
5. *Site.*—No definite instructions can be laid down about the site of puncture; the site of election should be the point of greatest tenderness and swelling, should such exist. In the absence of any localising signs the routine procedure adopted by us has been (1) eighth interspace in anterior or mid-axillary line, (2) the epigastric route.
6. Without a general anaesthetic not more than three punctures at one time are advocated, but under general anaesthesia success has attended the search for pus after as many as six punctures.
7. Contrary to the usually accepted teaching, there appears to be no particular advantage in partial aspiration; in other words, as much pus as possible should be evacuated at one aspiration.
8. No special advantage seems to accrue from the injection of emetine or other amebicidal substances into the abscess cavity. Healing appears to take place without them.
9. The effusion of serum into the abscess cavity probably normally takes place and should be regarded as the natural method of repair. This must be con-

sidered as being quite a distinct process from a re-accumulation of pus (vide Case 2).

10. The risk of hæmorrhage after multiple punctures, although theoretically great, in practice appears to be of small import. Whenever possible, puncture of lung tissue should be avoided as increasing the risk of hæmorrhage.

The Choice of Anaesthetic.

1. In the great majority of cases general anaesthesia is to be preferred to local. When, however, definite localising signs are present and the position of the abscess is certain, or almost certain, or when the physical condition of the patient is such as to contraindicate the use of a general anaesthetic, then local anaesthesia can be resorted to, a 2 per cent. solution of novocaine with adrenalin being employed, and the skin and muscles (including the diaphragm, if necessary) must be infiltrated in the line of the puncture, but once the exploring needle has passed into the liver all risk of pain is over. *The passage of a stout needle through the liver substance is absolutely painless*; this was demonstrated in Case 3 when the abdomen was opened under local anaesthesia. But should this possibility not be suspected we have come to regard, as the result of our experience, a complaint of intense pain experienced by the patient during exploration under a local anaesthetic as not being suggestive of liver abscess, but as rather indicating the passage of the needle through some solid tumour, and in the latter contingency (malignant disease) we have noted that the small amount of blood withdrawn is also suggestive.

2. When, as the result of unsuccessful puncture, the possibility is suggested of the case proving to be one of malignant disease simulating abscess, then an exploratory laparotomy under general anaesthesia should be undertaken. Local anaesthesia possesses the advantage that, should the pus prove viscid and difficult of aspiration, continuous suction may be maintained for hours, if necessary, without causing any further discomfort or risk, such as would occur if prolonged general anaesthesia had to be kept up (see Case 3).

Details of Cases, with Remarks.

CASE 1.—B., 32, admitted on Jan. 17th, 1920, discharged Feb. 17th, 1920. Had amoebic dysentery in November, 1918; since then suffered from recurrent attacks of fever, pain in the right shoulder, persistent "dragging" epigastric pain, and, latterly, intermittent attacks of diarrhoea. On admission the temperature varied, sometimes up to 103° F.; the right hypochondrium was rigid, tender on pressure, and the liver definitely enlarged. Over the lower border of the liver the skin was raised and tense; the spleen just palpable. No *E. histolytica* cysts found. Hæmoglobin index 70 per cent.; red cells 3,300,000; leucocytes 22,000 (polymorphs 84 per cent.). On Jan. 27th, 1920, under general anaesthesia, the liver was punctured by means of Potain's aspirator in the anterior abdominal wall one inch to the right of the linea alba, an abscess was found, 20 oz. being withdrawn, and into the cavity 75 c.cm. of normal saline containing 3 gr. emetine were injected. The fever rapidly abated. Before discharge the patient had put on nearly 14 lb. in weight. Treated with emetine injections and with ipecacuanha powders, he has remained in good health ever since (1923).

A straightforward case in which the improvement following aspiration was immediate and permanent.

CASE 2.—M., 25, admitted March 8th, 1920, discharged May 15th, 1920. Dysentery in 1918, no recurrence; pain in liver January, 1920, involvement lower lobe of right lung with slight pyrexia. Slight leucocytosis (9000) (polymorphs 62 per cent.). Faeces negative for *E. histolytica*. March 23rd, 1920: liver aspirated in seventh intercostal space, 13 oz. of pus obtained and 3 gr. emetine in 10 c.cm. saline injected. Re-accumulation of pus necessitated second aspiration three weeks later, 19 oz. removed. On April 27th abscess formation suspected for third time, 6 oz. of clear serous fluid aspirated, no pus; medicinal treatment. 23 gr. of emetine with pulv. ipecac., gr. v.; convalescence uninterrupted; increase in weight 7 lb.

This case demonstrates that re-formation of pus in the abscess cavity should not be regarded as spelling failure of aspiration, for a second attempt may effectually remove the focus. The effusion of serum

into the abscess cavity which eventually took place may represent a normal method of cure; it was noted by Annesley in 1828.

CASE 3.—M., 39, admitted on June 9th, 1920, eventually discharged on Dec. 9th, 1920. Numerous recurrences of dysentery since November, 1918; pain in left side May, 1920. Definite dull, tender swelling in epigastrium extending to left hypochondrium, slight pyrexia, cyanosis, and great cardiac distress; leucocytosis 20,000. Faeces: active, *E. histolytica*. Under local anaesthesia (2 per cent. novocaine with adrenalin); aspirated in sixth left intercostal space, 43 oz. of thick pus (containing *E. histolytica*) obtained. Aspiration took two hours to complete. A second operation was undertaken a week later as the respiratory and cardiac symptoms persisted, the abdomen being opened under local infiltration anaesthesia. The liver was still enlarged and three further aspirations yielded 8 oz. blood-stained pus. A fortnight afterwards condition improved; pulmonary signs at left base diminishing. The Wassermann reaction being positive, he was discharged in order to obtain further injections of N.A.B. He was readmitted on Nov. 20th, 1920, for a full course of treatment with E.B.I., dysenteric symptoms having supervened. Since then there has been no recurrence either of hepatic or dysenteric symptoms, and he has put on over 14 lb. in weight.

This was evidently a left lobe abscess. On admission the general condition contra-indicated general anaesthesia. The removal of the first 43 oz. of pus by aspiration, by relieving the pressure, apparently saved the patient's life, who, at that time, would have succumbed to any major operation.

CASE 4.—G., 41, admitted on Nov. 12th, 1920, discharged on Dec. 20th, 1920. In July, 1920, noted a dull aching pain in his right shoulder, gradually spreading to the side of his chest, most intense along the anterior costal margin, and worst at night; sweats, cough, and loss of weight had followed. On admission he had severe hepatic pain, also irregular pyrexia (temp. 101° F.) with increased liver dullness. Red cells 3,700,000; leucocytes 8800 (polymorphs 75 per cent.); faeces contained cysts of *E. histolytica*; no visible ulceration of the rectum. On Nov. 16th, 1920, aspiration in epigastrium opposite eighth costochondral junction resulted in the withdrawal of 28 oz. liver pus; 3 gr. emetine in 10 c.cm. of saline were injected into the cavity. Patient experienced great relief, but profuse sweating occurred. Liver dullness normal in 10 days. Subsequent treatment: seven injections of emetine, 1 gr. and 18 gr. of E.B.I. Patient greatly improved, night sweats ceased, and he gained considerably in weight.

The initial shoulder pain was a dominant feature, also absence of any history of diarrhoea or dysentery, nor any evidence of active infection of the bowel were points worthy of note.

CASE 5.—W., 45, admitted Jan. 8th, 1921, discharged March 7th, 1921. Contracted dysentery in 1917, numerous relapses since. Shoulder and hepatic pain December, 1920. On admission clinical picture suggested acute cardiac distress; liver enlarged downwards below costal margin; dullness and signs of compression at base of right lung, together with intermittent pyrexia. Red cells 4,000,000; moderate leucocytosis 10–12,000 (polymorphs 73 per cent.); no cysts of *E. histolytica* in faeces while in hospital (though previously recorded on numerous occasions). X rays revealed stretching of dome of diaphragm, but little impairment of movement. Aspiration with local anaesthesia; aspirated in ninth interspace in anterior axillary line; 3 oz. thick pus withdrawn and 3 gr. emetine injected. Second aspiration 11 days later yielded 4 oz. similar pus. Owing to persistent pyrexia, in spite of emetine treatment under general anaesthesia, the abdomen was opened and the liver explored (11 punctures) without result. After further emetine injections he rapidly recovered and left weighing 10 st. 2 lb. (an increase of 8 lb.).

In this case the amount of pus was small in relation to the acuteness of the symptoms and the relief obtained after its withdrawal. It is probable that two small abscesses existed.

CASE 6.—C., 23, admitted Feb. 26th, 1921, discharged March 29th, 1921. As seaman had diarrhoea in Calcutta in November, 1920; latterly pain in left side and shoulder, painful swelling, size of large orange, in epigastrium; no pyrexia or diarrhoea or leucocytosis; faeces contained cysts of *E. histolytica*. Aspirated in epigastrium and three pints of pus obtained. After a course of E.B.I. 30 gr., wound healed and patient regained weight and condition.

A remarkable case possibly of a left hepatic abscess, attempting to burst to the exterior through the abdominal wall and at the same time producing

little or no disturbance with only slight pain and no pyrexia.

CASE 7.—Mrs. B., 63, stewardess, admitted April 5th, 1921, discharged June 3rd, 1921. Frequent slight attacks of dysentery during last ten years, three years gradual loss of weight; three months abdominal pain and pyrexia; enlarged painful cervical glands one week. On admission obviously distressed and ill; complexion "muddy," thickly furred tongue, hectic pyrexia, profuse sweats, enlarged cervical and axillary glands. Slight enlargement and tenderness of liver below costal margin; definite abdominal tumour in left hypochondrium, apparently co-extensive with left lobe of liver and in splenic area a tumour, surmised to be the enlarged left lobe of liver. Lungs: Definite signs of compression, dullness at the right base; nocturnal cough. Advanced oedema of both feet; no albuminuria, moderate anaemia, haemoglobin 70 per cent.; red corpuscles 3,000,000; leucocytosis 25,000. Faeces contained no cysts of *E. histolytica*. Heart sounds faint and feeble, pulse rapid (120) and irregular. Aspiration under local anaesthesia in right ninth interspace in axillary line produced 14 oz. of pus; 20 c.cm. eusol solution injected into cavity; immediate great relief. A second aspiration was undertaken after a period of five days, on account of persistence of signs at the right base without result. Pyrexia persisted for over a month. Medicinal treatment, pulv. ipecac. and emetine; of the former she had 155 gr., of the latter 9 gr. by injection.

On admission the physical condition of this patient was critical. The quite evident glandular enlargement, together with multiple tumours, suggested malignant disease. The abscess appeared to be situated in the lower portion of the right and extending into the left lobe of the liver. Improvement subsequent to aspiration was remarkable. A major abdominal operation in this case would undoubtedly have proved fatal.

CASE 8.—A., 27, admitted April 22nd, 1921, discharged July 11th, 1921. Diarrhoea and dysentery in Mesopotamia in 1916, invalidated on this account. In March, 1921, pain in right chest and dull ache in right shoulder, cough, night sweats. On admission anaemic, emaciated, distressing cough, drenching sweats; pyrexia, 99°–101° F. Signs of fluid at right base, superficial oedema in axilla and over hepatic area. Considerable enlargement of liver; fifth rib in anterior axillary line to three inches below the costal margin. Appreciable anaemia; haemoglobin 70 per cent., red cells 3,800,000; leucocytosis 11,000 (polymorphs 59 per cent., lymphocytes 33 per cent.). Faeces normal, no entamoebae or cysts. Aspiration in ninth interspace in anterior axillary line; thick pus obtained, too viscid for aspiration. Resection of ninth rib where pleura was found forced up, pus (6 oz.) successfully evacuated with Cantlie's tube, subsequently exchanged for narrow rubber drainage-tube. Good recovery within a month. After convalescence course of E.B.I. 36 gr., increase of weight 14 lb.

This case illustrates the procedure to be adopted when the pus proves to be too thick for successful aspiration. Resection of the rib was necessary in order to obtain drainage; the wound began to close up three days after operation.

CASE 9.—S., 25, admitted on April 25th, 1921, discharged on May 9th, 1921. Dysentery in Mesopotamia in October, 1918, since when four relapses treated with two full courses of E.B.I. In October, 1921, rheumatic pain in right shoulder, pyrexia and wasting, tongue furred, complexion sallow and muddy—typical appearance. Great enlargement of liver, upwards to the third interspace and downwards into the abdomen; extension laterally into left hypochondrium. Little tenderness on pressure. Haemoglobin 70 per cent.; leucocytes 11,000 (polymorphs 75 per cent.). Faeces: No entamoebae or cysts. Under general anaesthesia liver punctured at point of maximum tenderness at seventh costo-chondral junction; 24 oz. typical pus obtained. Rapid diminution in size of liver. Medicinal treatment consisted of 16 injections of emetine, 1 gr. each. Before leaving hospital he had put on 9 lb. in weight.

A second abscess appeared after a lapse of one year and seven months, for he was readmitted on Jan. 2nd, 1923, with enlarged and tender liver, pyrexia, and a leucocytosis of 15,000. In autumn of 1922 he had complained of intermittent hepatic pain, shoulder pains, nocturnal sweats, and fever. Immediate operation under general anaesthesia and aspiration of 15 oz. of pus in epigastrium. Three weeks' treatment with emetine periodide and discharge on Jan. 30th, 1923.

The only instance in the present series of cases in which another abscess recurred after a prolonged interval. The second aspiration was unattended, as in the first, by any severe constitutional symptoms. The case also demonstrates the possibility of abscess formation after full courses of emetine-bismuth-iodide.

CASE 10.—H., 35, admitted July 14th, 1921, discharged August 15th, 1921. Dysentery in India, April, 1921; relapsed a month later. Soon suffered from hepatic pain, for which he was admitted. Definite enlargement of liver and bulging of chest wall; tenderness on pressure; drenching sweats. Haemoglobin 70 per cent.; leucocytosis 16,000 (polymorphs 85 per cent.); red cells normal. Moderate intermittent pyrexia. Rash on both tibiae resembling squamous syphilide, yielding to potassium iodide. Aspirated in ninth right intercostal space; about 1 oz. pus obtained and 3 gr. emetine were injected into cavity. Medicinal treatment consisted of intramuscular and hypodermic injections of emetine—14 gr. in all. The patient made an uneventful recovery, gaining 5½ lb. in weight.

A straightforward case presenting no unusual features. The good effects of the treatment were obvious.

CASE 11.—V. L., 37, admitted August 10th, 1921, discharged Sept. 27th, 1921. No previous history of dysentery. War service in Mesopotamia. First complained of hepatic pain in May, 1921; pain and swelling in region of gall-bladder, anorexia, and wasting. On admission very emaciated; tongue densely furred; dry lustreless skin. No signs in lungs. No upward enlargement of the liver; fullness in epigastrium, where palpable tumour co-extensive with the liver could be made out, giving the general impression of a malignant growth connected with the gall-bladder or pylorus. Slight pyrexia, no diaphoresis; haemoglobin 70 per cent.; red cells 3,800,000; leucocytosis 12,000 (lymphocytes 36 per cent.). The faeces contained blood and mucus, free forms, and cysts of *E. histolytica*. Aspiration on August 15th, 1921, in epigastrium at the site of maximum tenderness, yielded 8 oz. liver pus. Medical treatment consisted of 10 gr. of emetine followed by a full 12-day course (36 gr.) of E.B.I. Rapid increase of weight and gain of 20 lb.

In this case amoebic dysentery coexisted with hepatic abscess. The situation of the tumour and its apparent connexion with the gall-bladder suggested at first sight malignant disease.

CASE 12.—W., 26, admitted Sept. 3rd, 1921, discharged Oct. 12th, 1921. Dysentery in Palestine in 1920; relapsed several times in 1921. Three weeks before admission was weak and fainted, and in falling hurt his right shoulder; pain persisted, relieved only by supporting elbow. Irregular pyrexia, drenching sweats, dry furred tongue; compression of base of right lung. Leucocytosis of 15,000; haemoglobin 80 per cent. Faeces contained mucus and numerous *E. histolytica* cysts. Wassermann negative. Aspiration through eighth intercostal space in anterior axillary line yielded 2 oz. thick pus free from entamoebae. Treatment, 195 gr. pulv. ipecac. and 7 gr. of emetine followed by a ten-day course of emetine-bismuth-iodide. Patient left hospital having gained 14 lb. in weight.

The shoulder pain was the dominating feature in this case and demonstrates the amount of physical pain and systemic disturbance which may be occasioned by an abscess of such small dimensions.

CASE 13.—U., 44, admitted Dec. 21st, 1921, discharged Feb. 16th, 1922. Dysentery in South Africa in 1918. September, 1921, pain in right side treated with calomel, but became very emaciated and lost altogether 28 lb. in weight; no jaundice, pyrexia, or sweating. Septic ulcer on upper lip; looked extremely ill. Dull, sallow, cachectic; pulse slightly accelerated; no respiratory embarrassment. Dullness at right base from seventh rib downwards; anteriorly from the fourth rib extending into the abdomen; laterally continued to left hypochondrium where the left lobe of the liver was palpable. X ray screening demonstrated immobilisation of the right dome of the diaphragm. No enlargement of lymphatic glands. Definite anaemia; red cells 4,000,000; haemoglobin 70 per cent. Slight leucocytosis, 12,000. *E. histolytica* cysts found in faeces after numerous examinations. On Jan. 11th, 1922, aspirated through eighth intercostal space in mammary line, 64½ oz. reddish-brown liver pus obtained. No entamoebae found. Remarkable improvement followed medication with pulv. ipecac. (gr. x. nocte), and a ten-day course of E.B.I. (30 gr.). End of January, 1922, liver normal size. Weight had increased from 136 to 148 lb., while in March, 1922, he reported weighing 165 lb., heavier than ever in his life. Has remained well ever since.

Here was a liver abscess of very considerable size, producing intense anaemia and cachexia without causing great embarrassment or pyrexia. Had it not been for the moderate leucocytosis and the presence of *E. histolytica* in the stools, the possibility of hepatic abscess could scarcely have been entertained. The recovery was as remarkable as it was rapid.

CASE 14.—K., 56, admitted May 16th, 1922, discharged May 27th, 1922. Diarrhoea in India, July, 1921. February, 1922, influenza with recurrence of dysentery; pyrexia, hepatic pain, and colitis, April, 1922; on emetine treatment intestinal symptoms subsided, but hepatic pain persisted. On admission sallow, nocturnal sweats, tachycardia, extension upwards of hepatic dullness, localised pleural rub in seventh interspace. No marked anaemia; leucocytosis 18,000. Faeces: no cysts of *E. histolytica*. Aspirated May 18th, 1922, under general anaesthesia, through eighth intercostal space; 3 oz. of pus located two inches deep in the liver. Medical treatment consisted of 8 gr. of emetine and he was discharged in order to undergo further anti-amoebic treatment at home.

The advantage of aspiration is brought out by the short duration of the patient's stay in hospital—11 days only!

CASE 15.—B. H., 46, admitted Jan. 8th, 1923, discharged Feb. 20th, 1923. History of amoebic dysentery 1915, with frequent relapses since. Present attack began on Dec. 15th, 1922, with dysentery. On Jan. 4th, 1923, dysentery ceased with the onset of acute epigastric pain, pyrexia, and headache. On admission patient was very toxic, in considerable pain, and the liver, which was very tender, was two inches enlarged downwards. Total W.B.C., 18,000. On Jan. 9th, 1923, under general anaesthetic, liver was explored in epigastrium half an inch to right of midline. Pus located at once close to surface of liver, very viscid, 3 oz. aspirated, no more obtainable, but much necrotic tissue felt. Symptoms partially relieved, but gradually returned, in spite of emetine injections intramuscularly. On Jan. 18th, 1923, with novocaine, re-aspirated 8 oz. of pus. Recovery now rapid. Later E.B.I. course administered. On discharge the hepatic condition was apparently normal, but some muscular paresis still existed, due, apparently, to emetine intoxication.

This case is of interest as showing that emetine alone will not necessarily effect a cure without aspiration.

Note on a Case Treated by Open Operation.

Only one other case of hepatic abscess was admitted to the hospitals under our charge during the latter part of 1919, before the adoption of the aspiration method of evacuating the liver pus. An outline account of the case is given below. Although differing in no essential feature from others of the series (especially Case 13), yet it must be conceded that neither in efficacy nor ultimate result were the results of open operation so satisfactory. The patient was subjected to three operations and remained over six months in hospital. Secondary infection of the abscess cavity with suppurative organisms had obviously taken place. A noteworthy feature of the case was the low degree of leucocytosis in association with an abscess of so large a size.

W., 29, admitted Dec. 30th, 1919, discharged July 2nd, 1920. Dysentery in 1916 in Egypt. Swelling of abdomen September, 1919, with diarrhoea, sense of weight in right side, profuse sweats, slight jaundice. Complexion sallow. Heart's apex, third interspace; half an inch external to nipple line; sounds faint and evenly interspaced. Liver dullness extended from fourth rib to umbilicus. Dullness posteriorly on right side below angle of scapula, measured in mid-sternal line distance from upper to lower limits of dullness, 10 inches. Varicosity of superficial epigastric veins. Slight pyrexia; slight anaemia. Haemoglobin 80 per cent.; leucocytosis slight, 9000, never more. The faeces contained cysts of *E. histolytica*. Abdomen opened under general anaesthesia, and on cutting through the right rectus muscle two quarts of thin liver pus escaped. Drainage-tube inserted which, owing to shrinkage in size of liver, had to be straightened under anaesthetic. Persistent discharging sinus, which became secondarily infected with streptococci through the drainage-tube, and in spite of lavage, scraping and vaccine therapy, refused to granulate up. On May 30th blockage of sinus with re-accumulation of pus occurred, necessitating a further anaesthetic and operative measures. The liver being punctured in other directions failed to yield any more pus; soon after the sinus healed up. Patient received altogether 400 gr. of pulv. ipecac. and 21 gr. of emetine; underwent three operations and was over six months in hospital!

Discussion.

We are firmly convinced, as a result of our experience that aspiration should be regarded as the method of election in liver abscess; not only is the patient not exposed to the same risk and pain as in the open

operation, but also his stay in hospital is considerably shortened. In our series of cases the average stay in hospital was 29.8 days. Not only has the method these advantages, but also aspiration may be safely undertaken under local anaesthesia in cases with respiratory or cardiac embarrassment when operation under general anaesthesia is contra-indicated. We are convinced, too, that the failure of the earlier exponents of this method may be ascribed to the non-recognition of the necessity of anti-amœbic treatment in addition to operative interference. There were no deaths in our series of 15 cases.

Conclusions.

We venture, also, to draw the following conclusions :

(a) *As Regards Diagnosis.*—1. Liver abscess may exist in absence of all suggestive laboratory tests (leucocytosis, pyrexia, ascertainable presence of *E. histolytica*). Therefore in cases of doubt aspiration should be undertaken. 2. A definite leucocytosis may not be present, but even if present, it is not usually a high one. 3. Pain in the right shoulder may be the most prominent and outstanding symptom. 4. Liver abscess may exist in the absence of any pain or tenderness referable to the liver area at all. 5. Entamœbæ may, or may not, be demonstrable in the aspirated pus; their absence, or rather the inability to demonstrate these organisms under the microscope, does not negative the diagnosis of amœbic abscess; neither can these organisms be demonstrated in the faeces in every case. 6. X rays may be of considerable assistance in diagnosis; immobilisation or stretching of the dome of the diaphragm should be regarded as a valuable positive sign.

(b) *As Regards Treatment.*—1. A general anaesthetic is not always required, aspiration can sometimes be successfully performed under local anaesthesia, with little or no immediate risk. 2. All available pus should be aspirated at the one operation. 3. Aspiration is followed by a great sense of relief; there is a complete absence of shock following the operation. 4. Re-accumulation of pus does not usually take place, but if it does aspiration may be repeated and be followed by a permanent cure. 5. The method is applicable to the conditions of general practice. 6. The injection of emetine into the abscess cavity is by no means essential, nor, in our opinion, advisable, but it is most necessary to treat the patient with large doses of emetine bismuth iodide by the mouth in order to clear out, if possible, the source of infection from the bowel, and so to prevent re-invasion of the liver by entamœbæ derived from the bowel wall.

THE TREATMENT OF INTERNAL DERANGEMENTS OF THE KNEE-JOINT.

A NEW METHOD OF OPERATIVE EXPOSURE.

By A. G. TIMBRELL FISHER, M.C.,
F.R.C.S. ENG.,

ASSISTANT TO THE PROFESSORIAL SURGICAL UNIT, UNIVERSITY
COLLEGE HOSPITAL; JOINT LECTURER ON OPERATIVE
SURGERY, LONDON SCHOOL OF CLINICAL MEDICINE.

(With Illustrative Plate.)

THE method of exposure of the knee-joint for anomalous or complicated cases here described is the outcome of a somewhat extensive experience of cases of internal derangements of this joint, for during the last four years alone nearly 400 cases have passed under my observation. Many of these cases had been previously operated upon elsewhere by various surgeons and by various methods, and it has been possible to review the results of the operations without the bias that tends to creep into personal statistics. It is hoped to present a detailed study of the experience gained and of some further researches into the underlying physiological factors and pathological types at some future time. It has, however, been brought home very forcibly to the author that the results of operation for internal derangements fall very far short of the ideal which should be our aim. The percentage of cases with persistence of original symptoms or with troublesome sequelæ is still too high. The factors contributing to an unsatisfactory result are many, but in this paper it is my purpose to deal with one only, which, however, I consider to be one of the most important—viz., inadequate exposure with consequent incomplete operation. One has gradually become convinced that, with certain exceptions, most operations for internal derangement of the knee should be of the nature of an exploratory arthrotomy. This particularly applies to cases of long standing or with anomalous symptoms.

We are presented with an analogy in abdominal surgery. A comparatively short time ago it was considered a somewhat brilliant procedure to remove the chronically inflamed (*sic*) appendix through a button-hole incision. With a fuller knowledge of the multitudinous conditions which may simulate the chronically-inflamed appendix, and with the knowledge that the peritoneum, if treated kindly, is a good friend to the surgeon, abdominal operations partake more and more of an exploratory nature. Similarly, the synovial membranes of joints, if treated with respect, are good friends to the surgeon, and with careful technique aseptic results should be automatic, and there would appear to be no justification from this point of view for the small openings in the joint capsule so often employed.

Arguments in Favour of Exploratory Arthrotomy.

(a) *The Difficulty of Arriving at a Definite Diagnosis.*—It is notoriously difficult to arrive at an exact diagnosis in cases of internal derangement of the knee. I have come across several cases where symptoms have pointed to a lesion of the internal semilunar cartilage, whereas the external cartilage was at fault, and vice versa. I have known typical locking and limitation of full extension of the knee, which could not be reduced by manipulation, to be produced by a loose body. Furthermore, symptoms exactly simulating a lesion of a semilunar cartilage may be produced by hypertrophy of (Fig. 1), or hæmorrhage into, a synovial fringe (Fig. 2) or alar pad (Fig. 3). Loose bodies may be present and may be single or multiple, pedunculated or free. Again, sudden giving way of the knee is an exceedingly common symptom in osteo-arthritis with or without the presence of a definite mechanical cause. Rarer causes of anomalous symptoms are foreign bodies in the joint, isolated lipomata (Fig. 4), diffuse osteo-chondro-

matosis of the synovial membrane, and sarcoma (Fig. 5). Extra-articular causes, such as exostoses, interfering with tendon action, which may give rise to somewhat similar symptoms, must be excluded before arthrotomy.

(b) *Coexistent Pathological Factors.*—A fact of fundamental importance, which is not yet sufficiently understood, is that many cases of internal derangement of the knee, particularly those that have persisted over long periods, are associated with other intra-articular pathological conditions. Some of these have already been mentioned. The loose bodies deserve a little further mention. The presence of synovial chondromata or osteo-chondromata is, in my experience, not infrequent in association with a damaged semilunar cartilage, or with a detached portion of the articular surface forming a loose body. They are usually associated with chronic synovitis and with the increased vascularity of the synovial membrane which accompanies this, or, on the other hand, they may be associated with the increased vascularity of the membrane that I have shown to occur in the earlier stages of osteo-arthritis. Occasionally one sees in the same joint, associated with some mechanical derangement, loose bodies that have arisen in this manner, and also those which have their origin in detached periarticular chondro-osteophytes, occurring in osteo-arthritis. I have encountered hypertrophy of the infra-patellar pad of fat, which may become densely fibrous—so that it cuts like an unripe pear—or cartilaginous, or even bony. It is impossible in a short paper to do more than briefly touch upon some of the commoner coexistent pathological conditions. It is desired to emphasise that in the absence of an adequate exposure coexistent conditions are particularly liable to be overlooked.

It is often asked, "Is it justifiable or desirable to operate upon cases of internal derangement in which osteo-arthritic changes have supervened?" The answer is that no hard-and-fast rule can be formulated, and that each case must be treated on its merits. In every case the age and general condition of the patient, the stage of the disease, whether progressive or quiescent, and the proportion between the symptoms due to the osteo-arthritic condition, and those due to mechanical derangement, have to be carefully considered. If the changes are localised, and evidently due to mechanical irritation, they will obviously progress while the cause persists, and there is reason to believe that such an operation may prevent generalised changes. It is surprising to find in many cases quite a marked degree of osteo-arthritis which is giving rise to remarkably few symptoms per se, and yet locking or sudden giving way of the joint is due to some definite mechanical cause. In these cases, the removal of the latter, where possible, may prove to be a very satisfactory procedure.

Criticism of Some Common Operative Exposures of the Knee-Joint for Internal Derangement.

(a) *Transfixion and Local Removal of a Loose Body.*—Although this method is still recommended by many modern text-books, it is an unscientific relic of pre-antiseptic days, when the opening of a joint was a formidable procedure. A full exposure of the joint is imperative, and failing this other conditions or coexistent loose bodies not always evident in the skiagram will almost certainly be overlooked. There is, however, no objection to transfixion provided that a complete exposure follows.

(b) *Curved or Straight Lateral Incisions over the Joint Interval.*—These incisions, save in very exceptional circumstances, do not yield such satisfactory results as the more complete exposure to be described later; and through them it is impossible to explore fully the anterior compartment of the joint save by digital examination. The latter procedure is to be thoroughly deprecated. The finger under no circumstances should be introduced into the joint. Although surgeons still exist who advocate this procedure, it is extraordinarily significant that these are the same

surgeons who advocate post-operative drainage of the joint. By the exposure to be shortly described, the whole of the anterior compartment of the joint, including the supra-patellar pouch, is exposed to sight by suitable retraction. Through the semicircular incision it is, moreover, easy to remove a structure which may resemble the semilunar cartilage very closely, but which, in reality, has originated in an extension of the infra-patellar pad of fat upwards near the patellar margin. I have before me as I write such a specimen; it is composed of dense fibrous tissue of almost cartilaginous consistency, and closely resembles a semilunar cartilage. The operator was on the point of closing the joint under the impression that he had removed the cartilage, when further retraction revealed the latter still present.

(c) *Transpatellar Route.*—This undoubtedly gives a good exposure of practically the whole of the anterior compartment, and, doubtless, in the hands of the master who originated the method, it is an excellent procedure and attended with good after-results. I believe, however, that the method to be described later is simpler in performance, gives a better exposure, is a less severe operation, since it involves no division of bone or articular cartilage, is less likely to be followed by osteo-arthritic changes, and is attended with a shorter convalescence. It appears to have been hitherto overlooked that there are objections on physiological grounds to the transpatellar route, particularly if the most accurate apposition of bone and cartilage be not obtained. It has been shown that no true cartilaginous repair takes place in incisions in the centre of articular cartilage, but that incisions, if they heal at all, do so by an imperfect fibrous tissue. Moreover, I found experimentally that in certain cases not only did failure of union occur, but the cartilage on either side of the incision underwent necrosis. If, moreover, we examine the specimens of fractured patella in pathological museums we shall see in many cases degenerative changes in the articular cartilage surrounding the site of cleavage. It appears that in these cases, particularly when apposition is not perfect, the irregularity and imperfect union of articular cartilage actually act as a source of irritation and may, particularly in individuals past the meridian of life, set up a form of traumatic osteo-arthritis. The latter may not necessarily be sufficiently marked to be apparent on X ray examination, but is clinically recognisable by a harsh "nutmeg grating" on moving the patella from side to side upon the trochlear surface of the femur with the knee extended, and also by aching and pain after exercise.

The Operation.

The stages described are particularly applicable to cases where symptoms point to the inner side of the joint. If symptoms point to the outer side of the joint, the positions of the incision in the skin and capsule are reversed. The skin is prepared by the iodine method and a tourniquet used. Aseptic results are in my clinic automatically obtained.

Stage 1.—Make a slightly curved incision through skin and subcutaneous tissues (Fig. 6). This incision commences above in the mid-line an inch above the uppermost limits of the supra-patellar pouch, skirts the inner border of the patella and the inner border of the ligamentum patellæ, and ends below slightly to the inner side of the tubercle of the tibia. The flap of skin and subcutaneous tissues is reflected outwards to slightly beyond the outer border of the patella. The skin flaps are protected by gauze, or the incision may be made through a covering of sterile gauze or stockinette which is afterward clipped to the skin edges.

Stage 2.—Make a mid-line incision through the well-defined layer of fascia covering the quadriceps tendon (Fig. 7). Prolong this downwards and slightly inwards to the middle of the upper border of the patella. Thence continue in the mid-line of the patella through the same layer of fascia and through the somewhat thinner fascia covering the centre of the ligamentum patellæ as far as the tubercle of the

tibia. This incision should avoid the subjacent quadriceps tendon, the periosteum on the front of the patella, and the ligamentum patellæ.

Stage 3.—The above-mentioned fascia is raised and reflected inwards by a few light touches of the scalpel (Fig. 8). Above, a few fibres of the vastus internus may with advantage be included in the base of the flap. Below, the base of the flap should be half an inch from the inner border of the patella and from the inner border of the ligamentum patellæ.

Stage 4.—The above-mentioned fascial flap is to be well retracted inwards by the assistant. Next the capsule is divided a quarter of an inch from and parallel with the inner border of the patella (Fig. 8). The incision is carried upwards somewhat obliquely through the inner fibres of the quadriceps tendon, carefully avoiding any muscular fibres of the vastus internus; and below, the incision is carried through the capsule at the inner border of the ligamentum patellæ (see dotted line Fig. 8). The synovial membrane is next divided along the line of division of the capsule save in the extreme lower part of the incision.

Stage 5.—The patella is dislocated to the outer side of the joint, and on further flexion of the joint an excellent exposure is obtained of the whole of the anterior compartment (Fig. 9). The introduction of the finger into the joint, as already mentioned, is

It is my practice to suture the synovial membrane with a continuous suture of fine catgut. The incision in the alar pad should be carefully sutured, but if the latter is pathologically enlarged, it should be removed. The capsule is next sutured with a continuous suture of stout chromicised catgut. Next the flap of fascia is replaced and sutured in the mid-line with a continuous suture of medium-sized catgut. Thus the opening into the joint is closed after the fashion of a double-breasted coat. The skin is sutured with interrupted silk-worm gut sutures. The tourniquet is not removed until dressings and bandages are firmly in position.

After-treatment.

No splint is used. The limb is supported in a position of slight flexion with pillows. The silk-worm stitches are removed on the seventh day, and massage and movements, both active and passive, instituted, the patient being allowed to sit in a chair daily. At the end of two weeks the patient is allowed to commence to walk about. Massage and movements are continued. At the end of three weeks patients are usually able to walk fairly well, and at the end of the fourth week almost normally. Post-operative swelling is rare in my experience, and I believe it to be usually due either to the trauma inflicted on the synovial membrane by inadequate

FIG. 6.

FIG. 7.

FIGS. 6, 7, 8, 9.—Stages of the operation of exploratory arthrotomy of the knee-joint, described in the text.

quite unnecessary, since with suitable retraction every part is brought into sight.

It will have been noted that the lower portion of the incision in the capsule opens up the region of the infra-patellar pad of fat and alar pad (so-called "alar ligament") which here project into the joint. This is next divided if necessary, one or two ligatures being often desirable at this spot even if a tourniquet be used. If the operation be performed for loose bodies, this stage is not always necessary. This step, however, undoubtedly facilitates the dislocation of the patella and gives an even better exposure. In Fig. 9 a "bucket-handle" type of lesion of the internal semilunar is represented, and was drawn from an actual case. The ligamentum mucosum is not represented, as it was absent in this case. I have not found that normally it obstructs the view of the opposite side of the joint. If, however, it is unusually well developed, it may be divided and subsequently sutured.

Personally, I cannot see any objection to moving the joint during the operation, and have more than once been upon the point of closing a joint after a careful search has revealed nothing abnormal, when, on flexing or rotating the knee, a loose body has shot out from the back part of the joint, or the detached posterior end of, or a tag of, cartilage split from the circumference of the semilunar cartilage has come into view.

On completion of the intra-articular stage, the knee is extended and the patella is easily replaced.

exposure, or to a mild degree of sepsis due to the introduction of the finger into the joint. Both factors are necessary concomitants of inadequate exposure.

Illustrative Cases.

The following are illustrative cases, selected from a large series.

CASE 1.—A man wounded in the right knee in August, 1915, at the Dardanelles by a shrapnel bullet. A short note made in August, 1917, states: "Knee creaks on movement, no fluid present. Flexion to 90°. Extension full." October, 1920: "Loose body can be felt. Knee swells after walking three or four miles. Movements as before." December, 1921: "A loose body was removed from the joint through a small incision on the outer side."

Condition on Admission.—Right knee: Two small healed scars present, one at the outer side of the patella, the other in the popliteal space. Small operation scar on outer side over joint interval. Well-marked thickening of synovial membrane on either side of patellar ligament. No obvious lifting of articular margins present.

Movements.—These, accompanied by harsh crepitus, were as follows: Flexion slightly restricted; extension full, but in passing from angle of 135° to full extension there is a very obvious sudden slipping forward of the tibia over some obstruction in the outer part of the joint with an audible "click." Some wasting of the thigh. X ray examination, in addition to showing a mass of new bone projecting into popliteal space, reveals the presence of many loose bodies in the anterior compartment of the joint, one of which lies in the supra-patellar pouch (Fig. 10).

Operation.—This was performed by the method detailed above. The external alar ligament or pad, with the corresponding part of the infra-patellar pad of fat, was found

studded with osteo-chondromatous nodules (Fig. 11), which, although projecting slightly into the joint cavity, were for the most part deeply embedded. The affected area was removed entire. A similar body, with a very long twisted pedicle, was removed from the supra-patellar pouch, and several enlarged synovial villi, apparently not as yet chondrified, were removed. The posterior end of the external semilunar cartilage was found completely separated from its attachments and displaced forwards so that it was in contact with the anterior half (Fig. 12). The whole cartilage was removed with the greatest ease. There were no obvious signs of osteo-arthritis present. The wound was sutured in the usual fashion.

This case is of interest in demonstrating the advantage of a complete exposure and the futility of limited incisions in such cases. It is possible also that the passage of the shrapnel bullet through the joint caused the displacement of the posterior horn of the semilunar cartilage. The patient has made an excellent recovery, has full movement in the joint, and is free from symptoms. The cause of the persistent synovitis having been removed, as also all enlarged villi, the prognosis is good, particularly as osteo-arthritic changes are absent.

CASE 2.—This is an example of the advantage of the exposure in a case of osteo-arthritis with loose bodies. The patient stated that he first noticed loose bodies in his right knee-joint in 1916. The knee is weak, but the principal trouble consists in frequent giving way of the joint with temporary locking. There is one inch wasting of the right thigh. X ray shows well-marked osteo-arthritic changes with general lipping of the articular margins, and two large loose bodies in the supra-patellar pouch.

Operation.—Exposure as above. Partial erosion of central parts of articular cartilage noted with well-marked lipping. Two disc-shaped cartilage-covered loose bodies were removed from the supra-patellar pouch. These were obviously detached chondro-osteophytes. A small pedunculated cartilaginous growth was removed from the lower end of the anterior crucial ligament, and two other portions of synovial membrane loaded with hypertrophied villi were removed.

Result.—Patient markedly improved. No longer complains of giving way of the knee. Movements are full.

In many cases of osteo-arthritis the principal symptom consists in painful locking or giving way of the knee. These are particularly suitable cases for operation, other things being equal. With early movements and careful after-treatment no limitation of movement need be expected. In cases with effusion it has the additional advantage that the thick, often jelly-like, synovial fluid can be evacuated and the joint thoroughly flushed out with an antiseptic. In many cases this procedure has in my hands apparently cut short the disease.

CASE 3.—The patient fell and twisted his knee on Jan. 5th, 1921. Was in hospital for several weeks and treated for "synovitis of knee." On May 30th the knee gave way suddenly and he fell, fracturing his right humerus. On August 8th the internal semilunar cartilage was removed elsewhere. On Nov. 21st he complained of pain on full flexion and extension. Small amount of fluid present. Walked with a limp and stated knee was weak. There was pain on outer side of patella. On April 5th, 1922, external semilunar cartilage removed elsewhere. On June 8th he stated knee was worse. Considerable amount of fluid present. The joint still "let him down."

Condition on Admission.—Two curved incisions were present, on inner and outer aspects of joint respectively. There was some thickening of the synovial membrane but no free fluid. Full flexion of the knee was restricted and painful. No evidence of osteo-arthritis, but X ray showed unnatural opacity of the infra-patellar pad of fat.

Operation.—On full exposure by above-mentioned incision it was seen that both semilunar cartilages were present. The internal was normal, but the external, although not fractured or completely detached from its periphery, was abnormally loose, with a fibrous and attenuated inner border, and was accordingly removed. The infra-patellar pad of fat was markedly thickened, and, after removal, cut like an unripe pear, owing to the dense fibrous tissue it contained. The joint was closed in the usual manner and the patient is making an uneventful recovery.

The fact that this patient had undergone operations by the "classical" routes upon both cartilages, and a more complete exposure showed them to be both present is particularly instructive. The finding of a cartilage alleged to have been removed has

befallen me several times, and it is a strong argument in favour of complete exposure.

CASE 4.—A seaman aged 35. Eight weeks before admission the ship pitched and he fell with his weight upon his right knee upon the deck. The knee was locked for a short while and became swollen. He lay up for five days, but afterwards carried on his duties.

Condition on Admission.—He complained of swelling of the joint, pain on walking, and frequent "giving way" of the knee. X ray showed some diminution of the joint interval on the inner side, but joint surfaces were quite clear. This fact was of interest in view of the operation findings. There was some thickening of synovial membrane, particularly on inner side of joint. No fluid at time of examination; movements full; no lateral mobility. There was well-marked tenderness over anterior end of internal semilunar cartilage which became accentuated when, on fully extending the leg, the anterior end came in contact with the finger. Owing to this fact it was considered unlikely that the condition was one of simple displacement of the anterior end of the cartilage. The diminution of the joint interval on the inner side, with also the presence of full extension, appeared to point to a "bucket-handle" type of lesion, and this was subsequently confirmed.

Operation.—This was performed by the above-mentioned route. A splendid view of whole of anterior compartment of joint was obtained. A "bucket-handle" type of lesion of the internal semilunar cartilage was seen to be present (Fig. 9). A longitudinal split had occurred; one portion had been displaced into the intercondylar notch, whereas a narrow portion of the cartilage still remained attached to the capsule. No osteo-arthritic changes were present.

In lesions of the semilunar cartilage of this type a complete exposure of the anterior compartment of the joint is particularly to be desired, as otherwise the portion of the cartilage lying in the intercondylar notch may easily be overlooked.

CASE 5.—Male, aged 47, twisted the right knee at football 19 years ago, after which the knee occasionally gave rise to trouble which, however, was not a serious source of inconvenience, until he received a kick from a horse in 1916. After this second accident the knee frequently gave way, locking being followed by synovitis and joint effusion. In 1918 arthrotomy was performed, exposure being obtained through a curved incision on the inner aspect over the joint interval. Unfortunately, no report of this operation could be obtained, but his symptoms persisted as before and were in no way improved.

In 1921 the attacks of locking were marked, and, in addition, the pain and swelling were so far increased that an eminent surgeon recommended immobility and extension by means of a Thomas ambulatory calliper splint. In 1922 he was operated upon by a London orthopaedic surgeon, exposure being obtained through a curved incision on the inner aspect of the articulation, "a considerable portion of the internal semilunar cartilage being removed." But there was no improvement in his condition.

Condition on Examination.—I examined him three months later, and found a condition of chronic synovitis with effusion. Flexion was not possible beyond an angle of 90°. Clinical and X ray examination both negatived osteo-arthritic changes. Two small superimposed healed incisions were present on the inner side of the joint. As was not surprising, the patient's attitude was one of scarcely veiled opposition towards the medical profession; he had suffered much of many surgeons during the past seven years, at least two of whom were of European repute. He was, however, anxious for something further to be done.

Operation.—An excellent exposure of the whole of the anterior compartment of the joint was obtained by the method under discussion. The synovial membrane was obviously in a state of chronic inflammation, and certain necrotic fringes on the point of detachment were removed, as were also a few loose "melon-seeds." At first no mechanical cause of derangement could be seen, but on more careful examination it was found that the posterior end of the internal semilunar cartilage was still present, was loose, and was evidently the cause of the persistence of the locking and synovitis. There was a complete absence of true osteo-arthritis. By exercising a little patience the offending fragment was completely removed. On account of the condition of the synovial membrane it was considered advisable to wash out the joint cavity with sterile normal saline solution.

After-history.—This patient made an uneventful recovery and one of the most rapid in my series of cases; four weeks and one day after the operation he left my care, walking almost normally, with a full range of joint movement and complete absence of effusion. There has been no recurrence of his previous symptoms.

pectoris, due to an aortic or coronary lesion, and, lastly, he died from intestinal infarction, terminal syndrome of arteritis of the mesenteric artery.⁷ It should also be noted that symptoms of intestinal arterio-sclerosis (paroxysmal abdominal pain, colic stasis) were absent, and that this lesion manifested itself only in its terminal syndrome, the intestinal infarction.

The second interesting clinical point was that diagnosis was made during life. In our case there was absence of hæmatemesis and sanguinolent diarrhoea—symptoms considered as characteristic of this affection. We founded our diagnosis on the fact that the patient showed an acute peritoneal syndrome, and had a long history of athero-sclerosis with arterial clinical manifestations. Our attention was directed towards the mesenterio-vascular thrombosis on account of a case published by one of us in collaboration with Dr. Laignel Lavastine,⁸ showing that the diagnosis of intestinal infarction can be often made if this possibility is borne in mind, as should always be done, for, as recently proved by Fernandez Martinez of Grenada, it is frequent enough.

Integrity of the Small Intestinal Vessels.—Lagane¹ in a very important work on intestinal arteritis affirms that the obliteration of an important artery is not in itself sufficient to produce complete and extensive intestinal infarction, and that the additional factor necessary is obliteration of the small vessels in the intestinal wall—arterioles, venules, capillaries—otherwise a compensatory collateral circulation would be established. Lagane's view is not proved by any anatomo-clinical observation. On the contrary, in our case the little vessels of the intestinal wall are intact (Fig. 2), some of them even showing dilatation of their lumen. Our view, founded on the present case, is that the lesion of these little vessels is not necessary, and that, even when healthy, these vessels cannot establish a sufficient collateral circulation. It is not the first case met with in pathology of an anatomically non-terminal artery which comports itself physio-pathologically as a terminal one. The entire vascular territory of the superior mesenteric artery can be injected by anastomatic channels from the aorta, but in the living being different conditions control the distribution of the circulating blood. And in the case of a rapidly developing obliteration of the main stem, or of an important branch, these anastomoses are not sufficient.

Intestinal Emphysema.—Our case presented a morbid change which is not described as a sequel of mesenteric obliteration—namely, "intestinal emphysema." The intestinal coils were distended in great part with gas, bubbles small and big being found in the submucosa. (In this connexion it should be remembered that the necropsy was made eight hours after death.)

Pathological Physiology of the Infarction.—From this observation the mechanism of the production of the infarction may be regarded as follows: The circulation of the blood through the arteries of our patient was much interfered with, and with the onset of heart failure became worse. Slowing of the blood flow in the vessel and disease of its walls were the two conditions favouring the production of thrombosis. On the other hand, heart failure which diminishes the blood pressure in the arteries raises it in the veins, and consequently in the territory of the portal vein. When the mesenteric artery is obliterated and one of the most important factors in venous circulation disappears, this pressure becomes much greater, and retrograde inflow of blood from the portal vein territory is provoked. The conditions found at the necropsy of our patient provide proof of this retrograde circulation; the liver was paler than usual and a little anæmic, the reverse of what is found in heart failure. The mesenteric veins, even the finest venous twigs, are crammed with blood. But arterial ischæmia and venous hyperæmia are not sufficient to provide the physio-pathological key to the condition under discussion, and for the production of the necrosis of the tissues microbial intervention must be postulated.

Our preparations show abundant bacterial infiltration, with a bacillus morphologically resembling *Bacillus perfringens* or *Bacillus phlegmonis emphysematosæ* of Welch, which are anaerobic gas producers and belong to the normal intestinal flora. Diminished resistance of the intestinal mucosa no doubt favoured the multiplication of these bacilli and probably the increase of their virulence.

Conclusions.

In this case hæmorrhagic infarction of the intestine appeared as a terminal syndrome of intestinal athero-sclerosis, of which it may be the only clinical manifestation. It can be diagnosed, if the thoughts of the clinician are directed towards this syndrome, even in the absence of the pathognomonic sanguinolent diarrhoea. It is produced even in the absence of alterations of the small blood-vessels, by obstruction of a sufficiently large artery. The arterial ischæmia and the venous stasis resulting from this obstruction impair the defensive mechanism of the intestinal mucosa and promote multiplication and augmentation of the virulence of the anaerobic bacilli which determine necrosis. The gangrenous necrosis in this case was a real gas gangrene.

AN EPIDEMIC OF "FOURTH DISEASE."

By HUGH M. RAVEN, M.R.C.S. ENG.

THE diagnosis between scarlet fever, German measles (epidemic roseola), and "fourth disease" is proverbially so difficult that I think the following account of an epidemic, of which no diagnosis could be made at the time, is of interest, and should elicit valuable experiences and views from others.

In June and July, 1922, in a school of 80 girls and staff, there was an epidemic of 12 cases with the following symptoms and course. The onset was acute with temperatures varying from 102° to 104° F.; slight vomiting in two cases, otherwise none; and on the first day a scarlatiniform rash, scarcely affecting the face, but coming out at once all over the body and legs where it was somewhat raised and very irritable. This latter symptom was marked in nearly all the cases. The cases with the highest temperatures did not necessarily have the most copious rashes; only where the temperatures were high was there any rise of pulse-rate, and then only in proportion to the temperature. The throats showed a scarlet injection of the palate and fauces. The pyrexia lasted from seven to ten days. The tongues, though not covered with a thick white fur, peeled typically about the fourth day. The glands were not much enlarged in the early stage except in one case, where the posterior cervical group were involved; but in this case, and in three others there was secondary enlargement with pain and a little fever. Peeling began on the fifth to seventh day on ears, neck, and body, some powdering of the face, and was quite definite and complete, including the hands and feet, in all but two cases. One case, however, never peeled at all. But it is interesting to note that the desquamation had no relation to the intensity of the eruption. There was slight albuminuria in one case only, and no rheumatism or other complication in any. None of the patients could be called ill or toxic, although one patient became somewhat

exhausted with attacks of recurring enlarged glands, and left-sided peritonitis in the third and fourth weeks.

Cause of Infection.

The cause of the infection was reduced to one of two sources: (1) A concert attended by the whole school in a neighbouring town, where, I heard, there had been some cases of scarlet fever and German measles; the concert was 18 days before the first three, and 21 days before the fourth case (a mistress). (2) A maid developed a fibrinous tonsillitis (which proved not to be diphtheritic) seven days before the first three cases. She came from another neighbouring town where scarlet fever had been prevalent. After a few days she developed a quinsy, not the first in her life, and went home to convalesce, returning to her duties at the school on July 1st.

The parents of the children had been notified when the first four cases occurred, and a good many pupils had returned home. About 20 days after the first four cases, one child was taken ill at home, and her medical attendant diagnosed mild German measles, slight rash, slight faucial redness, a cold, and no peeling. (Only one other child was reported ill after returning home, developing measles on August 12th, and I cannot think that this has anything to do with our cases.) On July 6th four more cases occurred, on the eighteenth day after the removal of the first four to the sanatorium, and five days after the maid returned to the school; and this time the latter was sent home for good. The second four cases conformed to type, perhaps a little less severe; marked scarlatinal rashes, very irritable on the legs, red throats (two with some follicular tonsillitis, and these two children had later glandular complications). I may note here that one of the first four cases was a child who had had chorea; though her pyrexia was somewhat persistent, and her usual movements rather more marked, she did not develop endocarditis, or recur as an acute chorea.

Diagnosis of Scarlet Fever.

At this stage, all the cases were seen by an experienced colleague, who diagnosed them as scarlet fever. Three other patients developed the disease 18, 19, and 20 days from the second batch of children. Two conformed to type and peeled markedly; one of these had secondary enlarged glands and slight albuminuria. This was the school matron, who was said to have had German measles twice; she had the rash on her face, and also some conjunctivitis. The second case was the sanatorium maid; the third was a maid in the school whose rash was somewhat morbilliform and did not peel, but without catarrh and with the red throat. It should be mentioned that one of the children is said to have had scarlet fever, and one to have had German measles.

Here we have an epidemic with an incubation period of 18-21 days with all the signs and symptoms of scarlet fever, and without widespread infection to others. The occurrence of the case of tonsillitis just before the epidemic, and her return six days before the second four cases may have been misleading; yet had she been allowed to remain who can tell what further cases might have arisen? Apparently she infected no one at home.

The Case Against Scarlet Fever and Roseola.

On reflection one feels that the cases conform most closely to the description of "fourth disease," but I think it would be a brave medical officer who would risk not treating them as scarlet fever, while my experience of roseola has never brought me in contact with cases of such rashes and throats without catarrh, enlarged posterior cervical glands, and a wide epidemic.

For simplicity I tabulate as follows the important points against scarlet fever: (1) Incubation (assuming the maid did not start the epidemic); (2) no sequelae or complications, except secondary enlarged glands; (3) no early vomiting, except in two cases slightly; (4) the case of German measles developed at home and possibly the last case described. Against roseola was the following evidence: (1) Acute onset with high

fever; (2) almost universal absence of rash from the face; (3) peeling tongue; (4) absence of catarrh, especially in the eyes (except one case).

I am disposed to agree with Dr. C. Dukes,¹ of Rugby, that German measles is a diagnosis loosely applied to two diseases—epidemic roseola and "fourth disease," which should not be confused. The danger of confusion is much greater between "fourth disease" and scarlet fever. But, after all, what is the value of a diagnosis when one is not able to isolate an organism? I am led to think that the streptococcus and its numerous relatives are at the bottom of most of these cases, and that the toxin of the various members of the family, virile or less active, of the first or third or fourth generation, may produce an irregular, though similar, series of manifestations. I should be very glad to be told of references to bacteriological work on this subject, which might be helpful when faced with such an epidemic.

Broadstairs.

NOTE ON THE OPERATIVE TREATMENT OF MALIGNANT DISEASE,

WITH SPECIAL REFERENCE TO THE TONGUE.

By HERBERT J. PATERSON, C.B.E., M.C. CAMB.,
F.R.C.S. ENG.,

SENIOR SURGEON, LONDON TEMPERANCE HOSPITAL.

It will hardly be disputed that within the last decade the operative treatment of carcinoma has not made such strides as might have been anticipated. It behoves us from time to time to search out the reason for lack of progress, and to consider our technique, to see if in any way this is at fault, or in what way it can be bettered. I sometimes wonder whether we appreciate fully the part played by the lymphatic glands in Nature's defence against the spread of carcinoma. May it not be possible that in modern surgery the glands are attacked too ruthlessly?

Two truths are established. A malignant growth spreads peripherally by invasion of the surrounding tissues, and distally by permeation of the growth through the lymphatics to the lymphatic glands into which they drain, which thus become infiltrated with growth. Most surgeons have met with cases where operation for a malignant growth has been necessarily incomplete, in that glands obviously infiltrated have been left behind, in spite of which fact the patient has lived 10, 12, or even more years, and in some instances has apparently been cured. Is it not a fair inference from this that the lymphatic glands are Nature's defence against distal spread of the disease—in other words, that such patients have lived, not in spite of, but because of the incomplete removal of glands? It seems clear that the lymphatic glands arrest, for a time at any rate, the progress of cancer cells; it is even possible that they may be able to a limited extent to deal effectively with such cells. Does this suggest a modification of our technique?

Possible Advantage of Glands as Wound "Scavengers."

The modern practice aims at the removal of the whole of the growth, together with all contiguous glands, in one piece. If we could be certain of removing the whole of the growth and leaving no isolated cancer cells behind, this procedure would undoubtedly be correct. In practice, however, it must be rarely possible to remove a malignant growth without leaving a few cells, either in the surrounding tissues or in the wound, as a result of the necessary manipulation of the growth. When cancer cells are left in a wound some or all of them probably permeate along the lymphatics to the nearest lymphatic glands, where, temporarily at any rate, their progress is arrested. If, then, all removable glands have already been removed, the

¹ THE LANCET, 1900, II., 89, 1384.

cancer cells may find their way to more distant groups of glands which are beyond the reach of surgical intervention. It is possible, therefore, that if the glands draining the region occupied by the growth are left, they may arrest the cancer cells which have remained behind, and prevent their spreading to more distant parts. After these glands have thus "scavenged" the operation area they can be removed before the cancer cells arrested in them have time to spread to more remote regions. These considerations are especially applicable to cancer of the tongue. In operation for lingual carcinoma it is obviously impossible to remove the growth and glands in the neck in one piece. A track of lymphatics is left between the site of the growth and the glands in the neck. This is one reason why operation for cancer of the tongue is followed so frequently by rapid recurrence. The lymphatics in this irremovable area are permeated with cancer cells. These cells may multiply in situ or migrate to distant glands leading to metastases. This suggests the speculation, what would happen if, when the growth is removed, the glands in the neck were left for the time being. Might not the cancer cells left behind be temporarily arrested in the glands of the neck?

Operation in Two Stages.

These hypotheses suggested a trial of the results of operation in two stages—i.e., removing the growth at the first operation, using cautery rather than knife,

and then three or four weeks later removing the glands. It seems to me that in this way any cancer cells left behind in the lymphatics would find their way to the nearest glands and be removed with the glands at the second operation. I operated for cancer of the tongue by this method five times previous to the war. During the war I had no further opportunity of trying this method. The results in these few cases are so encouraging as to suggest further trial of this plan of campaign. The first operation was performed in January, 1914, and the growth was reported by Dr. E. F. Bashford to be of a very malignant type. In 1921, seven years later, this patient came to see me, and to my surprise I could find no trace of recurrence either in the mouth or neck. This prompted me to inquire as to the results in the other four patients. I traced three of them and found that they were all well, nearly seven years after operation. Presumably the remaining patient had died.

I would suggest, therefore, that in cases of carcinoma of the tongue (1) the growth be removed by the actual cautery; (2) three weeks later the glands in the neck be removed in the usual way.

I have latterly been trying the same plan in operation for breast carcinoma, but whether it is advantageous or not it is too early to say, but as far as cancer of the mouth is concerned it seems to be a rational procedure worthy of further trial.

Clinical and Laboratory Notes.

A CASE OF STREPTOCOCCAL MENINGITIS.

BY STEPHEN G. ASKEY, M.D. CAMB.

THE following case of streptococcal meningitis with operation and recovery is of interest.

History.—The patient was a boy, aged 12, whose family history was good. For two and a half years he had had slight cervical lymphadenitis; in the abdomen he had a few palpable glands and occasional attacks of pain. He was subject to naso-pharyngeal catarrh with temporary deafness, and was often unwell and away from school for a few days at a time. In 1919 Mr. A. C. Gavin removed his tonsils and adenoids.

Condition on Examination.—On Jan. 22nd, 1923, I saw the boy on account of earache. He had considerable deafness, especially on the right side; right tympanic membrane slightly thickened; no mastoid tenderness, but a small gland below the right pinna was very tender. Several slightly tender glands along anterior aspect of upper third of right sterno-mastoid, and some enlarged glands on left side of neck also. These glands were larger a year ago.

Further Examination.—On Jan. 26th Mr. Gavin saw him and reported deafness in both ears with the right tympanic membrane indrawn and thickened. Rinne tuning-fork test negative in both ears. A soft whisper heard at 12 ft. from either ear. Right tympanum ventilated inadequately owing to a nasal spur meeting right inferior turbinal and blocking this side of nose.

Course of Case.—On Jan. 29th he began to have great occipital neuralgia on the right side, with normal pulse and temperature and no mastoid tenderness. On Feb. 3rd I saw him at 11 A.M., when he still had neuralgia; pulse and temperature normal, no visible change in ear, no vomiting, fundi normal, knee-jerks normal. Owing to persistent neuralgia I warned the parents of the possibility of meningitis. Half an hour after I left the house the boy vomited violently without warning. I saw him again about 2 P.M., when he was vomiting. The occipital neuralgia had ceased and he complained of left frontal headache. The temperature was 103.5° F., and the pulse-rate 108. There was no mastoid tenderness; Kernig's sign absent, neck muscles normal. Left knee-jerk present, but right knee-jerk only just obtained on reinforcement. Plantar reflexes indefinite; no nystagmus.

At 9 P.M. Dr. A. E. Russell saw him. Kernig's sign then present, neck muscles definitely rigid, knee-jerks absent except for a flicker on the right on reinforcement. No paralysis of eye muscles, no mastoid symptom. Lumbar puncture under light anæsthesia revealed a turbid cerebro-

spinal fluid under reduced pressure. Prof. L. S. Dudgeon examined the fluid that night and reported a pure culture of streptococcus the next morning.

Operation.—On the 4th Mr. W. H. C. Romanis saw the boy, who was vomiting frequently. Although there were no signs whatever of mastoid disease we advised an exploration of the right mastoid as offering the only chance, and that a poor one, of saving the boy's life. At 2.30 P.M. Mr. Romanis operated. There was a small area of diseased bone at the tip of the mastoid. The mastoid cells contained pus. The diseased mastoid was gouged away and the antrum was found full of pus. The antrum was irrigated with hydrogen peroxide, and the wound partly sutured, a gauze drain being inserted down to the antrum. The dura was not touched.

Recovery.—On the night of the operation the boy vomited twice, and not again. Pulse-rate and temperature began to fall at once (see chart); after 24 hours the gauze drain was

Chart of case of streptococcal meningitis showing fall of temperature after operation.

changed and the wound irrigated; these processes were continued daily until March 11th, when only a fine probe could be inserted. Knee-jerks began to return on Feb. 8th. The boy made an uninterrupted recovery and is about again. There is no impairment of mind, and at the time of writing his general health is better than it has been for a year. The condition of the right tympanic membrane is unchanged.

This was an undoubted case of generalised streptococcal meningitis, the organism being obtained in pure culture from the lumbar region of the cerebro-spinal canal. The meningitis was well established and the cerebro-spinal fluid only dripped slowly on lumbar puncture, both factors being said to increase the gravity of the prognosis. At operation the dura was not opened. The absence of signs of mastoid inflammation was rightly disregarded.

Balham, S.W.

A CASE OF SPONTANEOUS RUPTURE OF THE HEART.

BY R. LEONARD LEY, M.B., B.C.CAMB.,
ASSISTANT SURGEON, GREAT YARMOUTH HOSPITAL.

THE following case came under my notice recently, and seems worthy of record.

A married woman, aged 85, enjoyed good health for her age. On Feb. 2nd she told her son she was going out to collect her old age pension. He left the house at 4.40 P.M., when she had her things on ready to go out. He returned at 8.15 P.M., and found her lying in a heap in a corner of the room, dead. He called me in; I satisfied myself that she was dead and told him that I must inform the coroner.

At autopsy I found the body well nourished, with no marks of external violence. On opening the pericardium I found it distended with fluid blood and large clots. Altogether there must have been quite four ounces. On mopping up the fluid blood and removing the clots, I found nothing abnormal on the anterior surface of the heart, but on raising the apex and examining the posterior surface I found three vertical purple lines, the two external ones being nearly three-quarters of an inch, and the central one a quarter of an inch, in length. These on closer examination proved to be slit-like openings in the visceral pericardium. I then removed the heart. The aorta and aortic valves presented nothing of note, but on cutting into the heart muscle it proved to be extremely friable, and was greasy and fatty-looking. On cutting down to the apex of the left ventricle I found a dark clot firmly attached at a point near the septum and about one inch from the apex, corresponding to the openings on the posterior surface. Cutting into the muscle, after removing the clot and exposing the opening on the inner surface, I found minute clots in the substance of the heart wall. Evidently the inner wall ruptured first, and then the blood gradually dissected its way through the wall of the ventricle, finally bursting into the pericardium and causing death by pressure.

The predisposing cause here was, no doubt, old age and a fatty heart. There could hardly have been any great exertion. It seems doubtful even whether the old lady left the house.

Great Yarmouth.

A CASE OF TRAUMATIC RUPTURE OF THE AORTA.

BY P. ROWLAND KEMP, M.B., CH.B. EDIN.,
CASUALTY OFFICER, LONDON TEMPERANCE HOSPITAL, N.W.

THE following case is of sufficient interest to merit record.

On Jan. 17th, 1923, a male, aged 46, was admitted, dead, to the casualty department, with a history of having been struck on the head and chest by a portion of a stone fly-wheel which had separated while revolving at full speed in a motor works. He had a large abrasion over the sternum, an abrasion over the right malar bone, and an incised wound of the chin.

Post-mortem findings were as follows:—

Thorax.—An extravasation of blood into the subcutaneous tissues, and underlying the pectoralis major, in area of abrasion. An extravasation of blood into the anterior mediastinum. The sternum was fractured obliquely from above downwards and backwards at the level of the third to fourth costal cartilages. The lungs were deeply congested. The pericardium was greatly distended with blood which had escaped from a transverse tear of the aorta, just beyond the line of the aortic valve. The exuded serum was under considerable pressure.

Skull.—Beyond a firm adhesion of pia mater to dura over the upper part of the right posterior segment of the cerebrum, nothing abnormal was detected in the cranium.

For permission to publish the notes of this case I am indebted to Dr. H. H. Sanguinetti, pathologist to the London Temperance Hospital.

THE Cambridge University Press announce that they will publish "The Domain of Natural Science," by Prof. E. W. Hobson, Sc.D., LL.D., F.R.S., during the summer.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.—A meeting will be held to-day, Friday, May 11th, at 8.45 P.M., at the Miller General Hospital, Greenwich, London, S.E. The President, Dr. W. H. Payne, will take the chair.

Medical Societies.

OPHTHALMOLOGICAL SOCIETY: ANNUAL CONGRESS.

(Concluded from p. 899.)

Mr. D. V. GIRI contributed a paper on
*Intracapsular Extraction of Cataract, with Description
of a Simple Technique.*

It was based on 384 cataract operations he did at Bikaner, Rajputana, India. He had to resort to the intracapsular operation because his patients came long distances, were very poor, and time was of great value to them. One patient became so restless after the incision, and rolled his eye so much, that the operation could not be done step by step; hence the operation had to be done speedily, and he therefore expressed the lens in its capsule. Very little pressure was needed, and it came away without mishap. After that he proceeded deliberately to take out the cataract in toto. He described his procedure. The lids were best held apart and controlled by an assistant throughout the operation. For immature and intumescent cataracts the intracapsular was, he said, the operation par excellence. If capsulectomy was properly done, the mature hard cataracts shelled out easily as a whole. In a large percentage of mature and hard cataracts the capsulectomy operation gave results which compared favourably with the intracapsular. The worst cataracts to deal with were the hypermature and complicated. Mr. Giri discussed minutely every step of the procedure and compared it with other methods.

The Bowman Lecture was delivered by Prof. G. E. DE SCHWEINITZ (President of the American Medical Association). He took as his subject *Certain Ocular Aspects of Pituitary Body Disorders*, mainly *Exclusive of the Usual Central and Peripheral Hemioptic Field Defects*. (The Lecture was annotated last week, p. 912.)

Disorders of the Blood and their Ophthalmological Manifestations.

A discussion on this subject was held on April 27th. Sir HUMPHRY ROLLESTON, in opening the discussion, said that whereas patients with renal disease, arteriosclerosis, or affections of the central nervous system might first seek medical advice on account of ocular symptoms, and a diagnosis of underlying general disease might be made from the local changes, such was rarely the case in disorders of the blood. The disorders which he discussed were erythremia, pernicious anæmia, subacute combined degeneration of the spinal cord, aplastic anæmia, chlorosis, secondary anæmia (post-hæmorrhagic), splenic anæmia of adults and of infants, leukæmia (with chloroma), scurvy, purpura, hæmophilia. The underlying cause of erythremia was still a matter for further research; possibly it might prove to be a syndrome due to various causes. The frequency of ocular manifestations in it was as yet indeterminate. The visual disorders were variable, and could not be solely explained by the appearance of the fundus. In pernicious anæmia small retinal hæmorrhages were usually present; according to Cabot they occurred in over 70 per cent., and they were said to be seen when the red cells fell to 25 per cent. of the normal. In subacute combined degeneration of the cord the ocular manifestations were mainly those of anæmia—dimness of vision and pallor of the disc; also slight papilledema. There might be sluggishness, small size and inequality of the pupils, and nystagmus, owing to degeneration in the cervical cord. Retinal hæmorrhages and neuro-retinitis might occur in aplastic anæmia. In some of the cases of this now rare disease there was permanent impairment of vision. In severe secondary anæmia, hæmorrhages into the retina were very common, and this was probably chiefly due to the underlying toxæmia. In the chronic splenic anæmia of adults he did not know of

any special changes in the fundus. In the splenic anæmia of infants (Von Jaksch's anæmia pseudo-leukæmica infantum) retinal hæmorrhages probably occurred, but he could not state with what frequency. In Gaucher's disease the conjunctivæ showed a wedge-shaped thickening of brownish-yellow colour with its base to the cornea, first appearing on the nasal side of each eye. Foster Moore described three stages in the retinal changes accompanying leukæmia: (1) engorgement of the vessels, chiefly the veins; (2) the previous engorgement was accompanied by hæmorrhages having a central white spot, due to leucocytic accumulation; (3) a general leucocytic infiltration of the retina and choroid, causing thickening. Contraction of visual fields and night-blindness might also result in this disease. The visual symptoms were not of diagnostic importance in scurvy. Infantile scurvy might show petechiæ of the eyelids. In purpura flame-shaped hæmorrhages into the nerve-fibre layer of the retina were not uncommon, according to Foster Moore. In hæmophilia the retina may be free from hæmorrhages.

SIR FREDERICK ANDREWES, F.R.S., spoke on the pathology of disorders of the blood in relation to the eye. Functional disturbances of vision did not need much attention. When through heart failure or thrombosis the blood-supply to the retina was cut off or seriously reduced, vision might fail. In ordinary syncope temporary failure of sight might occur without structural change. Yet vision did not appear to fail in even the extreme degrees of pernicious anæmia; only in the post-hæmorrhagic form of anæmia did temporary blindness sometimes occur. Yet vision was commonly affected in the converse condition, erythræmia, in which the red cells and the total volume of blood were increased. Visible changes in the fundus took place as vascular alterations in blood conditions, and nowhere could the changes be so well studied. He believed that in chlorosis there was an increase in the fluid elements of the blood, and this was the only form of anæmia in which papilloedema had been observed to occur. He discussed oedema, extravasation of leucocytes, escape of red corpuscles, and leukæmia, remarking that it was possible the retinal hæmorrhages in the last-named depended in part on a weakening of the capillary wall from the emigration of leucocytes. He also entered into a minute consideration of the function of the blood platelets.

DR. A. J. BALLANTYNE said that more than 50 per cent. of the cases of anæmia and leukæmia he saw in nine years showed fundus changes of some kind, including alterations of the calibre, course and colour of the vessels, oedema of the retina, retinal hæmorrhages, and retinal exudates. In simple anæmias there was a tendency to broadening of both arteries and veins, also to an abnormal tortuosity. Pallor of the discs was often visible, but notable pallor of the fundi was exceptional. Hæmorrhages were never found in the retina when the hæmoglobin was higher than 35 per cent. Often the hæmorrhages and exudates cleared up when the patient was at rest in bed.

MR. R. R. JAMES said he had not seen fundus changes in chlorosis. He detailed the blood picture found in the various classes of cases he had examined during a period of 14 years' hospital observation.

DR. BALLANTYNE read a paper on Some Illustrations of Retinal Vascular Disease, and of Fundus Lesions in Diseases of the Blood.

MR. WILFRED TROTTER introduced a discussion on the *Diagnostic Significance of Proptosis*.

He said diagnosis was still essentially a clinical procedure carried out in the face of experience presented to the medical man unselected and at random. He intended to present in this paper only material which came directly within his own knowledge, restricting his consideration to the grosser forms of proptosis. A broad division of cases could be made according to whether the eye was displaced antero-posteriorly alone, or whether the antero-posterior projection was combined with some other

displacement. The first of these depended on swelling of the orbital tissues from inflammatory conditions or circulatory disturbance, the others to encroachment upon the orbital space by a swelling—generally a neoplasm—originating within or without it. The general surgeon mostly saw the first group in connexion with traumatic orbital hæmorrhage, thrombosis of the cavernous sinus, arterio-venous aneurysm within the skull, and Graves's disease. These he considered in detail. In the second group the cause at work was a swelling originating within or encroaching upon the orbit. The great point to determine was whether or not the cause was a malignant tumour. It usually was so when the eye was displaced forwards and also in the coronal plane. Such benign conditions, however, as mucocele of the accessory sinuses, exostosis of skull, and benign nasal growths could cause it. Malignant growths could be divided into those invading the orbit according to their place of origin, into those of ethmoid, sphenoid, and maxillary regions. Growths of the ethmoid and maxillary regions produced marked and early displacement in the coronal plane; growths of the sphenoid region tended to produce a downward and lateral displacement at a later stage. All these forms of malignant disease were of insidious onset, and often when their true nature was recognised they were beyond the hopeful reach of surgery. Growths of the ethmoid region were usually recognised by the rhinologist, in whose domain they came. Sometimes their course could be definitely delayed by operations which, at the time, appeared to be very unpromising. Growths in the sphenoidal region presented the greatest difficulties in early diagnosis; they were usually endotheliomata or sarcomata of the periosteal type. Sometimes they might be slowly developing for several years before causing unmistakable symptoms.

MR. J. H. FISHER gave a general review of the subject. The term "proptosis" directed attention to something retro-ocular which was propelling the eye forward, or, more correctly, a falling forward of the eye because it was imperfectly restrained in its orbit by muscles. The prominent eyes of very obese persons occasionally brought them within the title, and he had had to perform tarsorrhaphy for this condition; this possibility should be kept in mind in diagnosis. Foster Moore had found the fat in the orbit in Graves's disease to be in an abnormal condition; but Treacher Collins considered that Müller's muscle caused the condition, regarding it as the homologue of the "protrusio bulbi" muscle of lower animals. The proptosis in Graves's disease was not always symmetrical, nor of synchronous onset in both eyes. In both this disease and orbital tumours X rays were often of but little value. As removal of optic nerve tumours, whether with or without resection of the outer orbital wall, rarely left a passable cosmetic result, he strongly advised removal of the blind eye with the growth in every instance. Traumatic exophthalmia would depend on the presence of a foreign body lodged in the orbit, or the pressure of extravasated blood, or infiltration of the tissues with air through the fractured walls of the orbit from the nose or some of its accessory sinuses. Hæmorrhage into the orbit might occur without accident, such as in children suffering from whooping-cough or scurvy, in hæmophilics, and in later years of life it was attributable to arterio-sclerosis. Cysts following hæmorrhage had been described. Congenital dermoid was the most frequent cyst of the orbit; others included hydatid and cysticercus, but these could only be proved by examination after operation. Cellulitis and infective osteitis of the orbit were easy to diagnose. In all cases of proptosis with inflammatory manifestations examination should be made for paralysis of any of the nerves running in the floor or outer wall of the cavernous sinus. Vascular tumours of the orbit with proptosis must be differentiated into pulsatile and non-pulsatile, the latter being mostly cavernous angiomas. He advocated association with the neurologist in dealing with intracranial causes of proptosis; these he dealt with *seriatim*. Similarly, in cases of extension of growths from the

accessory sinuses of the nose, the assistance of the rhinologist might be needed in dealing with septic conditions in those cavities. The rhinologist invoked the aid of the radiologist, but both together often gave the ophthalmologist less assistance than he needed.

Dr. ANGUS MACGILLIVRAY said the apex of the cornea was between 12 and 14 mm. in front of the temporal margin of the bony orbit; when readings of over 14 mm. were taken, exophthalmos was present, when under 12 mm. enophthalmos. The routine use of the exophthalmometer was desirable. Proptosis due to increase in the orbital contents was the result of certain inflammatory, pathological, or traumatic conditions originating in the orbital cavity, such as periostitis, cellulitis, neoplasms, vascular derangements, and thickening of orbital walls. These were the main conditions causing proptosis which the ophthalmic surgeon was likely to be called upon to treat. He divided proptosis, for diagnostic purposes, into (a) bilateral, and (b) unilateral, the first being much the smaller division. He discussed them at length and said, in conclusion, that after 28 years of experience in the ophthalmic department of a large general hospital, he and his colleagues had come to regard proptosis as a danger signal, and the help of colleagues in other departments was sought without delay in arriving at a cause.

A Clinical Meeting.

In the afternoon a clinical meeting was held at London Hospital, where Mr. C. B. GOULDEN provided a series of cases for inspection and discussion.

Mr. W. T. HOLMES SPICER read a paper on Secondary Corneal Opacities.

Mr. F. A. WILLIAMSON-NOBLE read a paper on

Macular Changes Associated with Thrombosis of the Central Retinal Vein.

He described the appearances in four cases. In one case the sight of the patient, who was aged 27, had been failing 18 months before excision of the eye. There was old interstitial keratitis, the cornea being opaque and ectatic. He exhibited micro-photographs of sections cut at different levels. It showed the usual picture in venous thrombosis, and the thrombosis had occurred in the region of the lamina cribrosa. Sections of the half eye showed vascularisation of the middle and deeper layers of the cornea, and hæmorrhage in the nerve-fibre layer of the retina. There was slight oedema in the external molecular layer of the macular and perimacular region. He concluded (1) that in cases of thrombosis of the central retinal vein, a varying degree of oedema developed in the region surrounding the fovea, causing damage to retinal structures here; (2) that if oedema were of old standing or large in amount, some of the fluid percolated through the subretinal space, caused detachment of retina in the macular region, bringing about its degeneration.

Mr. F. A. ROSS and Dr. SHEPHEARD-WALWYN contributed a paper, illustrated by photographs, on a case of

Mikulicz's Disease.

The patient was a married woman, aged 37. The bulging below the eyebrow was found to be due to a finely-nodular enlarged lacrimal gland. There were the usual symptoms and physical characteristics of the disease. The urine was normal, and the W.R. negative. Immediately preceding death she had air-hunger, cyanosis, and oedema of both lungs, the physical cause of death being acute nephritis and uræmia. The tubules of the lacrimal gland, according to Dr. Canti's report, were normal, but were pressed apart by masses of round cells containing a few fibroblasts and fibrous tissue cells. The various treatments tried and the clinical course were carefully set forth.

A number of other contributions were also submitted.

Dr. MACGILLIVRAY read a paper on

Enucleation of the Eyeball under Local Anæsthesia.

He pointed out that the services of the expert anæsthetist were not always available, and in his absence

the administration might be indifferent. In the search for a suitable local anæsthetic, a 2 per cent. novocaine solution was fixed upon, owing to its comparatively low toxic properties, and in practice their confidence in it had increased. The solution consisted as follows: novocaine, 10 gr.; sodii chloridi, 2 gr.; potass. sulph., 1½ gr.; aq. destill., 3 l. It should be kept in a stoppered bottle, and could be sterilised more than once without deterioration if adrenalin were not added. He described the procedure in detail. It was not necessary to prepare the patient as for general anæsthesia. To neurotic or frightened patients two 5-gr. doses of veronal were given the previous day—i.e., at 5 and 10 P.M. The method could be easily adapted to all forms of extra-ocular operations. He believed that when once the details of the method of securing local anæsthesia had been properly grasped, it would become the routine, general anæsthetics being reserved for young children.

Microscopy of the Living Eye.

Mr. BASIL GRAVES described, with diagrams, the main principles of illumination of the eye, and discussed the selection of a suitable nomenclature for certain conceptions which, arising out of this new work, at present, he said, lacked suitable definitive terms. He felt that a vague, equivocal or unjustified use of certain terms was creeping into the English-written literature of the subject. Some of these terms had a very precise significance in the nomenclature of the physics of light, and he suggested that, for the present, the unsubstantiated appropriation of these was apt to lead to confusion amongst writers, and lacked scientific accuracy. He suggested certain non-committal terms (to indicate various clinical effects which he showed by diagrams). One of these was "relucency" for that property of a transparent living tissue in virtue of which a beam of light traversing it underwent modification to be revealed as a manifest illumination of the tissue. He demonstrated a small portable hand appliance to yield an intense beam 4 mm. in diameter, for use in inspecting the eye, or in such operations as needling, with the aid of which the operator could clearly see the membrane to be needled by taking his view through tissue whose transparency was not impaired by aberrant rays of light. He discussed the Zeiss binocular eye-microscope, and described means by which the optical system of its illuminator could be improved for practical routine work.

During the period covered by the Congress, an exhibition of instruments and appliances was held in the Marcus Beck Laboratory of the Royal Society of Medicine.

ROYAL SOCIETY OF MEDICINE.

SECTION OF OTOTOLOGY.

At a meeting of this section, held on April 20th, Sir CHARLES BALLANCE presiding, a discussion took place on the morbid anatomy and drainage of

Otitic Meningitis.

Mr. EDWARD D. DAVIS, who introduced the subject, based his remarks upon 13 autopsies and a number of specimens seen in London museums. Otitic meningitis of the middle fossa and cortex of the brain was, he said, much more frequent than that of the posterior fossa, and it was usually secondary to a temporo-sphenoidal abscess, or there was localised meningitis. In the 13 autopsies, thick gelatinous pus was always found in the cisterna interpeduncularis, and it extended thence into the subarachnoid space, along the large cerebral vessels. In front, the pus spread along the optic chiasma and anterior cerebral artery to the longitudinal fissure, to form a collection above the corpus callosum. More frequently, suppuration extended backwards by the posterior cerebral arteries and around the crura to form an abscess between the tentorium and the superior surface of the cerebellum. Collections of pus were present at the following situations: in the internal auditory meatus

and posterior surface of the petrous bone in front of the lateral sinus; in the cisterna interpeduncularis; between the tentorium and the superior surface of the cerebellum; and in the longitudinal fissure above the corpus callosum.

In order to demonstrate the paths of infection, a series of experiments were carried out on the cadaver, the subarachnoid space being injected with a solution of methylene blue passed through the internal ear and internal auditory meatus; and at a subsequent examination, when the skull cap had been removed, the methylene blue was found, in every case, in the cisterna interpeduncularis, extending to the optic chiasma, and backwards around the crura to the interval between tentorium and cerebellum, but no blue was present in the cisterna magna nor in the ventricles. And when the injection was made through the dura mater in front of the lateral sinus, to resemble infection by sinus phlebitis, the pigment was limited to the under surface and posterior aspect of the cerebellum, extending to the incisura posterior and the cisterna magna. A series of other tests led to the conclusion that repeated lumbar puncture during life did not increase the area of suppuration, and that lumbar puncture was inefficient as a method of drainage.

The research also seemed to justify the following conclusions:—

1. When the cisterna interpeduncularis or cisterna magna contained pus, efficient drainage was difficult. Hence to save life, early diagnosis was most important. An infection through sinus phlebitis gave an idea of a better prognosis than when through the internal ear.

2. When meningitis arose through the labyrinth, drainage and suction by a syringe through the internal auditory meatus was most likely to be successful.

3. If meningitis arose from sinus phlebitis, drainage and suction should be established both behind and in front of the lateral sinus; here an occipito-atlantal puncture might be useful.

4. Lumbar puncture was not a satisfactory drain for pus. It had been shown by experiment that if a bacteræmia was produced by the intravenous inoculation of *B. lactis aerogenes* or other organisms in animals a fatal meningitis was established by lumbar puncture or by the withdrawal of cerebro-spinal fluid; but meningitis did not occur in those septicæmic animals from which cerebro-spinal fluid was not withdrawn. This work suggested that G. J. Jenkins was right when he said that the smallest quantity of cerebro-spinal fluid necessary for diagnosis should be withdrawn.

Mr. J. F. O'MALLEY asked what set of symptoms would induce Mr. Davis to open direct through the labyrinth, or to put a drain in the wall of the antrum, in front of the lateral sinus.

Mr. T. B. LAYTON said this contribution seemed to show that lumbar puncture should only be done after due care and consideration, as it was not wholly free from danger.

The PRESIDENT said the importance of this subject lay in the fact that the treatment of such cases was a matter of life and death. He had known sudden death occur from lumbar puncture. A vital point was whether organisms were present in the cerebro-spinal fluid or not. Sometimes he had found that the milky condition of the fluid was due simply to the presence of cells, not micro-organisms. If no organisms were in the cerebro-spinal fluid, the patient would very probably recover. There was no doubt that the only treatment of these cases was by operation; but it should be done, if possible, within a short time of what appeared to be the onset of the meningitis. The usual hospital experience, however, was that cases were seen too late. He did not agree that occipito-atlantal puncture should replace drainage. The important requirement was some means of reducing the pressure of fluid in the great cerebellar cistern.

Mr. DAVIS, in reply, said occipito-atlantal puncture was now frequently done in America, particularly for spinal tumours, and he thought it might be useful instead of Haynes's operation. When it was considered that a patient had meningitis arising from labyrinthitis drainage should be done through the internal auditory meatus and the labyrinth.

Complete Deafness after a Fall.

Sir JAMES DUNDAS-GRANT showed a man, aged 48, who 3½ years ago became quite deaf after falling on to his feet from a height of 6 ft. He did not strike his head, but during several days he had pain in his neck. During the night he had diarrhoea and vomiting and next morning he was deaf. The tests which were carried out suggested concussion of both labyrinths. A variation in symptoms showed there was a functional element in the case. He also showed a patient, a lady aged 29, whose deafness was much increased by a fall.

Mr. F. J. CLEMINSON related a case in which a man, when sleeping in the saloon of a steamer, was struck on the head by a large slab of marble, producing not only traumatic neurasthenia, but also considerable deafness in both ears, which the tests seemed to show was nerve deafness.

Mr. O'MALLEY referred to a case he had of sudden deafness without a precedent injury. He had her vestibular reaction tested, and there was a good response. He could not understand how the deafness had occurred. He thought the second patient of Sir James Dundas-Grant had otosclerosis.

Mr. DAVIS said that during the war he saw several cases of injury—by bullet or shrapnel—in the region of the mastoid process. They never made any recovery, but remained very deaf. The ordinary concussion case, such as that due to a cab injury, resulting in deafness, did have improvement of hearing. If hearing in any case did not improve in six weeks he concluded that deafness was permanent, and he asked whether that was the general view.

Sir JAMES DUNDAS-GRANT, in reply, pointed out that a heavy fall on the feet sometimes caused a fracture at the base of the skull. And such a fall might damage such a delicate organ as the ear even if the force was not sufficient to fracture the skull. In some of the mastoid cases he thought there was a fracture of the internal ear, or it might be so violently disturbed that it became thereafter peculiarly sensitive and might be completely destroyed by hæmorrhage into it. He agreed that if no improvement of hearing occurred in six months something more than mere concussion was present.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SURGICAL SECTION.

A MEETING of this section was held on April 27th at the Royal College of Surgeons in Ireland, Sir WILLIAM WHEELER in the chair.

Exhibition of Cases and Specimens.

Mr. A. K. HENRY showed a needle for ligature of the middle meningeal artery in gasserian operations.—Mr. A. A. McCONNELL said that he had used this needle, and he thought it an extremely useful instrument.

Mr. R. A. STONEY showed a urinary calculus from a man aged 33, who had had pain in his back for about three years. At the beginning of the attack for which he came into hospital, he had hæmaturia, lasting for about ten days. X rays showed a large dense shadow in the renal area; a second X ray showed the same shadow. Pyelo-lithotomy was performed and the pelvis sutured. There was practically no discharge from the wound, but on the fourth day a considerable amount of blood was present in the urine. This lasted for about a week and then cleared up. After three weeks the patient left hospital and had since remained perfectly well.

The PRESIDENT showed a specimen (with X ray photographs) of total gastrectomy for precancerous ulcer of the stomach. The patient was a woman aged 60, who had a history pointing to a gross gastric lesion for about 14 months. A gastric ulcer was tentatively diagnosed, but was not definitely confirmed.

after X ray examination. On opening the abdomen a deeply excavated ulcer, about the size of a shilling, was discovered on the posterior wall at the cardiac end. The edges were raised and hard, and the glands around the lesser curvature were enlarged. The age of the patient, the induration of the ulcer, and the nature of the glands suggested that malignant change had taken place, and, in any event, it was felt that such an ulcer in an elderly woman should be considered precancerous. Total gastrectomy was performed and Sir William Wheeler pointed out the use of De Martel's clamps in overcoming the technical difficulties of the operation. Microscopical sections showed no evidence that any malignant change had yet taken place. The patient made an admirable recovery and now prefers solid to liquid food.

Dr. T. G. HARDMAN, who had X rayed this patient, showed films. When an opaque meal was given to the patient a very definite filling effect was shown on the lesser curvature in the recumbent position, but was not present when the patient was in the upright position. Consequently a tentative and not an absolute diagnosis of ulcer was made.

Mr. H. STOKES did not think the President could have done anything but total gastrectomy in this case and Mr. W. PEARSON agreed with this opinion.

Dr. H. B. GOULDING asked how long it was since the operation had been performed and whether the patient was losing or gaining weight.

Mr. C. J. MACAULEY said he thought unless one was absolutely convinced that the ulcer was malignant it was too radical to take out the whole stomach.

The PRESIDENT briefly replied.

Mr. McCONNELL described the technique of colopecty.

Miss K. PORTLEY reported a case of

Ascaris Appendicitis.

The patient, a boy, was admitted as a case of acute appendicitis. At operation the mesentery of the ileo-cæcal junction was studded with tubercles with a slight amount of pus in the right iliac fossa. A worm about six inches in length, of the *Ascaris lumbricoides* type, was found free in the peritoneal cavity. The ascaris had apparently made its exit from the alimentary canal by perforating the tip of the appendix. Miss Portley reviewed the literature of appendicitis arising from infection parasites, and stated that she could find no mention of the ascaris.

Mr. W. DOOLIN read a paper on

Intestinal Occlusion in Tuberculous Peritonitis.

A young motor mechanic was admitted to St. Vincent's with symptoms suggestive of subacute sigmoid obstruction. Laparotomy disclosed widespread miliary peritoneal tuberculosis of the adhesive type, too extensive to warrant resection of the ileo-cæcal segment, which was apparently the primary focus of the disease. After a period of seven weeks' post-operative X ray therapy the patient was sufficiently recovered to leave hospital for sanatorium treatment. Prognosis in this type of case might be looked on as serious. The simulation of the "acute abdomen" by acute peritoneal tuberculosis was rare, though a few references were to be found in French and American surgical literature.

SECTION OF PATHOLOGY.

A meeting of this section was held on April 20th. Dr. W. D. O'KELLY, the President, was in the chair.

Dr. W. BOXWELL described a case of

Brain Sarcoma.

The patient, a boy $4\frac{1}{2}$ years, was admitted to hospital suffering from convulsions. He recovered after a hot bath, but a later attack had to be treated with chloroform. Previous to the convulsions he had been lively, talkative, and precocious. While in hospital he vomited solid food, and had severe headaches. He answered questions intelligently, but his cerebration and reaction time were slow. Pulse 90, B.P. 80, T. normal. The cerebro-spinal fluid was under considerable pressure, but contained no cells. He died

after eight weeks in hospital, having become blind before his death. The brain showed an extensive cellular infiltration extending under the pia; this consisted of round cells apparently sarcomatous; he believed that he could trace their origin from the choroid plexus of the fourth ventricle.

Mr. T. T. O'FARRELL could see no connexion between the small tumour in the roof of the fourth ventricle and the main tumour; he asked whether the question of chloroma had been considered.—Dr. J. T. WIGHAM said that the tumour might easily be endothelial in origin, although the cells were like those of a round-cell sarcoma.—Dr. BOXWELL, in reply, said that the tumour was perfectly white in colour.

Sir JOHN MOORE read notes on

Two Cases with Unusual Sequelæ.

The first was a case of pneumonia in a girl, aged 18, admitted to hospital on Jan. 1st after five weeks' illness from what was stated to be pneumonia. She was thin and pale, had a persistent cough, and abundant sputum. The sputum was examined three times for tubercle bacilli with negative results; a Widal test was also negative. An exploratory puncture in the dull area over the base of the left lung was made twice, but without tapping any collection of fluid. The liver was greatly enlarged. Towards the end of January the patient's condition became critical. The lower limbs became anasarcaous, and severe pain set in in the right thigh, apparently due to thrombosis, which finally extended up to the inferior vena cava. The breath and sputum were foetid. On Feb. 20th a pleural friction rub was detected over the base of the right lung. Temperature became subnormal on the 24th and remained so till death on the 27th. Post-mortem findings were: abscesses in liver, spleen, left perinephric region, and lower lobe left lung. (Esophagus, liver, left lung, left kidney, all adherent to diaphragm. Pus from the liver abscess contained long chains of streptococci. Tubercles were found in the liver, which was extensively infiltrated with fat.

The second patient, a woman aged 56, was admitted to hospital on March 3rd, extremely emaciated, and wearing a look of great physical suffering. She had had for nearly a year gnawing pains over the upper part of the abdomen, which was very tender on pressure. She was also suffering from loss of appetite, vomiting, and constipation. She was losing flesh rapidly, and during the first nine days in hospital she lost 2 lb. Any attempt to take food brought on sickness, and she vomited frothy stuff, and on two occasions blood. Her pulse-rate was persistently quick—100 to 120, respirations 24 to 26, and temperature usually subnormal. On examination a tumour in the lower part of the epigastrium near the middle line was found, and enlargement with hardness of the inguinal glands. A diagnosis of carcinoma of the stomach was made, and the case was pronounced to be inoperable; a screen examination confirmed the diagnosis. The patient lived until March 25th, when she collapsed suddenly and died quickly of hæmorrhage into the stomach. Post-mortem findings: When the peritoneal cavity was opened, there was an escape of a large quantity of clear, straw-coloured fluid. The falciform ligament was greatly thickened, and was hard and nodular. The gall-bladder was adherent to the duodenum. The pyloric end of the stomach was firmly bound down by dense adhesions. The spleen was closely adherent to the greater curvature of the stomach. The peritoneum had a number of nodules scattered over it, and there were several enlarged, hard glands in the mesocolon. The liver was rather small, but showed no secondary nodules. The stomach was small; the wall was hard and thickened. When opened, the stomach was found to be full of blood. In the posterior wall, near the pylorus, was a large crater-like ulcer, with a fungating growth in the centre of it. The diaphragm was studded throughout with secondary growths, some of which were the size of a shilling.

Dr. BAREND VIVIER demonstrated the specimens. There were two abscesses in the first case, one in the liver and the other in the base of the left lung penetrating the diaphragm and involving the spleen and left kidney.

Dr. O'FARRELL said that he would like to ask what the origin of the sepsis in the first case was, and if a blood culture had been taken. He would also like to know if the œsophagus was quite normal. Sometimes foreign bodies were found in the œsophagus, and gave rise to conditions like those described. It would be interesting to know what the source of infection in this case was, and if it was a primary focus.

The PRESIDENT said that, regarding the first case, he was satisfied that there was no tuberculous lesion in the lungs, and he was inclined to think that this

was not an ordinary case of tuberculosis, on account of the absence of tubercle bacilli in the sputum, but that the tubercles in the liver were a subsidiary chance infection. The second case was extremely interesting. He thought that hæmorrhage in such a case was uncommon. The freedom of the liver from any growth was a point of importance.

Mr. HENRY STOKES said that, regarding the first case, before the needle was put into the patient's chest she was X rayed. There was at that time no pleural effusion, and, according to the X rays, any abscess must have been small. It had certainly not penetrated the diaphragm.

Sir JOHN MOORE, in replying, said that in the first case no blood culture had been made. He had not looked for any evidence of actinomycosis. He was of opinion that this was really originally a case of pneumonia, and that the infection took its origin in a very seriously damaged left lung. Regarding the second case, he looked upon it as undoubtedly one of ulceration of the stomach, and he thought that this accounted for the illness up to a comparatively short time before death. The fact that cancer of the stomach might supervene on an ulcer was demonstrated in this case.

Dr. O'FARRELL read notes on cases of cylindroma of parotid region, adenosarcoma of kidney, and basal cell cancer of neck.

Reviews and Notices of Books.

CLINICAL PATHOLOGY.

Clinical Laboratory Diagnosis. By ROGER SYLVESTER MORRIS, A.B., M.D., Professor of Medicine in the University of Cincinnati. London and New York: D. Appleton and Co. 1923. Pp. 456. 25s.

THIS book is designed to bring under one cover all the laboratory methods which may be of use in the investigation of cases. In the compiling of such a manual the author is faced, first, with the problem of the arrangement of his matter, and then with that of selection and rejection among the multifarious procedures of clinical pathology, bacteriology, and chemistry. The matter of the present volume is arranged under nine heads—Fæces, Blood, Urine, and so forth—each dealing with one particular sort of material for examination. This arrangement makes for ease in the location of any desired procedure, but is purely arbitrary and tends to result in a sacrifice of a proper understanding of the principles underlying any particular line of investigation to a certain rule-of-thumb facility. In his solution of the problem of what to omit and what to include the author has for the most part shown judgment, but some method of estimating renal function in addition to the pthalein test of Rowntree and Geraghty might well have found a place; and it is surprising to find no reference to the fat-fatty acid ratio in the fæces as a help in the diagnosis of pancreatic disease. Space might well have been saved by the omission of details of a number of procedures of doubtful value. Ehrlich's diazo-test, for instance, has not much place in modern medicine, and in the present state of knowledge little useful clinical information can be derived from the estimation of the cholesterol, fatty acids, or amino-acids of the blood. Details of the technique of these procedures have no place in a clinical manual. In the section on blood no satisfactory criteria are given for the differentiation of large lymphocytes, large "mononuclears" and "transitionals"; as such do not exist, this is hardly surprising, but the author might have saved the conscientious student a lot of worry by saying so. The sections on parasitology are full and contain much useful matter. The chemistry of the blood is dealt with by Drs. Raphael Isaacs and David S. Hachen. Ample details of the technique of all the procedures described are given.

An excellent feature of the book is the multiplicity of references—a less satisfactory one is that few of the illustrations are original.

Clinical Laboratory Methods. By RUSSELL LANDRAM HADEN, M.A., M.D., Associate Professor of Medicine, University of Kansas, School of Medicine, Kansas City, Kansas. London: Henry Kimpton. 1923. Pp. 294. 18s.

THIS volume covers the whole range of clinical laboratory technique. The author aims at providing well-trying methods; and, where possible, he reduces the procedure to a single test; with the result that, for the ground covered, a valuable volume has been produced in the minimum of space. The one disadvantage to readers here is that the methods recommended may not be those which, by common use, have become well established in this country. The usual routine of laboratory work, both pathological and bacteriological, has been included, and of the tests recommended both the procedure and the preparation of the necessary solutions are given together. The book contains an account of new work in biochemistry and the section on the quantitative chemical examination of the blood is very complete in this respect. A special feature is the chapter on Miscellaneous Clinical Pathological Examinations, and that on Chemical Procedures and Solutions; dealing among other things, with the use of the colorimeter and nephelometer, the preparation of volumetric solutions, the calibration of volumetric apparatus, and the colorimetric determination of the H-ion concentration of biological fluids. While it is probable that the clinical value of some of the elaborate technique recommended has yet to be established, Dr. Haden has nevertheless compiled a comprehensive and practical volume appealing both to the advanced student and the beginner in laboratory work.

The volume is of a convenient laboratory size and is well printed; illustrating the text are fine colour plates and 69 photographs and diagrams.

THE PIRQUET SYSTEM OF INFANT FEEDING.

Die Ernährung gesunder und kranker Kinder. By Dr. EDMUND NOBEL, Universitäts-Kinderklinik, Vienna. Vienna, Leipzig, Munich: Rikola. 1923. Pp. 74.

ALTHOUGH the Pirquet system of infant feeding upon which this book is based has gained few adherents in this country, yet Dr. Nobel has much to say that is of more than local interest. The book is divided into two parts, dealing respectively with theory and practice. In the first the principles of the *nem* system—the word *nem*, denoting 1 g. of standard breast-milk, being formed from the initial letters of the three words Nahrungs-Einheit-Milch—are set out with conspicuous clearness. Some of the points upon which stress is laid are those emphasised by our own pædiatrists, such as the need of absolute regularity in feeding and the regulation of the quantity of food according to the size and weight of the infant. The estimation of the exact quantity of food needed in a given case is obtained by Pirquet's *pelidisi* formula (*pelidisi* being derived from *pondus decies linearis divisum sedentis altitudine*), which is expressed as the cube root of ten times the weight divided by the sitting height, and in a normally developed infant is of the value of 100. The case for the Pirquet system with its rather forbidding nomenclature, is well set out; but the system suffers from at least two serious defects. First, the inadequate recognition accorded to the temperamental factor—an active, lively baby obviously needs more nourishment than a phlegmatic infant, even where the *pelidisi* index is the same. Secondly, save that the optimum protein-percentage is stated to be one-tenth of the total *nem* value, as in the case in breast-milk, and that a fat content in the diet amounting to at least 10 per cent. of the total food value is recommended, the question of balance in the food elements is practically ignored. After

careful study of the book it is still difficult to see in what respects the Pirquet system is an improvement upon the simpler calorie system.

The practical section of the book will have more interest for English readers. After a few remarks on the food requirements of the pregnant and nursing woman, Dr. Nobel details an excellent scheme for the feeding of healthy children from the first day of life until the end of the first year, the scheme being drawn up on the lines followed at the Kinderklinik in Vienna. For the first two weeks six to seven breast-feeds are given at three-hourly intervals during the 24 hours, the 3 A.M. feed being dropped after the third week. During the fifth month the child learns to drink from a spoon, a feed of milk broth being substituted for the mid-day breast-feed, while in the sixth month two such feeds are given. During the second half-year the child gradually learns to eat vegetables, stewed fruit, and biscuits, in addition to the four breast-feeds which are given daily till the end of the ninth month. Where, in the case of artificial feeding the quality of the cows' milk leaves something to be desired, the daily administration of lemon juice, and, in winter, of a small quantity of cod-liver oil, is recommended, emphasis being laid throughout on the value of the accessory factors in the diet. A number of useful recipes for preparing vegetable and other broths are given. The final chapters of the book are devoted to a discussion of the nourishment of sick children and to various arithmetical calculations.

Dr. Nobel's book is interesting and well written, and will repay careful study.

OPHTHALMOLOGY.

Diseases of the Eye. Fourth edition. By Sir JOHN HERBERT PARSONS, C.B.E., D.Sc., F.R.C.S., F.R.S., Ophthalmic Surgeon, University College Hospital; Surgeon, Royal London (Moorfields) Hospital. London: J. and A. Churchill. 1923. With 21 plates and 326 text-figures. Pp. 660. 19s.

This is emphatically a student's text-book, covering the whole ground of ophthalmology with no superfluous matter. It differs from larger text-books such as that of Fuchs in omitting all reference to some of the rarer diseases of the eye and in cutting down discussion of the subjects dealt with to what the author considers essential. It is therefore necessarily somewhat dogmatic, but this, from the student's point of view, is advantageous. To have mastered the contents of this book is to have been in close contact with a first-rate teacher and ophthalmologist, and even if the future ophthalmic surgeon finds occasion to modify the knowledge gained from it in particular points, he will certainly never regret having pinned his faith to it as a sound foundation on which to build. We would especially pick out for commendation the chapters on diseases of the fundus oculi. The varieties of fundus disease actually seen in the out-patient room are so many that the student deserves rather more information about them than he is vouchsafed in most text-books, and here he gets it, though we are sure that the author himself would be the last to claim that it is anything like exhaustive.

The diagrams and plates illustrating both the ophthalmoscopic appearances and the pathology of different forms of retinitis may be specially commended. The disease generally called "retinitis pigmentosa" is characterised by the author as "an extremely chronic, progressive degeneration of the choroid in both eyes." In this description he differs from the older authorities, and other points might be cited in which all might not agree with him—for instance, his advocacy of tenotomy in small degrees of squint and the somewhat half-hearted way in which he mentions antisyphilitic remedies in the treatment of interstitial keratitis. A feature quite new in this edition is a short section on preventive ophthalmology. In the chapter on the causes and prevention of blindness large use is made of Mr. Bishop Harman's evidence before the Advisory

Committee on the Welfare of the Blind. Under the heading "Hygiene of Vision," the subject of illumination is discussed.

That this edition will maintain the popularity of this book need not be doubted.

Text-book of Ophthalmology. By HOFERAT ERNST FUCHS, formerly Professor of Ophthalmology in the University of Vienna. Authorised translation from the twelfth German edition. By ALEXANDER DUANE, M.D., Surgeon Emeritus, Knapp Memorial Hospital, New York. Seventh edition, revised and reset. London and Philadelphia: J. B. Lippincott Company. 1923. With 455 illustrations. Pp. 997. 42s.

To the majority of English-speaking students of ophthalmology this is probably still the best-known text-book of the subject on a large scale that exists, though in recent years it has had to compete with others of a similar size. In previous English editions of the Fuchs text-book the translator and editor has modestly kept his own supplementary contributions confined within brackets. In the present edition he has not only done away with the brackets, but by rearranging the whole of the subject-matter and rewriting a great part of it has produced what is practically a new book. In so doing, he tells us, he has had the benefit of consultation with Dr. Fuchs and of comparison with the thoroughly revised thirteenth German edition just prepared by Prof. Salzmann. He has, we think wisely, omitted a considerable amount of non-essential matter which appeared in former editions, so that in spite of a great deal that is new the total bulk of the new volume is less by 70 pages than that of the sixth edition. As an instance of omission we may mention the explanations of the Young-Helmholtz and the Hering theories of colour vision, which no longer appear, while the additions to the text are far too numerous to mention. One of the most important is a fuller treatment of the perimetry of glaucoma. Even the chapter on motor anomalies of the eye, which in the sixth edition was largely the work of the translator, has been re-written. The sections on the anatomy of the eye are now grouped together so as to form the initial part of the book. The final part on the operative surgery of the eye is kept nearer to its previous form than most other portions of the book, though it is not without additions, as, for instance, a reference to epithelial inlays for contracted socket and outlays for lid operations, and a diagrammatic representation of the area laid bare by the conjunctivo-corneal flap of Elliot in his trephining operation. As, however, the descriptions of various operations are necessarily abridged it would add to the value of the book were references given to fuller accounts of some of them.

As a whole this new edition of a great work embodies a noble effort to retain its place as the premier text-book of ophthalmology.

PRACTICAL APPLICATIONS OF X RAYS.

By G. W. C. KAYE, O.B.E., M.A., D.Sc., A.R.C.Sc., F.Inst.P., Head of the Radiology Department, the National Physical Laboratory; President of the Röntgen Society. London: Chapman and Hall, Ltd. Pp. 135. 10s. 6d.

THIS book is based largely on a course of Cantor lectures delivered by the author before the Royal Society of Arts in 1921. Its main concern is with the practical uses of X rays. The first 72 pages are devoted to a succinct account of X rays and their physical properties, the different types of X ray tubes in current practice, the apparatus required for their excitation, and the methods used for measuring the wave-lengths and the intensities of beams of X rays. There is then a chapter of six pages upon the medical applications of X rays, followed by an account of some of the industrial uses to which the rays have been put. The most important of these may perhaps be said to be the examination of materials for the purpose of revealing flaws in structure and in

handiwork, notably in metals and timber, especially aeroplane parts, and in the detection of the work of the impostor in works of art. The volume is completed by three appendices, one on the report of the X Ray and Radium Protection Committee, one on X ray and electro-medical nomenclature, and one on atomic numbers.

The book is well illustrated by a number of line drawings and reproductions from original radiographs.

PRACTICAL PHYSICS.

By J. A. CROWTHER, Sc.D., F.Inst.P., sometime Fellow of St. John's College, Cambridge; Demonstrator of Physics in the Cavendish Laboratory; University Lecturer in Physics as applied to Medical Radiology, Cambridge. Oxford Medical Publications. London: Henry Frowde and Hodder and Stoughton. 1923. Pp. 260. 10s. 6d.

THIS book on practical physics follows the general scope of the well-known Manual of Physics by the same author, and maintains the standard which this book has set in mode of presentation and in the help which it affords to the student in the more difficult parts of the subject. Dr. Crowther's foreword to the student, beginning with "To err is human," should do something towards reconciling the latter to the methods of exact measurement which are the main substance of the book. The scope of the subject is conditioned by the scope of the syllabus for the first medical examination, and however desirable it may be for the student to get familiar experimentally with forms of radiation other than light and heat, it is hardly justifiable for teachers to introduce the matter into their first medical courses. Probably Dr. Crowther has omitted these subjects for this reason.

If it be granted, and there are some teachers who will dissent, that text-books are required for the practical work entailed in a course of elementary physics, then it will be agreed that Dr. Crowther's book is likely to serve this purpose well. It is well illustrated by good line drawings, which enhance its value.

THE HOME AND HEALTH IN INDIA AND THE TROPICAL COLONIES.

By KATE PLATT, M.D., B.S. Lond., formerly Principal, Lady Hardinge Medical College and Hospital for Women, Delhi, India. London: Baillière, Tindall and Cox. 1923. Pp. 216. 5s.

A PLEASANTLY discursive little book, which will be appreciated by all women about to make their home in India. Dr. Platt has had the advantage of long residence in various parts of India in a capacity of teacher and medical adviser, and is thus in a position to supply information, friendly caution, and reassurance where these are most needed. Part I., entitled Making the Home, will be found of especial value, as though Parts II. and III., which are headed About the Nursery and Tropical Diseases, respectively, are readable enough, they deal sketchily and somewhat dogmatically with a great variety of topics, some of which cannot properly be disposed of in a few lines. Too little stress is laid on the need for ante-natal care and supervision, a subject which might well be developed in future editions.

Dr. Platt's book contains sound common-sense and should do much to encourage those women setting out to begin life under new conditions.

JOURNALS.

BRAIN. Vol. XLV., Parts 3 and 4.—Two Cases of Syringomyelia and Syringobulbia, Observed Clinically over Many Years and Examined Pathologically, by James Taylor, J. G. Greenfield, and J. P. Martin. Of the two cases recorded one had been observed continuously for 24 and the other for 19 years. The clinical course of the two cases was entirely different; in the one, the symptoms showed no change from the time the man first came under observation, while in the other the disease was throughout steadily progressive. Post mortem, the most striking contrast

was the inverse relationship of the cavitation to the process of gliosis. In the first case there was much more gliosis than cavitation, and it is suggested that the fluid within the cord had formed a channel by which it could escape into the subarachnoid space, and that the formation of this channel coincided with the arrest in the progress of the disease. More important than the increase of fluid within the cord as an ætiological factor may be a congenital instability of the glial tissue in the regions which the central canal of the cord occupies during foetal life.—A Study of the Cerebral Fibre Systems by means of a New Modification of Anatomical Methods; The Lateral Wall of the Thalamus and the Sagittal Portion of its Cerebral Fibre System, by Joshua Rosett. The author is of the opinion that careful dissection of properly hardened tissue, although the oldest, still remains one of the best methods at the disposal of the anatomist. His new method consists of two processes: (1) longitudinal sectioning; and (2) serial dissections. By the former it is possible to produce longitudinal sections of strands of tissue 10 cm. long, 3 or 4 mm. in width, and less than 1 mm. in thickness. The course of the fibre tracts may thus be observed in the two possible directions on a plane surface, the third direction may be supplied by serial dissections. In these, after the tissue has been hardened it is dissected and a record of each step in the dissection is obtained by pouring on the preparation molten wax, which furnishes a mould into which is poured plaster of Paris. The lateral wall of the thalamus has been examined by these methods, and the author correlates his findings with those of previous anatomists.—A New Conception of the Elements of Sensation, by John S. B. Stopford. Fifty-one patients were examined in whom it was known that a complete division of definite peripheral nerves of the upper extremity existed. The author holds that in the past anatomists have designated nerves as purely cutaneous on insufficient evidence, and therefore it would appear that any division of sensation into cutaneous and deep must be regarded as artificial, and apt to be misleading when applied to clinical work. He finds that the various forms of sensation included under the division of deep sensibility may be dissociated; and that therefore deep sensibility ought to have been subdivided, just as cutaneous sensation has been divided, into epicritic and protopathic. Contrary to the general belief that the earlier return of protopathic sensibility is dependent upon a more rapid rate of regeneration in protopathic than epicritic fibres, the author holds that it is more reasonable to expect to find an explanation of the two stages of recovery in the central nervous system, rather than to find it due to a different rate of regeneration of two sets of fibres which anatomically appear to be identical. The fact that the forms of sensation appearing late are those which Head has proved to have cortical representation is significant.—Toxic Polyneuritis, by Wilfred Harris. A comprehensive review of the less common forms of toxic polyneuritis including leukæmic, relapsing, and hæmatoporphyriuric.—On Muscle Tonus, by J. W. Langelaan. This paper gives the results observed in frogs after: (1) the seventh, eighth, and ninth rami communicantes were divided on the right side; (2) the same posterior roots were cut; (3) the spinal cord had been divided between the second and third spinal roots with subsequent section of the seventh, eighth, and ninth rami communicantes; (4) the spinal cord was only partially cut, and a new scheme of the primary spinal reflex arcs based upon these results is suggested.—The Central Connection of the Vestibular Nuclei with the Corpus Striatum, and their Significance for Ocular Movements and for Locomotion, by L. J. J. Muskens. On experimental evidence the author believes that the tertiary vestibular tracts terminate in the oral part of the globus pallidus and that the secondary vestibular tracts which ascend in the posterior longitudinal bundles cross the middle line by way of the posterior commissure before entering the commissural nuclei.

THE LANCET.

LONDON: SATURDAY, MAY 12, 1923.

THE MENTAL TREATMENT BILL.

SINCE the repeated reference, in an open letter¹ to visiting committees of mental hospitals from the chairman of the Board of Control, Sir FREDERICK WILLIS, to an impending Mental Treatment Bill, its formal introduction has been awaited with interest. Lord ONSLOW moved the second reading of the Bill in the House of Lords on May 3rd in a forcible address which left no doubt as to the main point on which new legislation is required. The chief purpose of the Bill is to provide that a patient suffering from incipient mental disorder may be received in recognised public or private institutions for treatment without the stigma of certification. The present provision for voluntary boarders in private licensed houses does not meet the whole need, for not only is such treatment beyond the reach of the poor, but it cannot be applied to those sufferers from incipient mental disease who may be incapable of volition just at a time when their immediate removal to an institution might very well be the only treatment likely to effect a permanent cure. The safeguards to prevent abuse of the new powers are well planned. The recommendation of two doctors—one at least being a medical man approved by the Board of Control—must be countersigned by a justice of the peace or a minister of religion, personally acquainted with the patient, who is satisfied that the patient is incapable of voluntary action at the time. The limitation of uncertified treatment to a maximum period of one year in all is another wise provision. If one year's treatment does not avail it is probable that certification in any case be inevitable.

There will be three ways of egress for the uncertified patient from an institution to which he may have been sent when incapable of understanding his position: (1) he may leave the institution at any time on giving 48 hours' notice; he may be discharged (2) by the superintendent or (3) by the Board of Control, which will frequently inspect institutions housing uncertified patients. The mechanism of the scheme is elastic. County and borough councils, acting through their visiting committees, will be able to receive patients into their own institutions or may arrange for general hospitals to receive early mental cases. The advantages of this latter provision include, from the patients' point of view, separation of non-certified from certified patients, and access to special facilities for diagnosis and treatment of physical disease; and from the communal aspect, the educational value to medical students and nurses of the study of border-line cases. Out-patient departments, where cases of nervous or of mental disease will not obviously be differentiated, are to be allowed, and many relatives doubtless will take advantage of this method of procuring early medical advice without upsetting the patient. Adequate provision for after-care will now be part of the business of visiting committees, while opportunity will be given for more lavish expenditure of public money on coördinated research. The constitution of the visiting committees will be strengthened by

the power to coöpt expert opinion among their members and also to obtain the services of men or women, not necessarily members of the county or borough council, who may have leisure and a desire to devote it to visiting the insane.

There remains only the question of adequate central control. The existing staff of Commissioners in Lunacy, of which six only as doctors or lawyers are in a position to pay statutory visits, cannot cope with its present work, let alone the inevitable extra burdens of inspection that this Bill must carry with it. It is suggested that instead of still further increasing the number of Commissioners, whose salaries are £1200 to £1500, an increase in the number of medical inspectors, at £500 to £800, would be a more economical and practical method of achieving proper supervision, and in the future it will be permissible for certain visits and local work to be carried out by inspectors. Lord ONSLOW'S Bill should meet with little criticism as to its essential points, and its embodiment in our statutes may well prove a landmark in the development of the therapeutics of mental disease.

A NEW THEORY OF COAL-MINERS' NYSTAGMUS.

WE have received an advance copy of a paper by Dr. FREDERICK ROBSON on miners' nystagmus, the first half of which was read at Cardiff on March 22nd before the South Wales Institute of Engineers, followed by a discussion in which many medical men took part, and the second half read at Swansea on April 27th. In it the author propounds a new theory of the causation of the disease, which, if true, would entirely upset the conclusion arrived at two years ago by the Nystagmus Committee of the Medical Research Council, supported by the opinion of most of the medical men who gave evidence and had practical experience of the subject—viz., that the chief factor in its causation is deficient lighting. Dr. ROBSON'S theory is that the main cause of miners' nystagmus is the emanation of noxious gases from recently cut coal. His argument is that nystagmus may be due to anoxæmia, that carbon monoxide can produce anoxæmia, that carbon monoxide is present as a constituent of occluded gases in highly volatile coals, and therefore nystagmus may be due to carbon monoxide. In support of this theory the paper attempts to establish, with considerable success, a relation between the prevalence of nystagmus and the percentage proportion of volatile matter found in coals. Taking the South Wales coal-field there is a progressive diminution in the volatile matter from east to west, and there is a corresponding decrease in the percentage of men employed below ground who were reported as suffering from nystagmus. The figures are at first sight remarkable, and as they are the main support of Dr. ROBSON'S argument, we think it worth while to give them in full.

Nystagmus in Men Employed below Ground, from 1909-1919.

		Volatile (per cent.).	Nystagmus (per cent.).
1. Monmouthshire	..	29.50	gave 4.57
2. Glamorgan East	..	21.19	" 2.22
3. Glamorgan West	..	15.50	" 1.90
4. Carmarthen	..	11.87	" 1.15

The argument is amplified at considerable length by reference to the special conditions peculiar to each district. The obvious criticism of it is that in the volatile pits the lighting is inferior owing to the

¹ See THE LANCET, 1923, i., 350.

danger of using naked lamps, whereas in the non-volatile pits the lighting is superior. Dr. ROBSON'S answer to this is contained in Part V. of his paper (read at Swansea subsequently to the discussion at Cardiff), in which he brings figures to show that, in spite of the introduction of electric lamps into the mines, which has gradually been effected since 1914, but is still far from complete, the compensation claims for nystagmus have continued to increase, but he admits that the new lamps may not have been in use long enough to indicate the results in figures.

The discussion that took place at Cardiff after the reading of the first part of the paper shows that as yet, at any rate, Dr. ROBSON'S conclusions find little support among those best able to judge. Prof. GEORGE KNOX indeed opined that the evidence that deficient lighting is the chief cause of nystagmus was not so convincing that any body of men could afford to neglect to explore every other possible avenue that might lead to definite conclusions, and Dr. LEIGHTON DAVIES leant decidedly to Dr. ROBSON'S theory. On the other hand, Dr. J. S. HALDANE, who himself discovered 25 years ago that small amounts of CO are formed at ordinary temperatures when air acts upon fresh coal, stated that the quantity is so minute that we can have complete confidence in dismissing this gas as a possible contributory cause of miners' nystagmus. As chairman of the Nystagmus Committee of the Medical Research Council, he thought it would be a misfortune to British coal-mining if, owing to the idea that nystagmus is possibly due to mine gases, effort is relaxed towards obtaining greatly superior illumination for coal-miners. Dr. T. LISTER LLEWELLYN, on whose evidence the report of the committee was very largely based, took a similar view, and so did Dr. J. J. HEALY, who suggested an explanation for the phenomenon of nystagmus based on the theory of VON KRIES that the rods and cones of the retina provide two distinct apparatus for dark and light vision respectively. Perhaps the most telling criticism of Dr. ROBSON'S figures, however, referred to the effect of the Workmen's Compensation Act on the number of nystagmus cases officially reported. As Prof. E. L. COLLIS pointed out, experience teaches that several years always elapse after a disease is scheduled before claims reach a steady annual level. Nystagmus was placed in the schedule to the Workmen's Compensation Act of 1906. The fact that nystagmus frequently arises without causing any subjective symptoms, and therefore that many men whose eyes oscillate in the dark may be unconscious for years that anything is the matter with them, must necessarily have resulted in a steady increase in the number of claims for years after the law was first passed. In 1913, soon after the annual rate had reached a point where it might naturally have remained fairly steady, the designation of the disease in the schedule was altered, and altered in such a way as to admit for compensation for the first time psychopathic manifestations of the trouble. A rise in the number of cases naturally followed. War conditions and variations in the rate of wages have since introduced disturbing factors which make any statistics of the disease based on claims very largely unreliable. Moreover, a disease with psychopathic symptoms is "catching," so that a colliery or district previously free may suddenly be "infected" with compensation claims.

Whether these psychopathic symptoms—tremors, disordered action of the heart, headaches, sleeplessness—are in reality a separate entity which might be called "miners' neurosis," to be found either

separate or combined with oscillations of the eyeball; or whether they are always secondary to the latter, and therefore parts of a syndrome of which the oscillations of the eyeball are only one part, is a matter on which there is room for differences of opinion and which ought to be further investigated. Certainly it is generally acknowledged that besides defective illumination, a factor in the disease is the constrained position of the eyes necessary for coal-hewers, a factor which Dr. A. S. PERCIVAL, of Newcastle-on-Tyne, following the late Dr. SNELL, considers to be of primary importance. The whole controversy is as yet some way from being settled. Meantime, however, we may say definitely that the arguments for the new theory are quite insufficient to afford excuse for any relaxation of the efforts which have for some years been made to provide the miners—in addition to safety lamps where necessary—with proper illumination from electric cap-lamps.

SPLANCHNIC ANÆSTHESIA.

THE administration of general anæsthetics has reached such a degree of perfection in this country that there has been but little inducement to develop local methods for abdominal operations. On the continent, where but few specialist anæsthetists exist, the bad effects of ill-administered ether or chloroform have been so pronounced that the search for a method by which general anæsthetics could be eliminated has gone on unceasingly. The latest advance in this direction has been the evolution of splanchnic anæsthesia. Whilst it has always been possible to open the abdomen under local anæsthesia painlessly, manipulation inside the cavity invariably causes distress. The visceral walls themselves are insensitive, but any interference with the mesentery or parietal peritoneum, even the withdrawal of an organ to the surface of the body, gives rise to considerable pain. The sensory nerves in question, for the whole of the abdomen above the pelvis, are derived from the celiac plexus, which they reach along the splanchnic nerves. This plexus is rather deeply situated in front of the spine and very close to the aorta and vena cava. The suggestion to infiltrate this whole area by puncture from without does not commend itself easily to the anatomist or surgeon. But by the work, amongst others, of KAPPIS, BRAUN, WENDLING, LABAT, and PAUCHET three methods have been worked out. They are puncture from behind below the last rib, puncture from below the costal margin, the needle traversing the left lobe of the liver, and puncture above the lesser curvature of the stomach after opening the abdomen. The second procedure is the most dangerous, least certain, and an unsatisfactory way. Puncture after opening the abdomen is the safest and most easy, but it is not always possible and in itself is painful. It is best reserved as an accessory method, if after puncture from behind it is found, when the abdomen has been opened, that the anæsthesia is not complete. E. KUTSCHA-LISSBERG¹ reports his experience in 178 cases, which included most operations upon the abdomen outside the pelvis. The ages of the patients ranged from 10 to 70 years. In 169 cases the anæsthesia was absolute, but in 12 of these it was combined with lumbar anæsthesia; there were two complete failures; in only three patients was resort to general anæsthesia necessary, and one of them inhaled alcohol only. Preliminary treatment consisted in the

¹ Wien. Klin. Woch., 1923, No. 12, p. 216.

administration of morphine and atropine. Scopolamine appeared to cause abdominal rigidity. In this series there was only one death in which the anæsthetic could be said to play a part. It was a man with a ruptured colon who died during the operation. He was very collapsed from the injury before the administration of the anæsthetic.

What are the dangers and complications of splanchnic anæsthesia? They are these: Reflex collapse when the needle reaches the plexus, only seen when the patient is injected sitting up; toxic symptoms which come on immediately if the needle point should be in the cavity of the vena cava or aorta, or supervene in a few minutes if the patient be unusually susceptible to novocaine; and finally, acute dilatation of the stomach and perhaps atony of the intestine a few days after operation. The collapse from novocaine poisoning can be avoided by care in technique and avoidance of too large a dose. The dilatation of the stomach is a serious complication. It arises apparently from the upset of the celiac plexus caused by the injection. The bad effects of it can be lessened by early recognition and the passage of a stomach tube. Many considerations come to the fore when the advisability of adopting the method has to be decided by English surgeons. The Teuton is a more phlegmatic individual and will submit readily to the number of needle punctures (14 or more) necessary to block both the splanchnics and the nerves of the abdominal wall. This in itself would be an ordeal for many patients in this country. The distress of being operated upon whilst conscious would be very great in some individuals. Yet it must be confessed that the comfort of the patients the day after operation under local anæsthesia is very striking. They escape the vomiting which even the most skilled general anæsthetist is unable always to prevent, and with it the exhaustion caused by the pain of uncontrolled retching, a memory always the last to fade from the mind of a laparotomised patient. Then again, it must be admitted that the toxæmia of novocaine is less than that due to a general anæsthetic. It is claimed that the mortality rate in peritonitis is less when the patients are operated upon under local anæsthesia than under ether. Probably with increasing experience it will be established that, like the spinal method, splanchnic anæsthesia has its indications as well as its limitations, and that it will come to take a recognised place in surgical technique.

THE annual oration of the Medical Society of London will be given at 11, Chandos-street, London, W. 1, next Monday, May 14th, by Dr. J. Walter Carr, who has taken as his subject Life and Problems in a Medical Utopia.

ROYAL SOCIETY OF MEDICINE.—The President, Sir William Hale-White, with the hon. secretaries, Dr. A. M. H. Gray and Mr. Girling Ball, and the secretary, Sir John Y. W. MacAlister, attended at St. James's Palace on May 4th, and formally presented the Honorary Fellowship of the Society to the Prince of Wales.

The house and library of the Royal Society of Medicine will be closed from Saturday, May 19th, to Monday, May 21st, both days inclusive.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.—At a meeting held on May 1st, Sir Robert Philip, President, being in the chair, Dr. George Henry Masson was elected to the Fellowship of the College, and Dr. James Davie Gilruth and Dr. William Arnott Dickson were admitted to the Membership of the College. The College re-elected Dr. William Russell as their representative on the General Council of Medical Education and Registration for a further period of five years. The Freeland Barbour Fellowship for Original Research was awarded to Dr. James Walker Dawson. Lord Polwarth presented to the College an autograph letter by Edward Jenner dated Sept. 14th, 1799.

Annotations.

"Ne quid nimis."

CONGENITAL MALFORMATIONS.

CONGENITAL abnormalities have always been a source of interest and speculation to mankind. In olden days they were as often as not referred to diabolical paternity, and frequently the unfortunate mother of such offspring had reason to regret her assumed familiarity with the infernal powers. Since Geoffroy St. Hilaire and v. Vrolik classified monsters on more scientific lines embryology has been invoked in explanation of them all. Yet it sometimes happens that they themselves are really the only foundation for the embryological statements made to account for them. As a matter of fact, normal embryology is an introduction to normal anatomy, and not by any means necessarily an explanation of abnormalities.

Mr. C. P. G. Wakeley gives an interesting description, in the *Journal of Anatomy* for April, of a case on which he had operated, in which were several congenital malformations of the intestinal canal; he refrains from offering any general explanation of their concurrence save what might be conceded to some failure in nutrition. In this restraint Mr. Wakeley shows a philosophic wisdom such as is not always to be found. Whether nutritional faults are to be classed among the causes or not, it is certain that no other is to be decidedly given in the present state of our knowledge. It is permissible to doubt whether abnormalities such as those he describes can be considered even as persistences of normal stages, whether, in fact, there has been any arrest at a definite developmental point, or whether the resemblance to such a stage is not merely general and superficial, the end-result of a growth that has been faulty from the beginning. In this last case there could hardly have been a "normal" stage. It is well to understand that our present knowledge of organogeny, detailed as it is, would never account for the great majority of abnormalities. Even though such a simple thing, for example, as a cleft palate may be certainly referred to failure in the growth-forces of the maxillary process, this is no explanation of it, but is merely a re-statement of the condition in other words. Such a form of re-statement is frequently given ingenuously as an explanation, but in most of the complicated forms of abnormalities even this is not possible in terms of normal embryology. The truth is that we are practically ignorant of the forces and inter-relations behind the phenomena of growth, and are only acquainted with their end-products. The accumulated forces of phylogenetic development are hidden among these, only recognisable here and there, but undoubtedly pervading the activities throughout.

This thought rises in the mind in association with the condition of anal canal in the penis, which is mentioned by Mr. Wakeley in his discussion of the cloacal malformation in his case, and is, no doubt, as he remarks, to be referred to the ectodermal cloaca. The theory that the rectum, or its lower part, is produced by a secondary downgrowth from the cloaca is not in keeping with the facts of ontogenetic development. But one would hesitate to say that it might not be a phylogenetic memory, which may find its expression under unusual circumstances. It may be that future work will show something of this sort to be at the bottom of certain monstrosities, or it may open up vistas in most unexpected directions. Not until some idea is gained of the forces at work—not of their nature but of their methods—can we really hope for much help from embryology, and in most cases we can get none at all. Yet those who, like Mr. Wakeley, carefully report and consider such cases, are doing good spadework, preparing the soil in which, let us hope, some future explanatory system will surely grow.

ECLAMPSIA AND ITS TREATMENT.

THE importance of eclampsia is strikingly shown by the figures furnished by Prof. Stroganoff,¹ who calculates that no less than 5600 mothers and 8400 children die every year in Europe from this complication of childbirth. In England the maternal mortality is as much as 25 per cent. even at the present time. It is now some 25 years since Stroganoff first published his method of treatment founded on his contention that the fits play the most important part in the high death-rate and that everything must be done if the patient is to be saved to prevent the recurrence of the convulsions. That the prophylactic method, as practised by him, is most successful is shown by his results, published so long ago as 1908, of 360 cases of eclampsia with a maternal mortality of 6.6 per cent. and a foetal mortality, not including the third stage of labour, of 21.6 per cent. If the conditions are favourable Prof. Stroganoff believes that the maternal mortality should not exceed 1 to 2 per cent. He favours the theory of the placental origin of the disease and regards eclampsia as mainly the result of two factors—the quality and quantity of the toxins circulating in the mother's blood and the increased degree of irritability of her nervous system. The increased frequency of the fits during labour he would attribute to the increase in the virulence of the toxins produced by the labour pains. Assuming that eclampsia is the result of these two factors, then the treatment should be directed towards lessening the quantity of the toxins in the blood and diminishing the irritability of the nervous system. Forced delivery, as experience has shown, does not answer the purpose. As he believes the occurrence of the fits to lead to a great increase in the amount of toxins in the blood, then it is essential to try and stop them. The fundamental principle underlying this prophylactic method, then, is to prevent the reappearance of the fits, and Prof. Stroganoff endeavours to accomplish this by the combined administration of morphia, chloral hydrate, and chloroform. The effect of these drugs is to calm the patient, produce sleep, to lessen the spasm of the blood-vessels, and to lower the blood pressure. To diminish the concentration of the toxins in the blood, venesection and the introduction of fluid into the body are also practised. In carrying out the treatment, the first principle is to remove all sources of irritation. The second principle, the administration of narcotics, is disputed by many authorities, but there is a large amount of evidence accumulating from day to day in its favour. According to the author the unfavourable effects which have been found to follow the administration of morphia are largely due to overdosage. He never administers more than 2/3 gr. in the 24 hours. The best drug is chloral hydrate up to doses of 100–140 grains in the day. The combination of small doses of chloroform with the chloral hydrate appears to be beneficial, and given in this way does not seem to give rise to the harmful effects which follow the prolonged administration of chloroform. Minor operative procedures to hasten delivery may be undertaken, but with increasing experience they have become less and less necessary because the prophylactic method by itself gives such good results that labour may be allowed to occur spontaneously. Venesection to a moderate degree seems to be undoubtedly beneficial.

The results obtained by Prof. Stroganoff are immeasurably superior to those which follow most other methods of treatment; the only series of results which bear comparison with his are those in use at the Rotunda Hospital, ably set out by Dr. Gibbon FitzGibbon in a recent article in our columns.² The publication of these papers at the present time serves as a timely reminder that forced delivery, whether practised by the abdomen or by the vagina, gives extremely bad results, and we hope that a careful study of these figures will go far to convince the advocates of the treatment of eclampsia by

Cæsarean section that this procedure has nothing to recommend it and should not be performed. Eclampsia is not a common disease and undoubtedly as a result of greater antenatal care of the mother will become rarer and rarer, but it is to be hoped that this method will receive a careful and exhaustive trial in this country and that those who employ it will make themselves conversant with the precise details as laid down by Prof. Stroganoff. The treatment of these cases has in the past often been so complicated and included so many different factors that any comparison between different methods has been almost impossible. We hope, therefore, that the warning conveyed in the report of the Committee appointed by the Section of Obstetrics of the Royal Society of Medicine to consider the question, "that the majority of the fatal cases were overtreated and that in a considerable number of cases excessive treatment must have been a contributory factor in bringing about the fatal result," will be taken to heart.

RENAL TUBERCULOSIS.

At a meeting of the Academy of Medicine on Feb. 9th, Prof. L. Ferria gave some interesting details based on his experience of 126 cases of renal tuberculosis under his care at the urological section of the Hospital of S. Giovanni at Turin.¹ These reached the high proportion of 47 per cent. of all cases of renal suppuration (269), the disease being unilateral in 106, of which 89 were submitted to operation. He called attention to the rarity of partial occlusion of the kidney and the less rare condition of total occlusion to which he attributed the majority, if not all, of the few cases of clinical cure of renal tuberculosis. The bladder was implicated early in 80 per cent. of the cases, and in the great majority of them the course of the disease was a descending one. In contrast to the vesical symptoms, those attributable to the kidney were little if at all in evidence; pseudo-colic was rare, and painful sensations might be felt on the healthy side due to reno-renal reflex. Palpation positive in many cases might be negative and deceptive, as when ptosis of the liver gave an apparent increase in volume to the right kidney. On the other hand, a thickened and indurated ureter felt per rectum or per vaginam had a definite diagnostic value. The possibility of surgical cure rested on the knowledge that the affection was unilateral, and on the integrity or at least the functional efficiency of the kidney left in situ. The best means of ascertaining these fundamental conditions were furnished by cystoscopy and ureteral catheterisation. But when the latter was not possible, Ambard's coefficient, when properly interpreted, afforded useful help; in 11 cases in which it was below 0.100 the author proceeded with complete success to nephrectomy without resort to ureteral catheterisation, because either palpation or the indigo-carmin test, or double exploratory lumbotomy (if a convenient hybrid word may be pardoned) gave him assurance that one of the kidneys was so profoundly disorganised that the coefficient was favourable to a state of functional efficiency in the other. Out of 89 nephrectomies the author had six deaths due to the operation and six in the first six months after. The subsequent history of these cases revealed the fact that death from tuberculosis of the remaining kidney was very rare, occurring in only two instances; more frequent was death from chronic pulmonary tuberculosis, cachexia, and meningitis, which occurred in seven cases. These were operated on in a condition of advanced vesical tuberculosis, and this confirms the necessity of not waiting too long before adopting surgical measures. The practising physician, whenever he encounters patients who have suffered for some time from cystitis of an irregular and variable course rebellious to ordinary treatment, especially if a history of previous gonorrhœa is wanting, and if calculus and

¹ My Improved Method of the Prophylactic Treatment of Eclampsia, Brit. Jour. Obstet. and Gynec., vol. xxx., No. 1, 1923

² THE LANCET, March 31st, 1923.

¹ La Riforma Medica, March 19th, 1923.

prostatic hypertrophy can be excluded, should think of tuberculosis. Once a diagnosis of urinary tuberculosis is made it may be definitely affirmed that there is renal tuberculosis except in cases of prostatic tubercle in men, a condition easily recognisable, and in the very rare cases of tubercle of the uterine appendages in women spreading to the bladder. As soon as the diagnosis of renal tuberculosis is established nephrectomy is clearly indicated if the state of the other kidney allows; only when nephrectomy is performed early is it a fairly safe operation.

THE CEREBRO-SPINAL FLUID IN MENINGITIS.

EVER since lumbar puncture came into general use, persistent efforts have been made to determine the existence, and the degree of virulence, of meningitis of aural origin by means of chemical and microscopical examination of the cerebro-spinal fluid. If this could be done with exactitude it would be of inestimable value both for prognosis and as an indication for operation. That exactitude has not yet been attained is shown by the numerous criteria which have been adopted, and by the different value placed on each by different observers. Increased pressure, turbidity, increase of globulin, diminution of sugar-reducing power, the number of cells, whether polynuclear or mononuclear and whether showing signs of degeneration, and finally the presence or absence of bacteria, and their varieties, have all been used as criteria in estimating the presence and virulence of meningitis. Dr. Holger Mygind, of Copenhagen,¹ considers the cell count of the greatest importance; he believes that meningitis is probable if three or more cells are present per cubic millimetre, although the fluid does not become opalescent until more than 200 cells per cubic millimetre are present. But as a guide to prognosis, no one point, nor even the sum of all, is infallible; many cases with turbid cerebro-spinal fluid recover, and a considerable number have recovered after micro-organisms have been found in the fluid, as in the case recently reported in THE LANCET by Mr. H. L. Martyn.² In an article on the Clinic and the Laboratory in the Classification, Prognosis, and Treatment of Otitic Meningitis, Dr. Henri Aboulker, of Algiers,³ emphasises the fallacy of trusting too greatly to laboratory methods of diagnosis, and considers the clinical examination to be of greater importance. He finds no definite relationship, in a large series of observations, between the various criteria; for instance, bacteria with intact lymphocytes, and damaged lymphocytes in an aseptic fluid. Nor is there a constant relation between the character of the fluid and the outcome of the case, a benign purulent type being fairly well recognised and, as already mentioned, a small number of cases with bacteria recovering; Aboulker reports three such cases and Mygind four. Dr. S. G. Askey reports another in our present issue. Aboulker is in agreement with the remarks we made in a recent annotation⁴ anent the term "meningism," when he says "il n'y a pas de fausses méningites, il n'y a que des erreurs de diagnostic." Mr. Edward D. Davis, who, as we understand from the recent correspondence in our pages, follows Mygind in placing considerable reliance on the cell count as an indication for operation, has just communicated to the Royal Society of Medicine (see p. 955) his views on the morbid anatomy and drainage of otitic meningitis. He has made a series of experiments with the injection of methylene-blue to demonstrate the paths of infection from the internal ear and from the region of the lateral sinus; and he comes to the conclusion, among others, that lumbar puncture is inefficient as a method of drainage, but that repeated lumbar puncture does not tend to increase the area of suppuration. The cerebro-spinal fluid obtained by lumbar puncture does not necessarily give an accurate picture of the state of the meninges,

because the thick gelatinous pus, which forms in the subarachnoid space, may shut off the extension of the inflammatory products and prevent them from reaching the spinal canal; thus the outlying regions of the cerebro-spinal system may show only the signs of a serous meningitis, while a localised suppurative condition is present in the cranial cavity.

In fine, the signs elicited by lumbar puncture are not infallible, but are nevertheless of great value for diagnosis and prognosis; laboratory tests must here, as elsewhere, be correlated with the signs disclosed by clinical examination. When so used they form a fairly reliable guide to the state of the meninges and to the advisability or inadvisability of operation. It is on early diagnosis and, where necessary, prompt operation that the possibility of reducing the mortality depends.

NEW DISINFECTION LAWS IN GERMANY.

UNDER a decree recently issued by the Prussian Minister of Health an entirely new system of disinfection in infectious diseases is formulated. The essence of the decree is, first, to organise disinfection at the bedside of the patient during the whole course of his illness in such a way as to make a final disinfection of secondary importance, or, indeed, altogether superfluous; and, secondly, to dispense with formalin vapour and dry heat in the disinfection of rooms and articles by substituting the free use of a disinfectant fluid throughout the course of the illness. This ministerial decree has reference only to the contagious diseases specified in the Act of August 28th, 1905, including tuberculosis, diphtheria, acute meningitis, scarlet fever, typhoid fever, dysentery, and trachoma, while the Act of 1900 relating to plague, cholera, typhus, and small-pox, remains in force with all its provisions. The principle underlying the new regulations is that in the vast majority of cases infection occurs from individual to individual either by direct contact or by the transmission of germs over a short distance. Thus it is only the patient or the carrier who needs to be supervised, the part played by fomites in the transmission of infection being negligible, except where contamination is recent and massive, any bacteria deposited quickly losing their virulence and their vitality. Infection occurs almost entirely in one or more of three ways: by the projection of droplets of saliva—or more accurately of droplets of nasal, pharyngeal, tracheal, or bronchial secretion—as in tuberculosis, diphtheria, cerebro-spinal fever and scarlet fever; by faecal material or urine, as in typhoid fever and dysentery; and by the hands, as in these and other diseases, such as trachoma. Any method of disinfection must therefore take account of these three possible sources of contamination.

The regulations in the case of diphtheria, which we may take as an example, include, on the one hand, a detailed list of articles to be disinfected: utensils, body linen, sputum, floor; and, on the other hand, instructions to the patient to turn away his head and to cover his mouth when coughing, and to the attendants to avoid all unnecessary contact, to place themselves behind him when handing him anything and to stand at a distance of two arm-lengths from him when he coughs. The disinfectant to be used is a 1 in 1000 solution of corrosive sublimate—a choice apparently made upon grounds of economy—failing which cresol may be used. At the end of the illness, providing that the instructions have been faithfully carried out, nothing remains to be done, although in exceptional circumstances, such as in overcrowded tenements or in lodging-houses, the medical officer of health may prescribe formalin or steam disinfection as an additional precautionary measure. The municipal authority is charged with the duty of distributing the disinfectants to the public, a charge being made, except in the case of necessitous persons. The heaviest responsibility in connexion with the scheme falls upon the municipal nurses and the official disinfectors who have to attend a preliminary course of instruction lasting, in the case of the nurses, at least eight days, exclusive of Sundays, and in the

⁴ THE LANCET, April 28th, 1923, p. 862.

case of the "disinfectors" a clear fortnight. As soon as the police have been notified of a case of infectious disease a nurse visits the family, repeating the visit every two or three days until the end of the illness in order both to instruct the members of the household in the prescribed ritual, and also to see that the directions are properly carried out. The rôle of both nurses and disinfectors—the latter intervening as a rule only where no nurse is available—being strictly confined to prophylactic measures, no interference of any kind with the treatment of the patient is allowed on the part of these officials under penalty of forfeiture of their diploma or licence, and even their presence in the sick room is contingent upon the permission of the doctor in attendance and the invitation of the relatives of the patient.

The scheme has been criticised in Germany both on hygienic and on economic grounds. Not only does some doubt appear to be felt as to how far it will be found practicable adequately to supervise and control this bedside disinfection, but it is recognised that an extremely large personnel will be required. Moreover, as the disinfecting stations will still have to be kept up for the diseases specified under the Act of 1900, a double expenditure will inevitably be entailed. On the other hand, it is certain that the scheme will result in a new and widespread campaign in the instruction of the public as to the aetiology and prophylaxis of the commoner infectious diseases, and such an educational propaganda can hardly fail in the long run to react favourably upon the public health of the country.

ELECTRO-COAGULATION IN LUPUS.

THE Finsen Institute in Copenhagen is to be congratulated on the pioneer spirit in which its staff keeps alive the best Finsen traditions of scientific research. Thanks largely to the observations of A. Reyn, chief of the Institute, lupus has come to be regarded as being, in many cases, connected with a deep-seated focus of tuberculosis. Hence the growing tendency at the Finsen Institute to give general as well as local treatment in lupus. Local treatment is, however, of great importance, and a recent paper by Dr. A. Vibede,¹ of the Oto-Laryngological Department, gives a very hopeful review of the experience of the past two years in the treatment of lupus by electro-coagulation, the apparatus used being a powerful diathermic plant supplied by Löwenstein, of Berlin. After giving an account of the technique, Dr. Vibede analyses the results obtained in 283 cases in the period November, 1919, to August, 1921. Several of these 283 patients had other tuberculous lesions, and as many as 221 had undergone some other local treatment, but without great success. It will thus be seen that the disease in many cases was of an obstinate character. As many as 90 discontinued treatment or could not subsequently be traced. Of the remaining 193, no less than 160 were apparently cured, and 27 were improved. Considering that the duration of treatment was less than a month in 128 cases, the results must be considered as remarkably good, and they compare well with the results obtained by Reyn's electrolysis—the only method which, in Dr. Vibede's opinion, can be expected to compete with electro-coagulation. The results of electrolysis have been shown by Strandberg, of the Finsen Institute, to be comparatively poor; of 200 patients thus treated, only 96 were apparently cured. Thus electrolysis cures approximately only 50 per cent., while electro-coagulation cures 82 per cent., and in much shorter time. It also does not entail the giving of the large doses of iodine required for electrolysis. Further advantages of this method are its not drawing blood, the ease with which it can be carried out by a skilled specialist, and the smallness of the risk of spreading infection. On the other hand, it has certain very definite disadvantages. The cost of the apparatus is considerable, not a little dexterity and practice are required of the operator, and, last but

not least, the pain of the treatment cannot be overcome by local anaesthesia. Even when the treatment is carried out skilfully it is very painful, and the pain of electrical and thermal stimulation may radiate far beyond the field of operation. Yet most of the patients at the Finsen Institute were able to endure the treatment without a general anaesthetic when the application was of short duration, but it was sometimes necessary to induce shallow ether or ethyl chloride anaesthesia.

THE CLASSIFICATION OF STREPTOCOCCI.

AN adequate classification of the streptococci has not yet been achieved, and those pathologists who have had the experience of examining sputa and throat swabs from cases of naso-pharyngeal catarrh—especially in connexion with recent epidemics of influenza—know only too well what a perplexing pursuit this examination can be. As clinical pathology extends its bounds this large and heterogeneous class of organisms continues to grow and confusion seems to increase rather than diminish. It was thought at one time that the fermentation of sugars would solve the difficulties, but disappointment has followed. Sugars supplied are not always pure, and the autoclaving process of sterilisation leads to chemical changes which have doubtless, in the past, been responsible for discrepant results. A new fermentation tube by means of which carbohydrates may be separated from proteins during sterilisation has recently been devised by Dukes,¹ which may now obviate this difficulty. Again, the old difficulty of obtaining pure cultures—which is of paramount importance in classification work—is a very real one in the case of an organism such as the streptococcus, witness the confusion which reigns in the description of the morphological characteristics of the organism in the various standard text-books of bacteriology. The truth is that the growth of bacterial subcultures on pure lines is by no means an easy task.

There are indications, however, that advances in classification are being made. The use of the bile-solubility test for separating off the pneumococcus group, for instance, has been a considerable advance, and it would be a step forward if clinical pathologists in reporting on the organisms of the pneumococcal and streptococcal groups, would make it a rule to state whether or not the strain reported on was bile-soluble. At the present moment it almost seems as though we might regard bile solubility as the crucial test of the true pathogenic pneumococcus, but whether we should be justified in going a stage further and regarding organisms morphologically and culturally resembling pneumococci, but not bile-soluble, as streptococci is another question. Probably, also, the separation of the heterogeneous Group IV. Pneumococci, when it is achieved, will produce some surprises. For the true streptococci the hæmolysis of blood-agar media seems to offer the best means of classification. Brown² separates these organisms into alpha and beta types according to the degree of hæmolysis, and ascribes the title gamma type to non-hæmolytic varieties. Valentine and Mishulow³ have investigated a number of strains by this method, and confirm Brown's results. More recently still Miss Mary L. Cowan⁴ has separated these hæmolytic strains into "rough" and "smooth" types, and has shown "an almost complete lack of virulence on the part of the 'rough' elements," which may throw light on the discrepancies noted by different workers, with the hæmolytic streptococci.

On the clinical side these hæmolytic streptococci are equally variable; some are found in fulminating broncho-pneumonias and empyemas, others in the crypts of chronically hypertrophied tonsils, and it seems difficult to believe that these strains are all one and the same species of organism. Virulence tests in the

mouse, and immunity tests such as agglutination, precipitation, and complement fixation may help to differentiate further these apparently anomalous characteristics. Until some adequate classification is forthcoming, it is obvious that prognosis in regard to streptococcal infections must be guarded, and our opinions on the use of anti-streptococcal serum and streptococcus vaccine in treatment must be characterised by extreme caution.

OLEO-BISMUTH IN SYPHILIS.

THE recent introduction of bismuth as a specific remedy for syphilis has been followed by an extensive trial of numerous preparations. The original French preparation, trépol, has been supplanted by a new trépol, the intramuscular injection of which is said to be comparatively painless. At present there is a tendency in favour of the insoluble preparations of bismuth in preference to the soluble preparations, and it is held in certain quarters that the specific action of these preparations depends mainly, or wholly, on their content of metallic bismuth. The molecular arrangement of the various bismuth preparations seems to be a matter of comparatively slight importance, and in this respect, at any rate, the bismuth preparations differ from the salvarsan group. In the *Schweizerische medizinische Wochenschrift* for March 22nd there is a paper by Dr. E. Ramel of the Dermatological Clinic in Zurich. The preparation which he recommends is oleinate of bismuth (l'oleo-bismuth "Roche"), the formula of which is $(C_{17}H_{33}COO)_3Bi$. The bismuth is very finely suspended and the stability of the suspension is so great that even after standing for months the solution shows no deposit. The treatment consists of bi-weekly intramuscular injections of 2 c.cm., 20 or 30 injections being given in one series during which the total amount of bismuth administered is 2-3 g. The therapeutic results achieved in Zurich have been quite equal to those obtained with the painless preparation of trépol, and only in one or two cases were the injections followed by the appearance of a slight bismuth line in the gums. This line soon vanished after the drug had been discontinued, and in no case did the injections give rise to albuminuria. Bismuth, it would seem, has a more rapid effect on the cutaneous manifestations of syphilis than on the Wassermann reaction, which may persist long after the secondary eruptions have vanished. But, as Dr. Ramel suggests, the ultimate effect of bismuth on the Wassermann reaction may prove lasting, in spite of the delay in converting a positive to a negative reaction. Salvarsan and bismuth, being markedly different in their serological actions, may prove mutually supplementary, and Dr. Ramel, like other advocates of bismuth, does not regard it as a substitute for, but rather as an adjuvant to, the salvarsan group.

ALCOHOL AND PNEUMONIA.

To determine the influence of the consumption of alcohol upon the prognosis of the disease, Dr. Joseph A. Capps and Dr. George H. Coleman¹ recently made a study of 3422 cases of lobar pneumonia which were admitted to the Cook County Hospital, Chicago, during the course of eight years, which include the period 1911-17 before prohibition, and the two years after prohibition, 1921-22. The intermediate years were omitted on account of the streptococcus and influenza epidemics, which produced atypical forms of pneumonia. It was found that the mortality was considerably higher in moderate drinkers—i.e., those who drank regularly two or more glasses of beer or one or two glasses of spirits daily—than in abstainers or in those who drank less than two glasses of beer a day, or who drank spirits occasionally, while in excessive drinkers the mortality was highest of all. The average age of the moderate drinkers in the series was about five years higher than

that of the abstainers or light drinkers, and the average age of the excessive drinkers was about three years higher than that of the moderate—a curious fact which the authors regard as "likely" but do not stop to explain. But the mortality was reckoned separately in each group by decades in order to exclude the age factor entirely from the problem, with the result that the death-rate among moderate drinkers showed a remarkable increase over the abstainers, and the death-rate among excessive a still greater increase over the moderate. Although the writers do not claim that prohibition is lessening the death-rate from pneumonia, they have observed within recent years an increased proportion of abstainers or light drinkers and a corresponding decrease in heavy drinkers. The practical disappearance of delirium tremens within recent years, as compared with its frequency before prohibition, is also evidence of the lowered rate of alcohol consumption. The present paper recalls an article which was published two years previously by Dr. J. L. Miller,² whose observations were also made at the Cook County Hospital, on the effect of prohibition on the incidence of fatal cirrhosis. Dr. Miller, who carefully investigated the history of every case of cirrhosis admitted to his wards, never failed to obtain a history of marked alcoholism. In 1920, the year following the introduction of prohibition, there were only 19 cases of fatal cirrhosis admitted, all but one of which gave a history of chronic alcoholism, as compared with 48 cases of cirrhosis admitted in 1919, 87 in 1918, and from 137 to 160 in each of the years 1910 to 1917. Dr. Miller concluded that fatal cirrhosis, in the United States at least, was associated largely, and possibly entirely, with the use of alcohol.

HERPES ZOSTER GENERALISATUS.

In a review of the literature, with the report of a personal case, Dr. Mihran B. Parounagian and Dr. Herman Goodman,³ of New York, remark that the first case of generalised herpes zoster was reported by Haslund, in 1897, in a man, aged 59, who presented a left dorso-abdominal zona, with additional vesicles on the trunk and extremities, left border of the tongue, and mucous membrane of the gums. The temperature was 102° F. The disease lasted about three weeks and ended in complete recovery. The writers have collected about 25 other cases, most of which occurred in elderly persons who were not very robust. Although age alone is no objection to the existence of varicella, the generalised eruptions associated with herpes zoster in advanced adult life have always been described as different from varicella as ordinarily seen. Until, however, the bacteriological aetiology of herpes zoster is established, the question of the identity or non-identity of herpes with varicella cannot be satisfactorily answered. In most cases, including that reported by the writers, the aberrant vesicles were scanty in comparison with the primary segmental eruption. In two cases, however, reported by Colombini and De Amicis respectively, the secondary eruption was remarkably extensive, occupying the cervical, cervico-brachial, dorso-pectoral, dorso-abdominal, lumbo-inguinal, sacro-sciatic, and lumbo-femoral regions on both sides. The present writers' case was that of a man who gave his age as 64, though he appeared to be many years older. In addition to a well-marked eruption of right abdominal herpes zoster of about a week's duration he presented numerous scattered vesicles and small, ill-defined papules on the trunk, especially anteriorly, on both flanks, axillæ, thighs, shoulders, and arms. The lower part of the legs and forearms contained hardly any lesions, and the face and buccal mucosa were free. A diagnosis of abdominal herpes zoster, accompanied by varicella, was first made, but that of generalised herpes zoster was substituted afterwards.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

XIX.

HEART FAILURE: THERAPEUTICS.*

It is remarkable what a large proportion of patients with heart disease fail in the same way. For example, one who has been breathless on exertion for many years with mitral stenosis acquires a rapid irregular pulse which is due to the onset of auricular fibrillation. He then becomes more breathless, the liver swells from venous congestion, and the legs become oedematous. We will take this common example of heart failure and consider the general management, the diet, the use of digitalis and other remedies, and the treatment of certain special conditions.

General Management.

In health the rate of the heart is lowest in recumbency, therefore in failure this position must be regarded as beneficial. Where both the abdomen and the thighs are greatly swollen, however, the pressure on the diaphragm may only be relieved by sitting out of bed. If, therefore, bed has become intolerable, but not unless, one should accept the fact with good grace and make suitable dispositions. A sufficiency of blankets should encircle the lower half of the body. A "heart chair" may be improvised by placing the edge of a firm heavy table in front of an easy chair with not too sloping a back or well filled with pillows behind. Patients like to lean forward upon such a support and may be able to sleep with the head resting on the arms folded on the table. The room must be warm though well ventilated, and some patients derive great satisfaction from a draught of air if it is not too cold.

Diet.

A diet of milk alone, not more than $1\frac{1}{2}$ –2 pints in the 24 hours, is best suited to the stage of severe failure. It may be given hot or cold, flavoured with tea or coffee, at four-hourly intervals. On no account should more be pressed upon the patient; for food will not save him, whereas a quiet stomach free from flatulence and tolerant of medicine will help to do so. This restricted milk diet also provides the advantages of a small fluid intake and a minimum of salt. In a few days or a week solids may be given in addition, and cups of tea and coffee allowed, but still the total daily liquid should remain below two pints. If the patient has never been able to take milk or it proves unsuitable, a dry diet may be composed of toast with a little butter, eggs, custard and baked apple, minced or potted meat sandwiches, fish, and chicken. These should be arranged in definite small meals amply spaced. A small cup of tea or coffee is permissible, or half a tumbler of water, but again the daily liquid should be limited.

Medicinal and Other Treatment.

Suitable aperients are calomel gr. i.–ii. overnight, followed early next morning one hour before any food or drink is taken by sulphate of soda, drachms i.–iv., in hot strong solution as required. Drastic purges and diaphoretics of any kind are not indicated in cardiac dropsy.

1. *If failure is extreme and life seems in danger*, we rely upon three measures—venesection, oxygen, digitalis.

The indications for *venesection* are orthopnoea with cyanosis and distended veins. If these are present it matters little what the lesion is. If very urgent, blood may be let from the external jugular vein without hesitation. As in the arm nothing is required but to insert the point of a bistoury or abscess knife, and to

cut outwards through the vein; it is unnecessary to make a big operation of it. There is sometimes difficulty in removing enough blood; for not less than 20–30 oz. should be taken, as the object is to reduce the mass of blood in circulation and thereby to relieve the exhausted pump. The immediate relief is pronounced and will justify the procedure to the patient and his friends, though it cannot be expected that the relief from this means alone will continue.

Oxygen is properly used whenever there is much cyanosis with dyspnoea. It cannot be given in too great a concentration, so the tube should be as close to the mouth as possible. A far better method is to connect the tube with a soft rubber catheter. When the right gentle flow is obtained it is oiled and pushed straight back through the nostril for about three inches and left there. It is fixed by a slip of strapping to the cheek, and the connecting tube is loosely moored to the pillow beyond the shoulder by a large safety-pin. Oxygen can thus be given continuously or for definite periods according to need.

Digitalis, as commonly given, has only one disadvantage—it takes about two days to come into action. If it seems too dangerous to wait for so long, a digitalis effect may be obtained within an hour by an intravenous injection of *strophanthin*, gr. 1/200 (obtainable in ampoules). This is neither the maximum nor a dangerous dose, and it may be repeated in 12 hours if required. But this injection is not to be used at all if digitalis has already been given, otherwise the total amount of digitalis bodies in the system may be reinforced to a dangerous level. Therefore, if digitalis has already been given, or if oral administration is preferred, a dose of 15–20 minims of the tincture four-hourly is the least dose likely to act in time to affect the outcome. It is for just such urgent cases of failure, as an alternative to intravenous strophanthin, that the massive doses of digitalis suggested by Eggleston are likely to come into use. In the modified course, $1\frac{1}{2}$ drachms of the tincture forms the first dose; 1 drachm six hours later the second; and $\frac{1}{2}$ drachm six hours later still the third and last, completing the total required by the heart for the time.¹

When much fluid is present in the chest—and a right hydrothorax is not uncommon—removal of the fluid may quickly reduce an urgent dyspnoea. The same is true to a lesser extent of extreme ascites. Now and then, patients are seen with apparently hopeless failure and gross oedema involving the whole body including the thorax and even the arms. Venesection may be difficult and there may be no time for medicinal measures. In such a case the best treatment is to give oxygen and to incise the legs as described later.

2. *In Failure of Average Degree.*—When life does not seem in danger but the symptoms and signs of failure are severe, a course of rest and digitalis may be all that is required for recovery. As soon as the patient is seen tincture of digitalis should be ordered in a dose of 1 drachm daily, not less; for example tinct. digitalis, B.P., ℥ x., aq. chloroformi ad oz. $\frac{1}{2}$, four-hourly. There is no advantage in combining any other drugs with it, least of all iodide or nitrite, for digitalis does not in therapeutic doses raise the blood pressure, and the simple solution of digitalis scarcely irritates the stomach at all. Within two or three days its beneficial effect should begin to be seen. The patient will be less breathless, the urine will increase in amount, and the pulse-rate will be reduced. But the dose should not be reduced until improvement is more pronounced. If nausea is provoked and the pulse-rate has fallen to 60–80 a minute, the dose should be reduced to 10 minims three times a day. Sometimes it is not possible to obtain the full effect on the heart before a vomit occurs; in such a case the drug should be stopped to be continued afterwards in the half dose (30 minims daily). There is no danger in giving digitalis in adequate doses if heed is taken of the toxic signs—(a) nausea and

* An article in this series, entitled Heart Failure: Preventive Treatment, appeared in last week's issue of THE LANCET.

¹ THE LANCET, 1922, II., 703.

vomiting, (b) a pulse-rate below 60, and (c) digitalis coupling (bigeminy due to an extrasystole after each normal beat). When any one of these is found digitalis should be stopped.

Special Conditions.

1. *Insomnia*.—The measures used in urgent cases, as outlined above, are the surest ways of procuring sleep. In some patients a single dose of whisky, 1-2 oz., will act as a soporific. If something more is needed paraldehyde may be given in a dose of 1-2 drachms, preferably as capsules each containing 30 minims. If there is pain or excessive discomfort, an injection of morphine gr. $\frac{1}{4}$ is indicated.

2. *Vomiting*.—Heart failure itself may be the cause of vomiting, especially if the bowels are confined and the diet has not been modified. It may even be necessary to repeat the dose of digitalis which has been vomited or to substitute a digitalis pill. If there is vomiting within a day or two of taking digitalis, and other signs of digitalism are absent, it is most unlikely to be due to the drug. I am suggesting that patients often object to digitalis on a trifling pretext, such as a single attack of vomiting, or alleged headache, or diarrhoea, when these are not due to digitalis and when digitalis is urgently required by the patient's condition.

3. *Obstinate Dropsy*.—If digitalis alone does not remove the dropsy, the combination with mercury, as in Guy's pill (e.g., fol. digit., hyd. c. creta, pulv. scillae, aa gr. i), t.d.s., may produce diuresis. If not, the most valuable diuretic is theobromine sodium salicylate, B.P. It is given in doses of 10-20 gr. t.d.s., either in tablets or in a mixture well flavoured with syrup of ginger. It may be used at the same time as a moderate daily dose of digitalis, or instead of digitalis for a few days only. If drugs along with rest do not dissipate all the oedema a salt-free diet may assist. This is composed of salt-free bread, biscuits or scones, with eggs, custard, milk, and fresh butter. No salt is to be added at table or in the kitchen.

When all these measures have failed, there remains the mechanical removal of the dropsical fluid by tapping the abdomen and by puncture of the legs. For the latter, the patient should sit in a chair for 12-24 hours so that the water can gravitate to the pendent limbs. The feet are then placed in a large tin, and after careful washing they are painted with a weak solution of iodine. With a fine tenotomy knife or a large flat surgical needle, tiny incisions, 10-20 in number, are made along the front of the leg and dorsum of the foot, allowing sufficient area of untouched skin between them. As with venesection, these patients are in such a plight that they rarely object to the procedure. The blankets should be wrapped widely round the basin so that nothing touches the skin, and the fluid is allowed to stream down. In a day or two when the copious flow has ceased gauze should be applied and the patient should return to bed. Occasionally the circulatory improvement from the removal of fluid exceeds the bounds of reasonable expectation.

A VOLUNTARY HOSPITALS COMMITTEE REPORT.

THE Voluntary Hospitals Committee of 1921, of which Viscount Cave was chairman, made, among other recommendations, one, that a Voluntary Hospitals Commission should be formed which would have as its principal duty the administration of the grant made by Parliament for the temporary relief of hospitals, which had fallen into financial difficulties, and that this Commission should be assisted by a number of county or county borough committees to act as its local advisers. The Voluntary Hospitals Commission, of which Lord Onslow is chairman, was constituted in accordance with the first of these recommendations, and it at once gave effect to the second by arranging for the formation of county and county borough committees throughout the country.

The first report of such a county or borough committee to reach us is that of the Surrey and Croydon Voluntary Hospital Committee, which is composed of representatives of the county council and borough council, including Dr. J. Cates, county medical officer of health, hospital representatives, local medical practitioners, and nominees of the Voluntary Hospitals Commission. These include Lord Cave, who was elected chairman of the Committee, and Sir Alfred Bingley was appointed its honorary secretary.

Report on the Hospital Accommodation Available in the Surrey Area.

At the request of the Committee, Dr. Cates prepared a report showing the extent and distribution of the accommodation available in the voluntary hospitals of the area, with suggestions as to the alterations and additions considered desirable. Dr. Cates's memorandum, reproduced as an appendix to the report, gives a complete survey of the resources and requirements of the Surrey area, so far as they relate to voluntary hospitals. In estimating the requirements of the county of Surrey he has found difficulties which would be equally inseparable from an attempt to estimate the adequacy of the existing accommodation in any county, and are thus of general interest. He points out that it is unsafe to gauge the adequacy of the accommodation at a hospital by the length of the list of patients awaiting admission, because the knowledge that there is a difficulty in obtaining beds soon acts as a deterrent both to medical men and their patients, and the authorities of a hospital may think that the needs of the locality are satisfied because there is no rush for vacant beds. Again, the absence of applicants may be due to the dislike of the rules of the hospital, dissatisfaction with the charges imposed, aversion to a member of the staff, or some other cause for the unpopularity of the institution. On the other hand, a hospital may have a long list of patients seeking treatment and rarely have a vacant bed because it is popular and attracts patients from a wide area. Medical men vary in the use they make of institutional treatment; in one district nearly all persons needing nursing are sent into hospitals, while in another admission is only sought for patients requiring an operation.

It seems clear, therefore, that some other basis for inquiry must be taken if a true estimate of the adequacy of hospital accommodation is to be made.

A Survey of Local Hospitals.

In order to form conclusions as to the adequacy of hospital accommodation Dr. Cates instituted inquiries as to 25 hospitals in the county and grouped the results in a table, included in the report, under the following headings:—

Name of hospital; medical staff; visiting surgical staff; other specialists; resident medical staff; nursing staff (trained and untrained); beds (men, women, cots, and private); number of patients in hospital per year; baths

(men, women, staff); sanitary accommodation (men, women, staff); operating theatre; out-patient department; mortuary; special department; method of admission; proposed extensions; maternity cases (normal or for surgical operations); remarks and recommendations.

Much interesting information is here collected and at the risk of appearing to emphasise the deficiencies rather than the best features at some of the hospitals we quote certain of the recommendations in the last column, for these are of more than local interest.

Extensions, in accordance with suggestions made by the Hospital Committee, are recommended at the Frimley Cottage Hospital, the Royal Surrey (Guildford) County Hospital, the Weybridge Cottage Hospital, and the Victoria Hospital, Woking. Dr. Cates notes that more beds are required at the Carshalton District Hospital, the Sutton Hospital, the Surbiton Hospital, the Epsom Cottage Hospital, and Royal Surrey (Guildford) County Hospital; more beds for children at the Dorking and District Hospital, for women and children at the Victoria Hospital, Leatherhead, and for women at the Victoria Hospital, Kingston. Mortuaries should be provided at the Cobham Cottage Hospital and Horley Cottage Hospital. Other interesting comments are made: for example, at the Caterham Cottage Hospital X ray treatment of ringworm is carried out by the matron, and a note is made by Dr. Cates that ringworm should be treated by a medical man. More domestic accommodation, bath-room and lavatory accommodation is desirable at the Sutton Hospital. As to the Reigate and Redhill Hospital he is of opinion that a new hospital is required, since money spent on an extension would be largely wasted; the needs of the district call for a modern hospital of at least 100 beds. As to the Molesey, East and West, Hospital, Dr. Cates considers that the premises should not be used as a hospital. It is noticeable that of all the hospitals under review two only, the Royal Surrey County Hospital and the Sutton Hospital, have a pathologist attached to the staff; 13 of the hospitals have a dentist attached. One only, the Thames Ditton Cottage Hospital, appears to have a gynaecologist, one, Surbiton Hospital, an aural specialist, three an ophthalmologist. To seven only of the hospitals is an X ray department attached.

Criterion for Admission to Hospital.

From a public health point of view a person should be admitted to hospital if complete recovery is jeopardised or convalescence is likely to be retarded by treatment at home. At the majority of institutions visited, it was stated that the beds were inadequate for the needs of the area. In assessing the value of this statement, it should be remembered that at many of the hospitals surgical emergencies—accidents, hæmorrhage, and the rupture of vessels—form the bulk of the work to the exclusion of more common and equally serious conditions such as pneumonia, rheumatic fever, and diseases of the heart. Until recently, it was the custom for medical men to rely on obtaining admission for any outstanding case into a London hospital. The authorities of these institutions are now reluctant to accept persons from the home counties unless they reside in the metropolitan area, and the cost of travelling still further discourages patients from seeking treatment there.

Recommendations.

Dr. Cates concludes: (1) That from the public health point of view there is reason for thinking that the total number of beds in the voluntary hospitals in Surrey is insufficient. His other main conclusions are summed up as follows by the Committee and accepted by them:—

(2) That there is a marked deficiency in hospital accommodation for women and children, and in facilities for treatment of diseases of the eye, ear, nose, and throat.

(3) That while recognising the valuable work done by the smaller hospitals, the piecemeal extension of small and unsuitable buildings, not originally planned

for use as hospitals, is to be deprecated, as hospitals so housed are difficult to administer economically.

(4) That medical work should be gradually concentrated in larger and better equipped institutions, which are more economical to administer, attract a better qualified and more efficient staff, provide for all types of diseases and defects, and, besides admitting maternity patients, give scope for eye, ear, nose, throat, and X ray specialists. Moreover, such hospitals can be self-contained and act as training centres for nurses and students, and can provide sufficient work for a motor ambulance service, thus enabling the hospital to supply the needs of a larger area.

(5) That general hospitals of this type are required in the western, south-eastern, and possibly in the northern portions of the county area—viz., at Guildford, Reigate or Redhill, and perhaps Surbiton or Epsom respectively.

Sundry Points.

Grants.—As the result of inquiry it was ascertained that only 9 out of 32 hospitals had applied for grants, and that the remaining 23 had reported either that they did not need any assistance from public funds or that they did not feel justified in asking for it. The applications of four hospitals were approved by the Committee, and certain grants were sanctioned by the Voluntary Hospitals Commission on the recommendation of the Committee.

Schemes for Extension.—The advice of the Committee was sought as to schemes for extension or rebuilding of various hospitals in Surrey and was appreciated by the hospital committees.

Accounts.—Stress has been laid by the Committee on the importance of adopting a uniform system of accounts.

Conflicting Appeals.—The attention of the Committee had been called to the question of conflicting appeals. The formation of a central fund for provincial hospitals on the lines of King Edward's Hospital Fund for London, as proposed in the annual report for 1922 issued by the Joint Committee of the Order of St. John and the British Red Cross Society, was considered likely to be a useful method of avoiding competition and overlapping.

Finance.—The administrative expenses of the Committee during the past year, which have been met by the grants from the Surrey County Council and Croydon Borough Council, of £50 and £20 respectively, are estimated at £30, including the cost of the report, leaving a balance of £40.

THE WORK OF THE PENSIONS MEDICAL SERVICE.

II.* TREATMENT OF PENSIONED DISABILITY.

In a foregoing article we dealt with the medical arrangements for determining the grounds on which are based the right to pension and the amount to be awarded. There are, however, other and many benefits for which the war-disabled, as occasion arises, are eligible.

Health, Training, and Employment.

Treatment for pensioned disability at the cost of the State includes all forms of in-patient, out-patient, and home-treatment, the supply and repair of artificial limbs and surgical appliances, and concurrent treatment and training. Under the provisions of the Naval and Military War Pensions Act of 1915 it became a function of the Statutory Committee of the Royal Patriotic Fund Corporation "to make provision for the care of disabled officers and men after they have left the service, including provision for their health, training, and employment"; the Act of 1916 creating a Ministry of Pensions placed the Minister in control of the Statutory Committee for the purposes of health, training, and employment; the Naval and Military

* Part I. appeared in THE LANCET of May 5th, p. 918.

War Pensions Act of 1917 dissolved the Statutory Committee and made the Minister directly responsible for all three functions; and finally the Ministry of Labour (Transfer of Powers) Order in Council in 1919 transferred training and employment to the Ministry of Labour except as regards officers and men whose training or employment, by reason of their war disability, required medical supervision or could not be carried out under ordinary industrial conditions.

Treatment Allowances.

The Royal Warrants define the conditions under which the Minister may incur certain expenditures, Art. 6 of the Warrant laying down the conditions which apply to cost of treatment and treatment allowances, or in other words the conditions of eligibility for these benefits. The procedure to be followed is set forth in detailed Ministerial instructions which differ in one important respect from the "Directions for the Guidance of Chairmen and Members of Medical Boards." These "directions," which are concerned with entitlement and assessment, request of the boards their free and unfettered opinion; whereas the "instructions" deal with procedure, the provision and cost of treatment, and the like, and are mandatory. Owing to the extraordinary variety of circumstance and case constantly arising, and to the involved relations of the medical department of the Ministry with the awarding, finance, and other branches, these instructions are so intricate that they can be successfully administered only by whole-time servants of the department. On this account the Ministry has created a whole-time medical service comprising at the present time 289 medico-administrative officials.

Nice Points for Determination.

The first point for determination is that the treatment recommended—whether by medical referee, medical board, or medical attendant—is for the pensioned disability. The Warrant lays down that where it is certified that a disabled man to whom a pension, gratuity, or final weekly allowance has been awarded, should in consequence of his disablement undergo any course of medical treatment and is deemed unable in consequence—that is, in consequence of his having to undergo a course of medical treatment—to provide for his own support and that of his family, "he may be granted, &c." No doubt, in many cases, simple documentary verification suffices to decide the question of eligibility for treatment; but where the pensioner requires treatment not for his disability in terms of, but "in consequence of" his disablement—and such cases now occur and will continue to do so in increasing number with mere efflux of time—questions arise demanding careful medical consideration.

Some Illustrations.—The questions for solution and the procedure following may be very different. For example, the man pensioned for nephritis who requires treatment for bronchitis is, naturally, in a very different position from the man pensioned for "myalgia" or "rheumatism" who is discovered to be suffering from *tabes dorsalis*. Indeed, in the latter case—which is, of course, a change of diagnosis—the originally conceded entitlement may be called in question and the case submitted to a medical board of reference. Again, of two men recommended for treatment for pulmonary tuberculosis, one pensioned for pleurisy with effusion and the other for bronchitis, one will have a much stronger claim to treatment and allowances at the cost of the State than the other, though in both substantiation by a medical board, following a fresh claim under Art. 9 of the Warrant, may be required. Examples of the nice points for determination which arise either as consequential disabilities or as changes of diagnosis might be quoted without end. Each calls, and often urgently, for treatment, and whilst everyone would deprecate too meticulous a dissection of any pensioner's disabilities—this disability being due to war service and that to post-discharge causes common to the civil population—it is evident that to hold the balance even requires a

strong combination of clinical knowledge and experience of departmental precedent and Ministerial procedure. Every medical referee, member of a Ministry clinic, or hospital, shares in this responsibility, which officially falls to the deputy commissioner in medical charge of an area of the Ministry, whose approval is required before any recommendation of treatment is carried out. Through the close and friendly relations which subsist between these officials and the members of boards and clinics, a difficult task is being harmoniously accomplished with ever-increasing efficiency and with no increase of time in securing to the pensioner the most appropriate form of treatment.

Misapprehension sometimes arises as to eligibility for treatment allowances. Treatment allowances are not payable as compensation for inability to work on account of the man's disability, this being a function of the pension awarded, but are payable only when in consequence of undergoing treatment a pensioner is unable thereby to follow his remunerative employment. In such circumstances the rate of pension, whatever that rate may be, is raised to the maximum or total disablement rate, and appropriate allowances are made in respect of the man's wife and children.

Extent and Variety of Treatment.

Accurate statistics of the earlier years of the Ministry prior to its regional formation or reformation, are not readily available, but we are informed that during the year 1920, excluding pensioners suffering from tuberculosis and also ex-service men in asylums, more than 115,000 men received in-patient treatment either at the hand or at the cost of the Ministry, and over 250,000 out-patient treatment. During 1921 the in-patients numbered 105,000 and the out-patients over 258,000, whilst in the year 1922 the in-patients treated amounted to more than 85,000, and the out-patients 204,000. In round figures, therefore, some 264,000 in-patients were treated during these three years, as well as 531,000 out-patients, apart from officers and nurses. These figures do not include some 40,000 patients treated in sanatoria for tuberculosis during these three years on behalf of the Ministry of Pensions, nor the insane ex-service men in asylums who to-day number some 6000.

Special Hospitals.—Full use has been made of civil medical resources, mostly in the form of payment on a capitation basis coupled with a certain degree of supervision and control by the medical department of the Ministry; but early in the year 1919 it became apparent that for special purposes, particularly in cases of neurasthenia, special surgical, tropical and cardiological cases, and also certain cases of epilepsy, the Ministry should organise, maintain, and control the means of treatment. Ministry hospitals were therefore established in every region for these special cases. At the present time there are 37 such institutions with 10,047 beds. Of these institutions nine are for neurasthenic patients, and eight others have neurological sections. There is also one hospital with 300 beds reserved for epileptic cases. The total number of beds specially set apart in Ministry hospitals for special cases are: Neurasthenia, 2924; epilepsy, 300; dysentery, 235; limb-fitting, 161; general surgical, 4125. During 1922 more than 50,000 in-patients were treated in these hospitals. The Ministry has also established under its direct control a large number of special clinics, each administered by the D.C.M.S. of the area and staffed by approved specialists in their vicinity. These clinics not only give out-patient treatment, but carry out the duties otherwise discharged by medical referees.

No account of the treatment of the pensioner would be complete without mention of the work in connexion with the limbless at Queen Mary's Auxiliary Hospital at Roehampton, and a considerable number of limb-fitting centres distributed throughout the country, and of the important and profoundly interesting work of concurrent treatment and training. For pensions purposes everything that affects a man's disability is of importance and must be to some extent reflected in his pension.

ROYAL MEDICAL BENEVOLENT FUND:

ANNUAL MEETING, MAY 7TH.

THE annual meeting of the Fund was held this year in the Library of the Royal College of Physicians of London in order to mark the urgent nature of the appeal for the relief of distress within the medical profession.

Sir Thomas Barlow, the President of the Fund, in opening the proceedings summarised the objects and present position of the Fund—this has already been set out in THE LANCET of April 28th (p. 860)—and expressed the hope that every medical man in the country would take his share in relieving the burden of less fortunate fellow members, and that the larger public which appreciated its debt to the medical profession would help towards the same end. The financial statement and the report were then taken as read.

The Archbishop of Canterbury, in moving their adoption, said that laymen had only rare opportunities of expressing in a public manner their sense of the value of the services rendered to the whole community by the medical profession. Opportunities often occurred for cheering politicians, soldiers, and sailors, but he hardly knew of a single instance where the object of a gathering had been to cheer medical men. It was the duty of the public to help the medical profession in its difficulties and troubles in meeting the special emergencies due to hard times, for there was, perhaps, no class of the population upon whom the indirect results of the war pressed more heavily.

Lord Sumner, who seconded, said that the medical profession which was engaged in beneficent work found it difficult to put before the public their own needs, while the nature of the duties of that profession and the time occupied in performing them often precluded the medical man from making successful employment of the money he had, and from making adequate provision for the future. The working-classes were willing to make proper contributions in respect of medical assistance they received, and he thought that trade-unions might be appealed to for annual subscriptions to the Fund.

Sir Humphry Rolleston said that the medical profession was a relatively short-lived one, and many medical men were unable to make adequate provision for old age. Cases had come before the Fund where there were no means at all except the Old Age Pension. It was the duty of every medical man, according to his ability, to subscribe to the Fund, which at present received the support of only 7 per cent. of more than 7000 medical practitioners within the metropolitan area.

The financial statement and the report were then adopted unanimously.

Among those present at the meeting were Sir David Ferrier, Sir Dyce Duckworth, Sir William Hale-White, Sir Charters Symonds, Dr. Newton Pitt, Dr. Herbert Spencer, Dr. Arnold Chaplin, and Dr. J. H. Stowers.

STANDARDISED CONDENSED MILK.

THE Ministry of Health has made Regulations,¹ dated May 1st, under the Public Health (Regulations as to Food) Act, 1907, and the Milk and Dairies (Amendment) Act, 1922, entitled "The Public Health (Condensed Milk) Regulations, 1923," and has issued a circular² on the subject dated May 4th. The Regulations provide for a uniform method of labelling all tins containing condensed milk or condensed skimmed milk, whether sweetened or unsweetened, and specify the composition of the different varieties of condensed milk in terms of milk solids.

¹ Statutory Rules and Orders, 1923, No. 509, H.M. Stationery Office, price 2d.

² Circular 393, H.M. Stationery Office, price 1d.

Labelling.—All condensed milk is to be labelled with one of the four following declarations:—

CONDENSED FULL CREAM MILK,
UNSWEETENED.
THIS TIN CONTAINS THE EQUIVALENT OF
(a) PINTS OF MILK.

CONDENSED FULL CREAM MILK,
SWEETENED.
THIS TIN CONTAINS THE EQUIVALENT OF
(a) PINTS OF MILK, WITH SUGAR ADDED.

CONDENSED MACHINE-SKIMMED MILK
[or CONDENSED SKIMMED MILK],
UNSWEETENED.
UNFIT FOR BABIES.
THIS TIN CONTAINS THE EQUIVALENT OF
(a) PINTS OF SKIMMED MILK.

CONDENSED MACHINE-SKIMMED MILK
[or CONDENSED SKIMMED MILK],
SWEETENED.
UNFIT FOR BABIES.
THIS TIN CONTAINS THE EQUIVALENT OF
(a) PINTS OF SKIMMED MILK, WITH SUGAR ADDED.

The declaration is to be printed in dark block type of prescribed size on a light ground within a surrounding line which must contain no other printed matter. The label must also bear the name and address of the manufacturer or the dealer in the United Kingdom for whom it is manufactured. It is forbidden to place on the tin any comment, explanation, or reference in regard to the statement of equivalence, or to the words "machine skimmed," "skimmed," or "unfit for babies," or any instructions as to dilution unless they clearly specify that the resultant fluid is not of equivalent composition to milk or skimmed milk, or unless the resultant fluid corresponds in milk solids to milk of the standard set by the Regulations (see below). Wherever the word "Milk" appears on a tin containing condensed skimmed milk it is to be qualified with the words "Machine-skimmed" or "Skimmed." The statement of equivalence on the label is to be expressed in pints and fractions of a pint, and is to be in terms of milk containing not less than 12.4 per cent. of milk solids (including not less than 3.6 per cent. of milk fat), and skimmed milk containing not less than 9 per cent. of milk solids other than fat.

Composition of Condensed Milk.—The Regulations set the following standards:—

Description of condensed milk.	Percentage of milk fat.	Percentage of all milk solids, including fat.
Full cream, unsweetened ..	9.0	31.0
Full cream, sweetened ..	9.0	31.0
Skimmed, unsweetened ..	—	20.0
Skimmed, sweetened ..	—	26.0

The Regulations are to be enforced by the local authorities who have the appointment of public analysts, and the procedure of the Sale of Food and Drugs Acts in detecting and dealing with contraventions will be followed. At ports of importation the Regulations will be executed by the Customs authorities. Contraventions of the Regulations render the offender liable to a penalty not exceeding £100, and not exceeding £50 a day in the case of continuing offences.

All those interested in child welfare will welcome provisions which standardise the composition of condensed milk, and ensure that the purchaser obtains full information as to the value of the article bought. The Regulations are a useful check to misleading descriptions, which might with advantage be applied to many other foodstuffs.

Public Health Services.

THE HEALTH OF CAPE TOWN.

THE annual report of Dr. A. Jasper Anderson, the medical officer of health for the City of Capetown, for the 12 months ended June 30th, 1922, constitutes an interesting record of the health of a considerable community of European race living under climatic conditions differing appreciably from those of English towns and side by side with a native African population. An indication of the climate during the year under review is afforded by the following records. In the hottest month, February, the mean maximum and minimum temperatures were 83.5° and 58.6° F., the highest and lowest readings being 96.4° and 48.9°, while in the coldest month, July, the mean maximum and minimum were 62.1° and 44.9°, the extreme readings being 75.5° and 38.0°. The earth temperature at a depth of four feet varied from 54.5° in August to 69.1° in March, and the rainfall for the year amounted to 24.15 inches. The hours of bright sunshine during the eight months October to May averaged 8.5 per diem. The influence of the varying seasons on health conditions would not appear to be great, the greatest number of European deaths in any one month (June) being 116, and the smallest (January) being 91. Next for mortality to the winter month of June came the summer month of February.

The population of Capetown is 186,050 and comprises 103,520 Europeans and 82,530 non-Europeans. From the statistics submitted by Dr. Anderson we select the following:—

	European.		Non-European.	
	1913-14	1921-22	1913-14	1921-22
Population	76,940	103,520	74,560	82,530
Birth-rate	29.39	24.21	45.48	51.64
Death-rate	13.77	11.88	28.25	27.46
Infantile mortality rate.	107.96	69.03	250.54	176.44
Tuberculosis death-rate.	1.35	1.04	5.11	3.71

The European death-rate was lower than in any former year. When deaths of visitors are excluded (for Capetown is a favourite holiday resort in South Africa) the rate is only 10.63. The infantile mortality rate was much the lowest ever recorded, and the course of the mortality rates amongst Europeans must be a matter of gratification to those responsible for the health services of the city, and particularly for Dr. Anderson, who is so soon bringing to a close his long term of office as medical officer of health. His place, as we have already announced, will be taken by Dr. T. Shadick Higgins, medical officer of health for St. Pancras. The figures also show that the healthiness of Capetown compares favourably with that of English towns. The state of affairs amongst the non-Europeans is very different.

The city was fortunate in regard to most of the zymotic diseases during the year. There were no deaths at all from small-pox, measles, and scarlet fever, and, amongst Europeans, none from whooping-cough. There were 115 European cases of diphtheria (9 deaths). Enteric fever is the most troublesome of the zymotic diseases. Amongst Europeans it caused 260 cases with 27 deaths and amongst non-Europeans 244 cases with 46 deaths. There has already been an improvement in regard to enteric, and Dr. Anderson expresses the hope that it will be further reduced by the sewerage of the suburbs which is proceeding rapidly. Malaria and tropical diseases are conspicuous

by their absence. The year's work of the health department includes 627 admissions to the city hospital, 15,097 attendances at the maternity and child welfare "bureaux," 1034 at the tuberculosis "bureau," and 8574 attendances at the venereal clinic. The report discloses that there are legal powers at Capetown for dealing with matters that might well be given more attention in this country. These include the licensing of butchers, vendors of fruit and vegetables, general dealers, hawkers, bakers, ice-cream sellers, hairdressers, mattress-makers, laundries, and bioscope entertainments.

SCHOOL MEDICAL SERVICE.

Sheffield.

DURING 1922, in spite of a reduction in medical staff, over 24,000 children underwent medical examination, and of these 19.5 were found to have one or more defects requiring treatment. For 95.2 per cent. of these treatment was obtained. Four of the schools have special rooms adapted to medical treatment, and school clinics are open all the year round without a break. The babies from the Maternity and Child Welfare Centre also make use of the school clinics for treatment. The total number of children dealt with here suffering from minor ailments was 6214. "The provision which the committee have been able to make for the dental needs of the school population is, unfortunately, totally inadequate. However, although there are thousands of children receiving no dental treatment at all, a larger proportion every year are availing themselves of the treatment." Dr. Thomas Chetwood reports that in the majority of cases of enlarged tonsils and adenoids, operative interference was not indicated; "in fact, much improvement may be expected from simpler forms of treatment." Over 900 children were found suffering from partial or complete deafness, and about 500 had some form of ear disease. A general increase of interest in crippling defects has resulted in extended facilities for orthopaedic treatment; 35 such cases were treated during 1922, 23 of these being discharged before the end of the year. Unfortunately, classes for dull and backward children have not yet been established in this city. The two open-air schools are doing good work, and extension of both has been recommended. The children continue to do well, although the problem of procuring sufficient and suitable clothing is an ever-present one in spite of the generosity of teachers and the public. Indeed, the question of the quality, suitability, and cleanliness of school-children's clothing generally is a very serious one.

In the special inquiry by one of the assistant medical officers into the incidence of tuberculosis in elementary schools we find "unsatisfactory footgear implies poverty, and, as might be expected, the schools where the children are worse shod show a high rate of incidence." In spite of the fact that returns show a slight improvement in cleanliness and footgear during routine inspection it is evident that the chief superintendent of physical training, in his excellent appendix at the end of this report, comes nearer the mark when he says, "the quality of the clothing is rapidly deteriorating in poor districts owing to the distressing continuance of unemployment." It must be remembered that the standard of cleanliness at medical inspections is a spurious one. A school medical officer recently drew attention to the fact that unemployment and uncleanness go hand in hand. He reported that depression in the labour market is always reflected in an increase of uncleanness among school-children, just as periods of prosperity are marked by an improvement, not only in nutrition and clothing, but also in cleanliness, and school nurses working among large numbers of children will bear him out on this point. Another school doctor commenting on the increase of uncleanness among school-children attributes the condition to "an apathy produced by unemployment that needed a more substantial remedy than moral persuasion." The whole question of cleanliness is a

question of pounds, shillings, and pence. Cleanliness means coal; coal means money. Cleanliness of home and clothing cannot be attained without hot water, a commodity inaccessible to the poorer classes without coal. The whole question of the comfort of the working classes inevitably revolves round hot water, or, in other words, coal. Money is spent first on the necessities of life, food and the means of cooking it, and only the surplus after this is deducted is spent on cleanliness either of clothing or body. Consequently cleanliness inevitably varies inversely with prosperity. Poverty primarily shows its effect on cleanliness, and eventually on nutrition. It is unfortunate, then, that at a period of unemployment such as this, Sheffield should find it necessary in the interests of economy to close the school baths. Three of the four school baths have been closed, and as Dr. Chetwood, who deplores such a measure, points out, the facilities for bathing at home are sadly lacking. By removing the facilities at school, small as they were, the education authority connects up, as this report demonstrates, a vicious circle of uncleanness, neglect, and disease.

The superintendent of physical training, commenting on the development of school games in the elementary schools, recalls the fact that some years ago the number of games played in most school playgrounds was under ten. Often the same games were played by seniors and juniors alike, most of them being too hard for the juniors and too easy for the seniors; now most teachers arrange a progressive syllabus of games. The value of this for the mental development of the child, apart from its effect on his physical development, is obvious. The number of sports clubs connected with the city is rapidly developing, which goes to point out that the early training is bearing fruit, and the young men and women are becoming players instead of merely watchers.

Shrewsbury.

In this compact report of work done Dr. Gordon Smith remarks that the number of cases examined under the code groups is not large enough to form a basis for statistics, but is quite large enough to give a general indication of the conditions prevailing among school-children. The results of medical examination vary considerably with the home environment of the child, bearing out to a large extent what has been actually proved by the nutrition clinics in America. The percentage of dirty and verminous children in Shrewsbury has increased, and the school medical officer attributes this to loss of self-respect among parents and children owing to bad housing conditions, unemployment, and consequent scarcity of food. The clothing and footgear of the children have suffered, too, in spite of the fact that the borough police have given away hundreds of pairs of boots to necessitous children. Impetigo and ringworm have increased considerably as a natural consequence of poverty following upon unemployment. Dr. Smith notes also that the percentage of dull children has increased, and suggests that the lack of food and proper attention is reacting upon the mental condition of the children. Bronchial catarrh, a common enough condition among children badly fed and housed, also shows an increase. Out of 1249 children inspected at routine inspections, 126 were suffering from malnutrition. Out of the 93 children requiring treatment, 60 availed themselves of the ample facilities provided for treatment. Parents appear to object very little now to having operative treatment for enlarged tonsils and adenoids, but they have not yet grasped the importance of having defective eyesight remedied. The question of dental treatment, too, raises few objections, and 257 children were treated by the school dentist, only 21 failing to attend. Dr. Smith attributes the success of the dental clinic to the school dentist, who has done much to popularise the clinic by his gentle way with the children. A plea is put forward for special consideration for mental defectives, most of whom attend the elementary school, where they handicap both teachers and taught.

Gillingham (Kent).

During the year 3857 children were medically inspected, 2253 coming under the code groups. There was not one case of malnutrition found, and only one of rickets, although 315 special cases were found to have unclean heads. After routine inspection 365 were found to require treatment, and 83 special observation; 210 received treatment. Disease of nose and throat accounted for 118 children requiring treatment, and defective vision for 107. Gillingham is a healthy borough for children. In addition to the practical absence of malnutrition and rickets, there was not one case of defective hearing recorded, although routine inspection revealed 65 with ear disease; nor was there apparently a single case of eye disease, or of enlarged cervical glands (non-tuberculous), although 114 were found on routine inspection to have enlarged tonsils and adenoids, and medical inspection revealed 120 cases of dental caries. After the dental inspection of 2055 children, 366 were referred for treatment, 214 of these being treated. Dr. W. A. Muir, who was appointed school medical officer as recently as September, 1922, as successor to Dr. E. C. Warren, puts on record his indebtedness to the school nurses in carrying on the work of the department.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Comdr. D. P. Chapman is placed on the ret'd. list at his own request.

Surg.-Lt. J. S. McGrath to be Surgeon Lt.-Comdr.

ROYAL ARMY MEDICAL CORPS.

Lt.-Col. and Bt. Col. J. S. Bostock is restd. to the estab't. Maj. J. W. Kynaston, on relegation to the ret'd. list, is granted the rank of Lt.-Col.

TERRITORIAL ARMY.

Cpts. J. B. Orr and J. C. Knox (late R.A.M.C.) to be Cpts.

Capt. J. A. Mathers resigns his commn. and retains the rank of Capt.; and Lt. D. R. Wheeler resigns his commn. and retains the rank of Lt.

The undermentioned relinquish their commns.: Temp. Capt. O. W. Gange, and retains the rank of Capt.; Temp. Hon. Capt. H. A. Haskell, and retains the hon. rank of Capt.

General Hospitals: Capt. B. A. Lloyd relinquishes his commn. and retains the rank of Capt.

The undermentioned, having attained the age limit, are retired and retain their rank, except where otherwise stated. Lt.-Cols. Sir J. Barr and A. B. Gemmel (Bt. Col.), F. A. Southam; Maj. F. T. Paul, R. W. Murray, J. Utting, P. Davidson, J. M. Beattie, and R. A. Bickersteth; Cpts. J. R. Logan, J. M. Hunt (granted the rank of Lt.-Col.), F. C. Larkin, D. Douglas-Crawford, J. L. Roberts, C. T. Holland (granted the rank of Maj.), R. J. McL. Buchanan, W. Finland, J. Hay (granted the rank of Lt.-Col.), T. R. W. Armour (granted the rank of Maj.), L. A. Morgan, K. W. Monsarrat (Bt. Maj.) TERRITORIAL ARMY RESERVE.

Majs. R. Griffith (Bt. Lt.-Col.) and W. D. Sturrock from Gen. List, to be Lt.-Cols.

Maj. G. A. C. Shipmen, from 4th Northern Gen. Hospital to be Maj.

Capt. J. G. Morrin, from Gen. List, to be Capt.

Capt. F. G. Armstrong, from 1st Northern Gen. Hospital to be Capt.

DONATIONS AND BEQUESTS.—Dr. Donald Peter MacLaren Farquharson, medical officer of health for Radcliffe, left £1000 in trust for the clothing of necessitous Radcliffe school-children, and for sending the delicate one to the seaside.—Towards the Lord Mayor's appeal for 2,000,000 shillings for the hospitals and infirmaries of Manchester, Salford and District, a first list of donations published showing subscriptions received or promised amounting to £20,000.

Correspondence.

"Audi alteram partem."

SERUM DOSAGE IN DIPHTHERIA.

To the Editor of THE LANCET.

SIR,—I have read with interest Dr. C. B. Ker's paper and the instructive correspondence that has ensued. In the main I agree with Dr. Ker's views and approve of his method of dosage. I cannot see, as some seem to think, that he has done anything very wrong when he advises smaller initial doses, say of 4000 units, for milder attacks, and 8000 for severer forms. Personally, I have used doses of these amounts, and have never varied them, for the last 20 years, and the death-rate in this hospital will compare favourably with that of any other, although for the last two years it has shown a tendency to rise. But, if there is any doubt about the practitioner not being able to distinguish in the early stages the mild from the malignant cases, then it seems to me that that difficulty can be got over by advising initial doses of 8000 in all cases. But there is no need that the hospital medical officer should follow suit. He can, as the result of his experience, distinguish the malignant from the mild forms of attack, so that there is no reason why he should not decide upon the smaller dose. In the past heroic doses have been given which, it is now generally recognised in this country, do not accomplish more than the moderate doses such as Dr. Ker advises. As regards the method of administration, I have found no very marked benefit from the intravenous route.

With Dr. E. W. Goodall's assertion that "if patients are brought under treatment early—that is, on the first or second day of disease—they nearly all recover," I am afraid I cannot agree. My experience is that in the virulent forms of present-day attacks the chances of recovery from the very onset are of the poorest. I entirely agreed with regard to Dr. B. A. Peters's statement that diphtheria has suddenly altered in type in recent years. It has been noticeable in this district since 1920, and, as a matter of fact, I drew attention to its increased severity in my annual report for that year.

But, before going any further into this matter of dosage, would it not be as well to look at the whole question from a different point of view. Have we not got to that stage where we might ask: "Is diphtheria antitoxin all that we believe it to be?" I myself think there is reason to doubt it. Certainly many fatal cases which have been admitted to this hospital in recent years, several of which came in on the first and second day of disease and were given antitoxin intravenously, endorse this view. No doubt most would attribute the fatal issues in these cases to the exceptional virulence of the attacks, and that very likely is so; at the same time we ought not to forget that possibly the real cause was the fact that the antitoxic value of the serum was relatively low. I understand that diphtheria antitoxin is standardised by testing its power on guinea-pigs against the toxin of the most virulent culture of diphtheria organisms that can be obtained from any part of the world. This culture comes from New York and has been in use for over 15 years. Is there any evidence that this culture is of the same strain, or that it equals the virulence of some of the infections present in malignant attacks now so common in certain parts of this country, or that as the result of subculture over such a period of years this New York organism has not undergone material change?

Recent investigations with regard to the pneumococcus show that there is more than one strain of this organism and that each requires its own antiserum, the active principle of which is possibly an antitoxin. Similarly, clinical experience indicates that there is more than one strain in diphtheria, and, if it is so, might it not be that these different organisms produce

toxins different in virulence and different in their serological reactions, and that for their neutralisation they require different antitoxins. If this is the case, does it not explain the failure of present-day antitoxin to deal alike with mild and severe attacks of this disease, and does it not suggest the lines of preparation along which the manufacture of our standard antiphtheritic sera must take. In other words, we require a composite serum which will counteract the toxin of all strains.

Presuming that it is possible to prepare a serum of this nature, and I am anxious to try a serum made from local strains, I think it would clear up the whole question of dosage and help to remove the divergence of opinion which seems to prevail in connexion with the amount of the initial dose.

I am, Sir, yours faithfully,

W. J. J. STEWART.

Municipal Hospital, Neasden, N.W., April 23rd, 1923.

To the Editor of THE LANCET.

SIR,—May I be permitted to add my quota of experience, small though it may have been compared with that of those who have already expressed themselves in these columns. I would confine myself to a few remarks on the serum treatment of naso-pharyngeal diphtheria, based on a short series of cases met with during the winter 1920–21 at the Croydon Borough Isolation Hospital. In view of the high mortality usually noticed in this type of case it was decided to submit a series of some thirty cases to intravenously given serum. This series comprised practically all such cases met with during the period in question, no special case selection taking place. The procedure consisted in giving each case as soon as possible after admission 8000 to 10,000 units of heated antitoxin intravenously, though later on in the series half that amount of serum which had been given intravenously was also given intramuscularly. The results were, from the beginning, almost striking: membrane could be seen separating within an hour or two after injection, whilst a profuse nasal discharge dried up overnight. I would add a point, which appeared to me to be of some significance, that cases improved in proportion to the time of onset of reaction, a rigor at or soon after injection indicating a good prognosis. Fatal cases invariably failed to respond in this way.

The death-rate in the above unselected series was remarkably low—13.3—compared with that usually obtaining in this particularly virulent variety of the disease, which may be said to vary from 40 to 60 per cent. or upwards. Intravenous medication, I believe, necessary only in this type of diphtheria, combined to obtain the full benefit of treatment with intramuscular injections of smaller amounts of serum.

I am, Sir, yours faithfully,

K. SIMPSON, M.D.

Town Hall, Croydon, April 28th, 1923.

To the Editor of THE LANCET.

SIR,—Dr. C. B. Ker, in referring (THE LANCET, April 28th) to the severe type of diphtheria, of which Dr. B. A. Peters wrote, says: "I doubt very much if even 8000 units as advised by Dr. Thomson would do any more good than my own smaller doses." I am quite certain Dr. Ker has no desire to misquote me in saying this, but he has done so, for in my letter in your issue of April 7th my argument was that if 8000 units as a minimum dose was both safe and efficient, then certain results would follow. It was not I who said that 8000 units as a minimum dose was both safe and efficient, but Dr. Ker himself. In his note on serum dosage in diphtheria, in your issue of March 31st, he says: "The advisers of the Ministry of Health recommend that a dose of 8000 units should be given immediately in any case provisionally diagnosed as diphtheria. We may admit at once that such a procedure is both safe and efficient."

In further reference to the very severe type of diphtheria to which Dr. Peters refers, Dr. Ker says

he thinks serum does as little good in such cases as it does in the hæmorrhagic type, which, even if treated early, seems invariably to be fatal. I cannot understand how Dr. Ker makes such a statement, and I can only hope I have mistaken his meaning, for in my experience the very severe form of diphtheria referred to by Dr. Peters almost invariably recovers if treated with adequate doses on the first day of the disease. By adequate doses I do not mean 10,000 or 15,000 units, but 30,000 up to 60,000 units.

I am, Sir, yours faithfully,

FREDERIC THOMSON.

North-Eastern Hospital, S. Tottenham, April 28th, 1923.

To the Editor of THE LANCET.

SIR,—May I say in reply to Dr. F. E. Tylecote that, although I formerly gave larger doses to patients admitted late in the disease, it is difficult to see what can be gained by such a procedure if we cannot hope to detach toxin which has entered into combination with tissue. Even when large doses are given the death-rate rises with each day that the first dose has been delayed, which seems to suggest that the damage done in the early days is irreparable. It is very difficult to estimate the severity of different types of disease in different places and comparison is almost impossible. All I can say is that our death-rate in Edinburgh has varied of late years much as that of Dr. Peters in Bristol. For the last two years it has been only $6\frac{1}{2}$ per cent; before that it varied from 8 to 10 per cent. for some years. But perhaps this may be attributed to under-dosage, although our severe cases receive, as a rule, 40,000 units within about 24 hours of admission. I cannot help feeling that many of us give large doses because we are afraid to give small ones, and yet the difference in results from the days of the small dose is very slight, as all who witnessed the introduction of antitoxin treatment will, I think, frankly acknowledge.

I am, Sir, yours faithfully,

CLAUDE B. KER.

City Hospital, Edinburgh, April 27th, 1923.

FOURTH INTERNATIONAL CONGRESS OF REFRIGERATION.

To the Editor of THE LANCET.

SIR,—As secretary of the Papers Committee, Commission I. of the Fourth International Congress of Refrigeration, I have been requested to approach you with the object of obtaining your assistance to get into touch with members of the medical profession who would be willing to contribute any papers on the uses of artificially produced cold with regard to medical research and practice. The following is a list of subjects to be discussed at the Congress:

Verification of experiments undertaken before the war by the Russian scientist, Bakhmetieff, relating to the action of cold on living organisms. Cryotherapy in the treatment of certain skin diseases. Use of refrigeration in anatomy. The action of refrigeration for the amelioration of opotherapy; corresponding refrigerating installations. Biological study of milk preservation by refrigeration; bacteriology of ice-cream. Biological study of chilled and frozen produce (meat, fish, eggs, vegetables, fruits, &c.). Use of frozen eggs in food preparation; bacteriological examination. Refrigeration by the circulation of defibrinated blood. Refrigerating installations in hospitals and dwelling-houses. Operation and maintenance of refrigerating installations from the point of view of health and hygiene. Handling of frozen produce. Moulds in cold stores, and the means of combating them. Moulds in meats and other frozen produce. In addition, Mr. d'Arsonval proposes to contribute a report on the Preservation of Serums and Vaccines by Refrigeration.

Any help you could give in the matter would be highly appreciated. The Congress is to take place in London about June, 1924.

I am, Sir, yours faithfully,

JOHN D. FARMER.

Dartford Iron Works, Dartford, Kent, May 3rd, 1923.

L'AFFAIRE SPAHLINGER.

To the Editor of THE LANCET.

SIR,—Beginning in 1915, I treated, with Mr. Henry Spahlinger's method, 294 cases of tuberculosis, mostly pulmonary. The serum was used in 189 cases and the vaccine in 105 cases of a less acute type. These patients had not responded to ordinary methods of treatment. It has been difficult to compile exact statistics for the following reasons: (1) I have had to work only with partial sera and partial vaccines; (2) these were intermittently supplied; (3) during certain periods I have been obliged to use sera three or four years old; (4) in order to economise the antitoxins, so difficult to secure, I have often employed them during only a short period, to check acute symptoms or to arrest a new outbreak or a rapid extension of the disease; (5) supplies were too limited and frequently insufficient for the prolonged treatment necessary for the very grave cases I had in hand. The result was that patients have often left much improved instead of being clinically cured, as would probably have been the result if I could have continued the intensive treatment. Under these conditions it is evident that statistics cannot show the real value of Mr. Spahlinger's two specifics.

In 1919–20 I selected from 300 sick Russian prisoners 50 very severe cases, most of them suffering from pulmonary tuberculosis, some complicated by secondary tuberculous lesions of the larynx, abdomen, and joints. With a fairly complete series of fresh partial sera then available I obtained 82 per cent. of recoveries, enabling the patients to return to work, 12 per cent. remained stationary, and 6 per cent. died. Of the 189 severe cases treated with partial serum 80 per cent. show favourable results (complete recoveries or arrest of the disease). Of the 105 cases of a less acute type, who were treated with partial vaccines, 77 per cent. were cured or much improved and 23 per cent. little or not influenced. It is important to note that the vaccines were employed only when the evolution of the disease had not responded to the ordinary methods of treatment, including aërotherapy and altitude. Therefore taking the whole of the 294 cases, the positive results are: 80 per cent. for the serum and 77 per cent. for the vaccine.

Statistics compiled under the difficulties to which I have referred are possibly of less value than observations made from study of cases such as those which I append. My experiences clearly demonstrate the importance of a large polyvalence, requiring over 20 different partial sera, the combination of which is found to be indispensable in order to treat with success the different toxic manifestations of the disease. I have employed in the treatment of my patients three different types of partial antituberculous sera: antitoxic, anti-endotoxic, and antibacterial, all three polyvalent. In advanced or acute cases of tuberculosis antitoxins are required in order to neutralise the toxins and to support, by passive antitoxic immunity, an organism which cannot sufficiently defend itself. Symptoms of intoxication such as pyrexia, profuse perspiration, vomiting, anorexia, &c., I have found to yield in a few weeks if the patient's resisting power can be supported with sufficient polyvalent antitoxin.

Surgical cases are most successfully treated with a mixture of anti-endotoxic and antibacterial sera. They induce a much more rapid recovery than other treatments, such as the sun-cure. It is of advantage to inject the surgical sera directly into the foci. Numerous experiences have shown that the antibodies do not invariably suffer from alteration through the gastric juices when taken by mouth fasting. I have found that serum given by mouth during the night is most effective in some cases of tuberculosis of the intestines, while other similar cases do not appear to respond to the treatment by mouth.

When a partial serum (for instance, No. 2) which in certain cases, produces favourable results was replaced by another partial serum (for instance

No. 3), even if chosen from the same type such as antitoxins, the patient at once stopped improving and the progression of improvement only recommenced when the successful serum No. 2, which was first employed, was resumed. Yet the ineffective partial serum No. 3 had given most beneficial results in other forms of tuberculosis. These experiences have been made many times with the different partial sera, and they establish the importance of the polyvalence of the serum.

I have never had the complete vaccines, as used in 1913-14; only partial vaccines have been at my disposal. The patients who have recovered by means of these partial vaccines cannot be considered as immunised and thus prevented from any relapse. I have come to the conclusion, however, that Spahlinger's partial vaccines produce undeniable curative effects. They are most helpful in completing the recoveries of patients who, with the assistance of the serum, have overcome an acute condition. I have used the partial vaccines alone in afebrile pulmonary and in all forms of surgical tuberculosis. The temperature reactions, which sometimes take place immediately after the injections (especially after the strong solutions), are harmless and quickly disappear. These vaccines have never produced a flare-up of the disease with lasting high temperature.

It should be noted here that surgical cases can be successfully treated either by anti-endotoxic and antibacterial sera, or by vaccine. The immediate results of the serum, especially when injected in or near the tuberculous lesions, are more rapid; but there is always a possibility of recurrence of the morbid symptoms after the treatment has been stopped. With vaccine the improvement does not commence so quickly and only becomes noticeable when the patient has attained a certain degree of immunity. The results, however, are of a lasting nature. It is therefore advisable to treat surgical cases with vaccine alone when available.

Descriptive Cases.

CASE 1. *Mr. M. O.*—Affected with tuberculosis of the sternum, with large collection of pus. T.B.+. Had been operated upon in Germany three times without benefit. During the summer of 1919 I treated this patient for two and a half months with an all-day long sun-cure. At the beginning this big lesion appeared to close up superficially, but it was suppurating internally, and again we had to draw off the pus, proving that the sun-cure was ineffective. Following Mr. Spahlinger's suggestions I injected antibacterial partial serum Nos. 5 and 21 deep into the abscess itself and also into its periphery. This treatment was continued for a few weeks. It led to the gradual disappearance of the infiltrated foci, to the drying up of the fistulae, and effected a cure which proved to be of a lasting character.

CASE 2. *Mr. M. T.*—Patient had been suffering for a year with profuse hæmoptysis. In August, 1919, chest examination showed total infiltration of left lung and of right base, with acute softening of left apex. Also abdominal tuberculosis. No appetite, violent abdominal pains, vomiting, temperature 39°C., rapid emaciation (7 kilos during the last four weeks). T.B. in sputum and stools. His condition appeared too severe to permit of a therapeutic treatment being attempted. Nevertheless, I started injections of antitoxins, but as patient's condition was extremely critical I administered also by mouth a partial serum which had previously shown itself most efficacious for intestinal lesions. In one week vomiting and abdominal pains disappeared, temperature became normal. In a month and a half the weight had increased by 8 kilos and disease appeared to be arrested. The serum was then stopped, but pulmonary and abdominal symptoms reappeared gradually, and four months after they were acute once more. Serum treatment was resumed, and 20 days' treatment with the same partial serum, given by mouth, was necessary before the symptoms commenced to diminish. I then continued to give the serum by mouth and by injections without stopping, and by the end of 1920 a cure was obtained with a gain of 10 kilos in weight. Since then the recovery has been maintained.

CASE 3. *Mr. J. F.*—Had previously had sanatorium treatment, but with no definite results. Cavity at left apex with acute softening of the surrounding areas, massive infiltration throughout the whole of left lung, widely disseminated miliary disease in right lung, abdominal tuberculosis (violent pains, tympanism, vomiting), bilateral epididymis, with seven suppurating fistulae, lupus lesion on nose, high

temperature, pulse 129, numerous T.B. in sputum, very profuse night sweats, emaciation (2 st.), condition of collapse, all symptoms showing a generalisation of the disease. A fatal prognosis within a very short time was given by the physicians who examined him at that period. The Montana altitude treatment having failed to improve this patient, and his condition becoming rapidly worse, injections of three partial antitoxins were started in May, 1921. Injections of 2 c.cm. of a mixture of these three partial sera for 13 days reduced temperature to 38°C. This treatment was continued for a further period of 20 days and brought the temperature to normal. The T.B. number in sputum decreased in two months from 60 per cent. to 20 per cent., and in the following two months to 8 per cent. The antitoxic treatment had dried up the cavity and stopped the digestive troubles. The patient's weight increased by 9 kilos. The profuse suppuration from the bilateral epididymis having not been influenced by the antitoxins, antibacterial serum was then added to the antitoxins. It rapidly stopped the discharge and reduced by 75 per cent. the tumefaction of the testicles. The lupus lesion had disappeared. Five months after I added to the antitoxic and antibacterial sera some partial vaccine in order to create an active immunisation. This man, who was dying at Montana early in 1921, has now been working since the beginning of this year.

CASE 4. *Mr. H. J.*—Tuberculosis of the lungs since 12 years, with hæmoptysis and occasional rises of temperature. In 1920 I found a slight infiltration throughout left lung. Temperature normal; 2 or 3 T.B. per field. Patient debilitated. For ten months various treatments, such as creosote, tuberculin, Dr. Rous's angiolympe, and other supposed specifics, were tried to improve this stationary case, but unsuccessfully. I then tried Mr. Spahlinger's partial vaccines. Some of the injections were followed by a rise of temperature to 39°C., which lasted a short period, never exceeding 48 hours, without producing any alarming focal reactions. Gradually all symptoms of activity disappeared, and physical signs became quite dry. The occasional spells of pyrexia with stained sputum or hæmorrhages completely ceased, and the general condition became quite satisfactory. Seven months from the beginning of the vaccine treatment patient started work again, and the cure appears to be perfectly lasting.

I have had many similar cases. These partial vaccines, although they cannot protect a patient against a possible relapse, are very active in improving and curing chronic cases and in consolidating improvements obtained by means of the sera.

Basing my statement on 28 years' experience of tuberculosis and on the last eight years' work with Spahlinger's specifics, I come to the following conclusions:

- (a) The serum has a remarkable antitoxic action.
- (b) Each partial serum is effective in some form of tuberculosis.
- (c) A polyvalent serum is necessary to obtain a high percentage of recoveries in acute or advanced stages of the disease.
- (d) This serum treatment can be successfully applied to the most severe cases, when no other means could produce any results.
- (e) The partial vaccines have a marked curative effect.

I am, Sir, yours faithfully,

May 1st, 1923.

D. TH. STEPHANI.

THE TEACHING OF OBSTETRICS.

To the Editor of THE LANCET.

SIR,—In your summary of Dr. Janet Campbell's report to the Ministry of Health on the Teaching of Obstetrics (THE LANCET, April 28th, p. 869) it is stated that St. George's Hospital (amongst others) has no maternity beds. Although this was correct at the time the report was presented, I would point out that this hospital now has a fully equipped maternity ward of ten beds, and I should be glad if you would insert this in your journal so that it may be as widely read as, I have no doubt, was the article in question.

I am, Sir, yours faithfully,

F. J. FRANKAU,

May 4th, 1923.

Deputy Treasurer, St. George's Hospital.

* * We noted that provision of maternity beds was under consideration, and are glad to learn that it was so promptly made.—ED. L.

TUBERCULOSIS OF SACRO-ILIAC JOINT.

To the Editor of THE LANCET.

SIR.—Your correspondent, Mr. P. B. Roth, in his letter to THE LANCET of May 5th points out that my paper on sacro-iliac tuberculosis must have been written prior to the publication of Dr. A. Rollier's "Heliotherapy"; and he questions, first, the rarity of the disease in view of the 83 cases mentioned by Dr. Rollier, and secondly, the necessity for the radical treatment advocated by me. Mr. Roth is quite correct in his surmise: the paper was written early in 1922 and read at the Liverpool Medical Institution in October of the same year. Nevertheless, in spite of the subsequent publication of Dr. Rollier's book and Mr. Roth's gentle criticism, I maintain the statements in my paper, for the following reasons:—

Whitman, quoting the statistics of the Hospital for Ruptured and Crippled during a period of 20 years, gives the following figures for tuberculous disease: spine, 4299; hip, 3329; all other joints, 3222; these figures certainly appear "impressive" when compared with those for sacro-iliac tuberculosis. Later on he says, "Tuberculous disease of the sacro-iliac articulation as compared to disease of the spine or hip-joint is a rare affection and extremely so in childhood." This view is shared by other authors. Dr. Rollier's book not being available at the moment, I am unable to settle the important question as to whether the diagnosis of tuberculosis was verified in all his cases by the finding of the *B. tuberculosis*, especially in those without sinuses.

With regard to Mr. Roth's second point, the necessity for operation, I should like to quote the following extract from your review of Dr. Rollier's book:—

"Routine operative treatment has been entirely abandoned, except for unilateral renal disease and for cases showing large inabsorbable sequestra, while in closed joint lesions practically the only excision that is ever advised is that of the knee-joint in rare adult cases where the disease is very torpid and ankylosis inevitable."

Now in describing the pathology of the disease I pointed out that sequestra are common (the one in my case measured $1\frac{1}{2}$ in. diameter), and that intrapelvic abscess is commoner than extrapelvic, two conditions which appear to call for operation. Finally, it must be admitted that the cold dry air and bright sunshine required for heliotherapy are unfortunately conspicuous by their absence over the greater part of this island, and for the poorer classes at any rate the high Alps are inaccessible.

I am, Sir, yours faithfully,

Liverpool, May 5th, 1923.

H. C. W. NUTTALL.

DYSMENORRHOEA A SYMPTOM.

To the Editor of THE LANCET.

SIR,—Many distinguished gynaecologists from various parts of Great Britain took part in the discussion on dysmenorrhoea introduced by Prof. Blair Bell at the recent meeting of the British Congress of Obstetrics and Gynaecology. If Dr. Lamond Lackie, who presided jointly with Dr. Herbert Spencer, is reported rightly in THE LANCET of April 28th, he referred in summing up to the "enormous diversion of opinion between various speakers. Apparently," he said, "we were disagreed about the frequency of dysmenorrhoea, its causes, and its classification, and its possibility of cure."

This is a very unfortunate state of affairs, and is probably due to trying to make out of a single symptom—namely, pain in association with menstruation—a disease. Prof. Blair Bell quoted Marion Sims, who in 1880, he said, had first insisted that dysmenorrhoea was a symptom and not a disease, a point of view which no one disputed to-day. This appears to have been the only statement practically in which there was unanimity of opinion, as no one present appears to have dissented from it. Indeed, no one could dispute the statement, for it is a fact beyond dispute. Why not, therefore, drop altogether the term dysmenorrhoea, or at least not speak of it as a disease, but merely as a

symptom of many pathological conditions in well-recognised diseases associated with the female genital organs, and certain constitutional states, such as neurasthenia. Only the week previous to the publication of the proceedings of the Congress an article appeared in THE LANCET on the Treatment of Primary or Spasmodic Dysmenorrhoea, by Dr. G. F. Blacker. But Prof. R. J. Johnstone, of Belfast, in his remarks at the Congress said he was very glad that Prof. Blair Bell had made a clean sweep of the old terminology of congestive and spasmodic dysmenorrhoea.

Dysmenorrhoea is a symptom, and should be treated as such, and such only. Dr. J. S. Fairbairn, in his remarks, said he wished to observe that no uterus was made to pattern, and simple variations had not been taken into account. Surely the uterus is made to pattern, and that pattern is what the consensus of recognised opinion has defined as the normal uterus, and the variations from the normal, such as under-development, acute ante-flexion, and the like, are the very conditions which are associated with painful menstruation. The factor of pain in such conditions should be dealt with in text-books of gynaecology under their respective headings, and dysmenorrhoea not given a special chapter as if it constituted a disease in itself. If this plan were adopted it would at once do away with all such terms as intrinsic, extrinsic, congestive, spasmodic, membranous, and ovarian dysmenorrhoea.

I am, Sir, yours faithfully,

Bentinck-street, W., May 1st, 1923.

F. L. PROVIS.

THE TREATMENT OF STAMMERING.

To the Editor of THE LANCET.

SIR,—In the London County Council report of the classes for stammering children, issued under the Public Health Department for 1920, it is stated that 50 per cent. of the cases treated were discharged cured. Dr. E. W. Scripture stated in his paper¹ that not more than 5 per cent. of treated cases ever fully recover. Although the pathology of stammering has never fully been established, I think a lot more might be done to systematise the treatment; there are still many unqualified men treating stammerers, and the percentage of cures is not as large as it should be. It is clear to me, after my experience, that stammering is definitely a neurosis, caused by a congenital tendency, a predisposition, reacted on and made virulent by an external cause—e.g., shock, fear, unfavourable environment. In the X-ray Department at St. Thomas's Hospital it was proved that every stammerer is accompanied with defective movement of the diaphragm, resulting in bad breath control, poor voice, and so on. As in so-called shell shock, the repression of fear leads to defective coördination; faulty speech movement is the result. A feeling of opposition may in certain cases be the cause of stammering, when the environment is unfavourable, but about 60 per cent. of the 500 cases of stammering I had through my clinics in London were caused by the shock of air-raids, the repressed emotion causing defective coördination. Surely stammering can here be classed with other forms of neurosis and treated as such. A stammerer certainly needs treatment, both mental and physical, but cannot the two be amalgamated? Exercises for breath control, relaxation, the cultivation of the melodious voice should be taught in such a way as to give the right suggestion in confidence, self-assertion, and control. No stammerer can be permanently cured by tricks; a stammerer already feels different from his environment, and the treatment should make him feel normal. He has to be given the means of free self-expression by speech the natural and normal method, but as yet I do not feel we have discovered the quickest way of giving that self-expression.—I am, Sir, yours faithfully,

MURIEL H. WIGGLESWORTH,

Late of St. Thomas's Hospital Speech Clinic and the L.C.C. Stammerers' Clinics.

April 27th, 1923.

¹ THE LANCET, April 14th, 1923, p. 749.

UNIVERSITY OF CAMBRIDGE.—A short course for the diploma in Psychological Medicine has been planned to be held in Cambridge from July 10th to August 17th. The subjects covered will be the physiology and anatomy of the nervous system, psychology, psychopathology, mental deficiency, and practical psychiatry. Attendance at separate lectures can be arranged. Applications to attend the course should be sent before June 7th to the secretary, D.P.M. Committee, Psychological Laboratory, Cambridge, from whom further particulars can be obtained. If a sufficient number do not apply the course will not be held.

at Trinity Term 1921. The prize is now of the value of about £100, and is awarded for original research in any subject comprised in the following list: Animal and vegetable morphology, physiology and pathology, and anthropology. Candidates must forward their memoirs to the registrar of the University of Oxford before March 31st. The memoirs may be printed, typewritten or in manuscript; should be inscribed "Rolleston Memorial Essay;" and should bear the name and address of the author. No candidate will be eligible: (1) Who has not either passed the examinations for the B.A. degree or the B.M. degree at Oxford, or for the B.A. degree or the M.B. degree at Cambridge, or been admitted as a candidate for the degree of B.Sc. at Oxford, or as an advanced student for the degree of B.A. at Cambridge; (2) who has exceeded a period of six years from attaining one or other of these qualifications, or from his attaining the first of such qualifications, if he has attained more than one; (3) who has exceeded ten years from his matriculation.

The election to the Senate has resulted in the appointment of the following :—

By His Majesties in Council.—Prof. Sir Arthur Schuster,
F.R.S., and Dr. W. C. Unwin, F.R.S.
By Convocation.—Divinity: The Rev. J. A. Douglas, Arts:
Messrs E. C. Higgins and the Rev. H. B. Workman, Medicine:
Messrs R. A. Young, C.B.E., Science: Mr. C. W. Crook, M.P.,
Dr. C. W. Kannals, and Sir Sydney Russell-Wellis, M.P.
By the Royal College of Physicians of London.—Dr. J. Fawcett,
F.R.S., and Dr. W. C. Unwin, F.R.S.
By the Royal College of Surgeons of England.—Mr. V. Warren
F.R.S., and Dr. W. C. Unwin, F.R.S.

A lecture on the Psychology of Epilepsy will be given at the house of the Royal Society of Medicine, 1, Wimpole street, London, W. 1, by Dr. E. D. Wiersma, Professor of Psychiatry and Neurology in the University of Groningen, on May 24th, at 5.15 P.M. The chair will be taken by Dr. Robert H. Cole. The lecture, which will be delivered in English, is addressed to advanced students of the University and to others interested in the subject. It has been arranged under a scheme for the exchange of lecturers between England and Holland. Admission is free, without ticket.

ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—As the result of the recent Final Examination of the Conjoint Board, held from April 3rd to 26th, the following candidates were approved in the under-mentioned subjects, but are not eligible for diplomas:—

Medicine.—F. J. A. Armonson and W. A. Atkins, Birmingham;
O. D. Ballinger, Oxford and St. Bart.'s; A. A. Battson,
St. Thomas's; R. C. Baxter, Charing Cross; Dora M. Berry,
Royal Free; D. H. Berry, Guy's; E. J. Blackaby, St.
Bart.'s; T. S. Blackledge and E. R. Boland, Guy's; W. B.
Boone and R. T. Brain, London; M. A. B. Brito-
Mutunayagam, St. Thomas's; C. O. S. B. Brooke, St.
Bart.'s; R. Brooke, Guy's; B. H. Burns, St. George's;
Kathleen F. Butterfield, Royal Free; N. E. Chadwick,
St. Bart.'s; W. J. B. Chidlow, Liverpool; J. H. K. Clarke
and L. T. Clarke, Birmingham; Gladys M. Cox, Royal Free;
Cecily D. Crosskey, Birmingham; J. A. Currie, Guy's;
D. D. R. Dale, St. Bart.'s; Nancy B. Daniell, King's Coll.
C. K. David, Univ. Coll.; A. B. Davies, Birmingham;
Gwladys D. Davies, King's Coll.; A. J. Dodhi, Bombay;
G. A. Dolman, King's Coll.; A. F. Doyle, St. Thomas's;
Helen M. Du Buisson, King's Coll.; G. Dudley, Birmingham;
W. H. Dunn, St. Thomas's; P. Ellman, Manchester;
H. N. K. Elphick, King's Coll.; J. L. Faulk, Guy's; A. E.
Ferguson, St. Thomas's; C. W. S. Fernando, Univ. Coll.;
H. L. Fisher, St. Bart.'s; K. Fletcher-Barrett, St. George's;
Mary E. Fox, Royal Free; M. W. M. Gadrat, Paris;
N. G. C. Gane, Middlesex; G. F. Gibberd, Guy's; W. A.
Gornall, Bristol; W. Gough, Birmingham; R. J. Gregory,
St. George's; Elsie C. Griffin, Charing Cross; Rachel
Halperin, Univ. Coll.; Nancy M. Hield and Gladys Hill,
Royal Free; B. O. Hillman, Birmingham; Mary D.
Horton, Birmingham; Phyllis M. Horton and Kathleen M.
Hyslop, Royal Free; C. Ive, Guy's; W. O. C. Jarratt,
St. Thomas's; J. Jones, Univ. Coll.; C. E. Keast, Guy's;
H. N. C. V. G. Kelaart, Ceylon; K. L. E. Kellgren, Royal
Free; M. E. P. Killard-Leavey, Guy's; Charlotte A.
Kingdon, St. Mary's; C. d. W. Kitcat, St. Bart.'s; D.
Kostitch, King's Coll.; K. H. Lachlan, Westminster;
R. E. Lane, Guy's; E. R. P. Madram, Royal Free; C. C.
Mahoney, St. Mary's; P. Marshall and Margaret
D. Mason, London; Gertrude M. Mayhall, Leeds; Ethel
W. Morris, London; A. C. Moyle, St. Thomas's;
L. Mushin and C. A. Nadicarianda, London; M. F. Nicholls,
St. George's; H. M. O'Brien, Birmingham; P. H.
O'Donovan, London; H. L. Oldershaw, St. Bart.'s; Jean
Orr-Ewing, St. Mary's; J. Pearce, Westminster;
Florence M. Pearson, St. Mary's; R. P. Perera, Ceylon and
London; A. C. T. Perkins, King's Coll.; A. T. W. Powell,
Guy's; T. M. Preece, St. Bart.'s; Evelyn R. Pyke, London;
K. Rai, Middlesex; A. J. Reed, London; R. D. Reid,
St. Bart.'s; Laura M. Rhodes, Royal Free and St. Mary's;
W. L. Roberts, Cambridge and Univ. Coll.; St. Mary's,
Middlesex; Annie E. G. Rowlands, Univ. Coll.; T. E.
Ryves, St. Bart.'s; Katharine F. E. Sanders, King's Coll.;
J. N. Sankey, Birmingham; P. N. Seth, London; W. P. H.
Sheldon, King's Coll.; A. E. Sherwell, Bristol; A. J.
Smyth, St. George's; L. V. Snowman, Cambridge and
St. Mary's; Betty Stainer and Muriel A. Stephens, King's
Coll.; M. H. Steyn, St. Thomas's; Edith C. Summerskill,
Charing Cross; H. C. C. Taylor, Guy's; H. A. Thomas,
Liverpool; J. H. Thompson, Univ. Coll.; Doris Todd,
St. Mary's; B. M. Toop, London; N. C. Tughan, Univ.
Coll.; Helen Turover, Charing Cross; Beatrice M. Upshon,
Royal Free; Hygeia L. J. Wallace, Charing Cross; E. H.
Watkins and R. G. R. West, St. Bart.'s; N. L. White,
Univ. Coll.; Doris Williams, Westminster; E. L. Williams,
London; Elsie J. Williams, Royal Free; H. C. M. Williams,
St. Bart.'s; I. E. Wolf, Lausanne; A. W. Wood, Bir-
mingham; Constance A. P. Wood, King's Coll.; J. T.
Wybourn, St. Mary's; Mildred M. E. Yate, Royal Free;
and Joyce P. Yeoman and E. Zimmerli, St. Mary's.

Surgery.—N. F. Adeney, Cambridge and St. Mary's; G. F. Axon, Charing Cross; S. C. Bakhle, Guy's; W. E. Barnie-Adshead, Birmingham; L. G. Blair, London; Hilda A. Bond, Univ. Coll.; W. A. Caldwell, Guy's; E. H. P. Cave, King's Coll.; H. D. Chalke, St. Bart.'s; B. A. Coles, Westminster; A. B. Cooper, St. Bart.'s; V. Cotton-Cornwall, Liverpool; A. B. Davies, Birmingham; P. O. Davies and J. R. B. Dearden, St. Bart.'s; J. S. Dees, Middlesex; D. Diamond, St. Bart.'s; K. S. Dickinson, Durham; G. P. Driver, R. H. Enoch, and G. S. W. Evans, St. Bart.'s; J. L. Farquharson, St. Thomas's; Emily L. Franklin, King's Coll.; G. F. Gibberd, Guy's; G. v. Gollerkeri, Bombay and Middlesex; N. M. Goodman,

London; F. M. Gore, Birmingham; S. A. Grant, London; L. J. Green, Westminster; S. Halperin, St. Thomas's; G. E. R. Hamilton, King's Coll.; M. Hawke, Guy's; B. D. Hendy, London; M. Honigsberger and L. G. Housden, Guy's; C. Iszatt, London; A. H. Johns, St. Bart's; B. H. Jones, St. Thomas's; G. L. S. Kohnstamm, King's Coll.; K. H. Lachlan, Westminster; P. E. M. Lanier, Middlesex; A. L. Lankester, Cambridge and St. Thomas's; T. Latham, Manchester; C. E. M. J. Libert, King's Coll.; B. S. Llewelyn, Westminster; A. R. Macdonald and G. B. McMichael, St. Bart's; C. A. Martin, London; J. Maxwell, St. Bart's; G. A. Metcalfe, St. Thomas's; S. W. H. Moul, Charing Cross; J. R. Nicholson-Lailley, Bristol; E. Obermer, St. Bart's; Carrie H. Osmond, Bristol; J. Parrish, St. Bart's; G. W. V. Parry, Guy's; Louisa O. Paterson, Royal Free; J. N. D. Paulson, St. Mary's; R. T. Payne and J. W. Poole, St. Bart's; Beatrice M. Powell, Royal Free; C. A. Probert, Guy's; W. A. Rankin, Westminster; R. Riley, Cambridge and St. Mary's; Nora A. Robinson, Charing Cross; T. Robson, St. Thomas's; G. F. Rowbotham, Manchester; J. M. Scott, St. Bart's; W. P. H. Sheldon, King's Coll.; J. A. Smorfit, Leeds; A. C. Sommerville, King's Coll.; W. Stephenson, Durham; E. R. S. Sweeney, St. Mary's; P. Thwaites, St. Bart's; H. S. Townsend, King's Coll.; A. Turner, St. Mary's; S. Vatcher, Cambridge and London; Marian E. Williams, Royal Free; R. K. Wilson, Cornum, Guy's; R. E. Wilson, London; and E. Wornum, Guy's.

Midwifery.—B. Abelman, Liverpool; Iris I. G. Adams, St. Mary's; J. C. Ainsworth-Davis, St. Bart's; J. N. Alexander, Guy's; L. V. Angel, Liverpool; E. N. C. Annis, Guy's; F. H. Armanious, St. Thomas's; C. F. Ashby, Guy's; and I. Atkin, St. Bart's; W. A. Atkins, Birmingham; P. E. Bardsley, St. Thomas's; St. C. E. J. Barrett, Middlesex; R. C. Baxter, Charing Cross; J. S. Benzecry, Univ. Coll.; D. H. Berry, Guy's; H. M. Bird, Middlesex; T. S. Blackledge, Guy's; A. J. Boyd, St. Thomas's; Gwendolen J. Brooke, Univ. Coll.; Edna V. Butler, Bristol; W. A. Caldwell, Guy's; Eileen A. Chennell, St. Mary's; W. J. B. Chidlow, Liverpool; J. H. K. Clarke, and L. T. Clarke, Birmingham; N. B. Cooke, Liverpool; R. Cove-Smith, King's Coll.; R. S. Creed, St. Thomas's; Cecily D. Crosskey, Birmingham; S. S. Cruden, St. Bart's; S. H. Currie, London; C. H. C. Dalton, St. Bart's; Agnes S. Daniel, St. Mary's; A. B. Davies, Guy's; G. I. Davies, Univ. Coll.; A. M. Deane, St. Thomas's; F. M. Deighton, Univ. Coll.; T. D. Deighton, St. Bart's; J. A. F. Denysen, Guy's; Miriam Phoebe de Villiers, Royal Free; J. C. G. Dickinson, Guy's; K. S. Dickinson, Durham; A. S. M. Douglas, Guy's; E. F. Duck and Doris L. Durie, Univ. Coll.; H. E. K. Eccles, St. Bart's; Barbara J. Edwards, Birmingham; C. L. Elgood and J. Elgood, St. Bart's; Josephine O. Ellen, Charing Cross; H. N. K. Elphick, King's Coll.; M. Emery, Basle; W. M. Evans, Univ. Coll.; S. W. Eveson, London; Mary E. Fox, Royal Free and St. Mary's; T. F. Fox, London; Dorothy E. Galbraith, Royal Free; A. Gelberg, Middlesex; W. T. M. Gentle, St. Mary's; W. H. George, London; G. V. Gollerkeri, Bombay; A. W. Gott, Leeds; C. W. Greenway, Guy's; R. J. Gregory, St. George's; W. E. Grice, Middlesex; C. J. P. Grosvenor, St. Bart's; J. A. E. M. Hadley and L. W. Hale, Univ. Coll.; C. C. Halliwell, St. Thomas's; G. E. R. Hamilton, King's Coll.; R. C. Hatcher, Bristol; M. Hawke, Guy's; Nancy M. Hield and Gladys Hill, Royal Free; B. O. Hillman, Birmingham; May D. Horton, Birmingham; Katherine E. W. Hulse, Charing Cross; Kathleen M. Hyslop, Royal Free; C. Ive, Guy's; C. M. Jennings, St. Bart's; I. S. Jones, Liverpool; J. Jones, D. J. Jones, St. Thomas's; N. A. Jory, St. Bart's; C. E. Keast, Guy's; H. C. N. v. G. Kelaart, Ceylon; R. A. E. Klaber, St. Bart's; E. H. Koerner and R. E. Lane, Guy's; O. B. Lean, Univ. Coll.; W. R. A. Line, Birmingham; W. A. Lister, London; D. T. Lloyd, St. Bart's; R. J. Lythgoe, Univ. Coll.; J. A. Macfadyen, St. Bart's; R. R. Macintosh, Guy's; R. S. MacLachlan, Middlesex; L. P. Marshall, St. Thomas's; H. J. Mann, St. Mary's; T. F. London; Lucy M. T. Masterman, St. Mary's; T. F. Meyrick and H. D. N. Miller, King's Coll.; Elspeth B. Moffat, Royal Free; C. A. Moody, St. Bart's; G. O. Morgan, King's Coll.; H. S. Morley, Univ. Coll.; G. O. Morris, Guy's; Una Frances M. Morton, Univ. Coll.; L. N. Moss, St. Mary's; A. C. Mowle, St. Thomas's; Jeannette F. L. Murray, St. Mary's; C. Myers, Sheffield; M. Myers, Durham and Guy's; Josephine W. Nagel, Royal Free; E. E. Neser, Guy's; J. W. Newbold, Univ. Coll.; F. N. Newell-Roberts, Guy's; C. E. Newman, King's Coll.; Frances L. Nichol, Royal Free; J. R. Nicholson-Lailley, Bristol; H. M. O'Brien, Birmingham; T. J. O'Donnell, London; T. B. Pahlajani, Charing Cross; R. T. Payne, St. Bart's; Edith G. Peacock, Charing Cross; G. G. Penman, St. Thomas's; Annie Pichalmuthu, Madras; J. W. Poole, St. Bart's; Evelyn R. Pyke, London; K. Rai, Middlesex; Violet R. H. Rains, King's Coll.; Laura M. Rhodes, St. Mary's; L. E. Robinson, Univ. Coll.; T. Robson, St. Thomas's; M. Rockfelt, Univ. Coll.; E. J. H. Roth and T. E. Ryves, St. Bart's; J. N. Sankey, Birmingham; R. W. Savage, St. Bart's; Margaret B. Savory, Univ. Coll.; R. W. Scarff, Middlesex; J. M. Scott, St. Bart's; H. Seelenfreund and T. A. Shaw, Guy's; N. Smith, St. Bart's; N. R. Smith, St. Thomas's; R. W. Smith, St. George's; L. V. Snowman, St. Mary's; K. H. Southall, Univ. Coll.; R. H. Stanbridge, London; E. G. Steeler, St. George's; G. G. Stewart, St. Bart's; J. D. M. Stewart, Cambridge and St. Bart's; R. V. Storer, Adelaide; F. O. T. Strange, King's Coll.; Viva E. K. Stuart, St. Mary's; Margaret Swete, Royal Free; H. C. C. Taylor, Guy's; H. A. Thomas, Liverpool; G. L. Thompson, Cambridge and London; J. H. G. Thompson, St. Thomas's; G. K.

Thornton, St. George's; H. F. Turney, St. Thomas's; G. C. Vaughan, Birmingham; A. L. Walker, Middlesex; S. A. Walker, Liverpool; L. J. Watkins and E. R. Weaver, Adams, St. Thomas's; B. M. R. West, Middlesex; H. A. M. Whitby, St. Bart's; R. W. White, London; T. M. Wilks, King's Coll.; Elsie J. Williams, Royal Free; Cicely F. Wilson, Bristol; T. J. Wilson, St. Bart's; Esther Wingate, Royal Free; I. E. Wolf, Lausanne; Edith V. Wood, T. E. W. R. Wood, and B. H. H. Wooderson, London; E. Wornum and S. C. H. Worseldine, Guy's; J. T. Wybourn, St. Mary's; H. D. Wyse, Guy's; and Joyce P. Yeoman and E. Zimmerli, St. Mary's.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held recently the following candidates passed in the subjects indicated:—

Surgery.—R. Caplan, Glasgow; and L. A. Daly, St. Bart's Hosp.

Medicine.—W. E. Farnham, Birmingham; B. Hart, Sheffield; L. D. A. Hussey, King's Coll. Hosp.; and W. J. Jameson, Albany Med. Coll., New York.

Forensic Medicine.—B. Hart, Sheffield; L. D. A. Hussey, King's Coll. Hosp.; W. J. Jameson, Albany Med. Coll., New York; I. Lipman, Westminster Hosp.; and S. Thompson, Leeds.

Midwifery.—C. M. John, Madras and Royal Free Hosp.; I. Lipman, Westminster Hosp.; M. McW. Lopez, Univ. Coll. Hosp. and Bristol; H. MacLachlan, Guy's Hosp.; O. Sinanides, Athens; S. Thompson, Leeds; and R. A. Walker, St. Thomas's Hosp.

The Diploma of the Society was granted to the following candidates entitling them to practise medicine, surgery, and midwifery: L. A. Daly, L. D. A. Hussey, M. McW. Lopez, and R. A. Walker.

THE Mackenzie-Davidson Memorial Lecture will be delivered by Prof. A. W. George, of Boston, Mass., on Thursday, May 17th, at 5.30 P.M., in the Barnes Hall of the Royal Society of Medicine. Dr. George will take as his subject the Pathological Gall-Bladder.

MEDICO-LEGAL SOCIETY.—A meeting will be held on May 15th, at 8.30 P.M., at 11, Chandos-street, Cavendish-square, London, W. 1. A paper will be read by Mr. A. H. Trevor on the Mental Treatment Bill, 1923, and will be followed by a discussion.

SOCIETY FOR CONSTRUCTIVE BIRTH CONTROL AND RACIAL PROGRESS.—A meeting will be held on May 16th, at 8 P.M., at Essex Hall, Strand, London, W.C. Earl Russell will give a lecture on Progress and the Law, to be followed by a discussion.

GLASGOW UNIVERSITY CLUB, LONDON.—The summer dinner will be held at the Trocadero Restaurant, London, W., on Friday, June 1st, at 7.30 P.M., when the Lord Rector, Lord Birkenhead, will preside. Any Glasgow University men who, though not members of the club, would like to attend are invited to communicate, as soon as possible, with the hon. secretaries, 1, Harley-place, N.W. 1.

ABERDEEN UNIVERSITY CLUB, LONDON.—The sixty-ninth half-yearly dinner will be held at Gatti's Restaurant, London, W.C., on May 17th at 7.30 P.M., Prof. J. Arthur Thomson in the chair. Past or present graduates of either sex desiring to be present are asked to communicate with the Secretary, Dr. W. A. Milligan, 11, Upper Brook-street, London, W. 1.

MEDICO-PSYCHOLOGICAL ASSOCIATION.—The next quarterly meeting of the Medico-Psychological Association of Great Britain and Ireland will take place on May 24th at 11, Chandos-street, Cavendish-square, London, W., under the presidency of Prof. G. M. Robertson. Dr. C. K. Clarke, of Toronto, will deliver the Fourth Maudsley Lecture at 3 P.M. at the house of the Royal Society of Medicine, 1, Wimpole-street, London, W. It is proposed to hold a dinner at the Langham Hotel, Portland-place, London, W., on the evening of May 24th, in honour of Dr. Clarke. Members are asked to write to the General Secretary, Dr. R. Worth, Springfield Mental Hospital, London, S.W. 17, stating the number of tickets they require. The annual meeting will take place in London between July 9th and 13th.

The Gaskell Prize and Medal (value £30) was founded in 1887, to honour the memory of the late Mr. Samuel Gaskell, F.R.C.S., at one time medical superintendent of the Lancaster County Lunatic Asylum, Lancaster, and subsequently for 17 years a Commissioner in Lunacy. The prize is given annually to that assistant medical officer who shall most distinguish himself in an examination held in July. Candidates must produce evidence: (a) Of having attained the age of 23; (b) of having been qualified medical officers in one or more asylums for at least two years; (c) of possessing the certificate in Psychological Medicine of the Medico-Psychological Association of Great Britain and Ireland. Candidates will be examined in: psychology; healthy and morbid histology of the brain and spinal cord; the diagnosis, prognosis, pathology, treatment, and legal relations of mental disorders; clinical cases with commentaries. Fourteen days notice to the registrar is required.

MIDDLESEX HOSPITAL MEDICAL SCHOOL.—An Emeritus lecture will be delivered by Sir John Bland-Sutton, F.R.C.S., on June 5th, at 3 P.M., in the Medical School, on the Choroid Plexuses and Ventricles of the Brain as a Secreting Organ.

MANCHESTER DENTAL HOSPITAL.—At the annual meeting it was stated that during the year the attendances of patients increased by 6000, or roughly 20 per cent. The amount contributed by the public in subscriptions was only £220, against an expenditure of £2700. The loss on the year's work amounted to £1000, and the committee are now faced with a deficit on revenue and building fund approaching £6000.

WHOOPIING-COUGH IN MANCHESTER.—Whooping-cough and measles appear to be slightly on the increase in Manchester. In the week ending Saturday, April 28th, the new cases of whooping-cough numbered 123 and the deaths 10; new cases of measles, 128, with 3 deaths. Pneumonia also was slightly on the increase—89 new cases and 45 deaths.

FEDERATION OF MEDICAL AND ALLIED SERVICES.—The annual dinner of the Federation has been postponed from May 23rd to Tuesday, May 29th, to suit the convenience of the Rt. Hon. N. Chamberlain, M.P., Minister of Health, who will be the chief guest, and that of several prominent Members who will be away during the Whitsun Parliamentary recess. The dinner will take place at 7.15 P.M. at the Langham Hotel, when it is hoped that members will make every endeavour to support the chairman, Sir Berkeley Moynihan, by their presence and take the opportunity of meeting those actively engaged in the work. The price of tickets is 12s. 6d., exclusive of wine, and communications should be made to Lieut.-Colonel N. Howard Mummery, medical director.

BIRMINGHAM AND MIDLAND SKIN AND URINARY HOSPITAL.—The annual report for 1922 contains a statement by the Medical Committee indicating the value of Erlangen deep-therapy for the treatment of cancer and other forms of malignancy. Illustrative cases are given. Among non-malignant conditions which have reacted favourably are fibroid tumour of the uterus, Hodgkin's disease, and keloid, while in lupus the treatment does not seem to have yielded better results than those obtained by ordinary X ray treatment. In the in-patient department 377 patients stayed an average of 19 days each, and one death occurred during the year; in 1921 the number of cases was 212, and the average stay 32 days. 6933 cases were seen in the out-patient department, as compared with 7719 in 1921. The total ordinary income was £7822 and the expenditure £8903.

THE LATE DR. ATLEE HUNT.—The death is announced on May 6th of Dr. Edgar Atlee Hunt. He was in his seventieth year and was living in Colchester where he had been in practice for a great number of years, remaining on his retirement from practice consulting surgeon to the Essex and Colchester Hospital and to the Royal Eastern Counties Asylum, a branch of his work in which he took particular interest. Dr. Hunt, who was educated at Uppingham and St. George's Hospital, was an excellent example of the competent and all-round general practitioner who keeps himself abreast alike of scientific work and social developments. Before starting practice in Colchester he had been resident obstetrician at St. George's Hospital. In his youth he was a prominent football player and could have had his cap for England, but circumstances prevented acceptance of the offer.

LONDON TEMPERANCE HOSPITAL.¹—The fiftieth annual report of this hospital, which was presented on March 28th, describes the year 1922 as one of unusual difficulty and anxiety. Nevertheless much-needed improvements have been effected in the post-mortem and out-patient departments, more than £2000 having been outlaid thereon, along with the cost of painting and cleaning. A Dean's diaspore has been fitted up in the X ray department and new equipment provided in the massage department. Happily the cost of provisions has been falling, while payments from patients have materially increased. The number of in-patients treated during the year amounted to 1059, against 1425 for 1921, the decrease being accounted for by two months' closure of the in-patient department in the summer, which had also the effect of raising the average total cost per in-patient to £14 7s. 1d. from £11 7s. 9d. in 1921. The deficit was reduced from nearly £8000 to £728 in the course of the year, chiefly owing to a large legacy. The building of the new nurses' home was put in hand, and an extensive building scheme, to include a new secretary's department, kitchen, and operation department still needs a sum of £20,000 before it can be completed free of debt. The Band of Hope Union is co-operating this year in a novel scheme for collecting money.

¹ We regret that a report which appeared under this heading last week referred to another hospital.

MEDICAL SOCIETY OF LONDON: ANNIVERSARY DINNER.—The 150th anniversary dinner of the Medical Society of London will be held at the Hyde Park Hotel (entrance through the Grill Room) on Tuesday, May 15th, when H.R.H. the Prince of Wales will be the principal guest. The toast of "Medicine and the Medical Society of London" will be proposed by the Right Hon. David Lloyd George and responded to by Lord Dawson, the President. The toast of the "Sister Professions and the Guests" will be proposed by Sir John Bland-Sutton, and responded to by the Lord Chief Justice, Lord Hewart, and by the Right Hon. Neville Chamberlain, Minister of Health. The President will receive the Fellows and their guests at 7.30 P.M. They are requested to take their places at the dinner tables at 7.45 P.M. in order that the audience may be seated before the arrival of the Prince. It is suggested that the interval might be utilised in ordering such wines as are wished for. Amongst the guests will be: Lord Justice Atkin, Viscount Astor, Sir Clifford Allbutt, Prof. Angus, Sir Anthony Bowlby, Dr. Hubert Bond, Lord Burnham, the Bishop of Birmingham, Prof. Blair Bell, Mr. A. H. Burgess, Dr. Arnold Chaplin, Sir E. Cooper Perry, the Earl of Donoughmore, Sir Crisp English, Mr. Elliott (Lettsom family), Sir Walter Fletcher, Dr. Fothergill (Fothergill family), Sir John Goodwin, Prof. E. W. Hey Groves, Prof. A. W. George (Boston), Sir Archibald Garrod, Sir William Hamer, Sir William Hale-White, Mr. Patrick Hastings, K.C., Sir Edward Marshall Hall, K.C., Sir Robert Hadfield, Prof. F. Gowland Hopkins, Sir Robert Jones, Dr. Robert Knox, Lord Kenyon, Sir William Lister, Sir William Leishman, Sir John Lynn-Thomas, Dr. F. N. Kay Menzies, Sir William Macewen, Prof. R. Muir, Prof. J. Marnock, Sir George Newman, Sir William Orpen, Sir Arthur Pinero, Hon. Sir Charles Parsons, Sir Milsom Rees, Prof. G. M. Robertson, Sir Arthur Robinson, Lord Riddell, Sir Squire Sprigge, Sir Arthur Stanley, Sir Harold Stiles, Prof. W. S. Thayer (Johns Hopkins), Mr. H. J. Waring, Sir Aston Webb, Sir W. de C. Wheeler, and Sir Alfred Yarrow.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—A deputation from the College, consisting of Sir William I. de C. Wheeler, president; Mr. R. C. B. Maunsell, vice-president; Sir Lambert Ormsby, secretary; Sir Thomas Myles, Sir Arthur Chance, Sir Conway Dwyer, and Mr. Alfred Miller, registrar, waited on the Governor-General of the Free State last week for the purpose of presenting an address of welcome. The address included an assurance that the services of the College would on all occasions be placed loyally and wholeheartedly at the disposal of the Government of the Irish Free State wherever questions arose affecting the public health or the welfare of the people. The Governor-General, in his reply, dwelt on the esteem in which Irish surgeons were held for skill, originality, and courage. The members of the deputation afterwards had luncheon with the Governor-General.

PARIS POST-GRADUATE LECTURES.—*Hôpital Trousseau.*—Ten lectures on Clinical Treatment of Non-Tuberculous Affections of the Bones in Children will be given by Dr. Hallopeau, surgeon to the hospital, from July 2nd to 13th. The treatments discussed will be those of fractures of arm, fractures of leg, acute osteomyelitis, congenital club-foot, scoliosis, acquired deformities (flat-foot, hallux valgus, torticollis, &c.), sequelæ of infantile paralysis, flail joints and pseudoarthrosis, ankylosis, and congenital luxation. Full particulars on application to the hospital, Rue Michel Bizot, Paris.—*Hôpital Maritime de Berck:* The above course will be followed by a course of 12 lectures on Tuberculosis of the Bones, Joints, and Glands, and the Elements of Practical Orthopaedics, by Drs. Sorrel, Andrieu, Tridon, Mozer, and Parin, from July 16th to 29th. The mornings will be devoted to practical demonstrations, and lectures will be held in the afternoons. The subjects will be Pott's disease; coxalgia; tuberculosis of the knee-joint; tuberculous osteitis and osteo-arthritis of the foot; tuberculous of the shoulder, elbow, and wrist; spina ventosa and cold abscess of soft parts; laboratory and radiographic diagnosis: non-tuberculous osteitis and osteo-arthritis; chronic adenitis; rachitism and scoliosis; congenital luxation of the hip. Full particulars on application to Dr. Parin, at the hospital, Berck-Plage.

NORTH WALSHAM MEMORIAL HOSPITAL.—In January, 1919, it was decided that the war memorial of the town should take the form of a cottage hospital, and the foundation-stone was actually laid in the latter part of that year. On April 23rd last a public meeting was held to receive the report of the committee which was presented by Dr. C. H. W. Page, who stated that the plans and architect for the proposed hospital had been approved, and the committee were of opinion that they were now financially justified in building. The total available resources were £7108, £380 of which represented the value of land, apparatus, and

furniture, leaving a balance of £6728. Approximately £100 per annum in annual subscriptions had been promised. The architect had stated that the estimated cost of erecting the building, including everything except actual furniture and architect's fees, was £3500. The hospital was planned to contain three male and three female beds, two private rooms containing one bed each, an operating room, and the necessary administrative offices. Dr. Page stated that a bed in the Norfolk and Norwich Hospital cost £160 per annum, whereas it was estimated that a bed in the proposed cottage hospital would only cost about £79. Last year there were 60 cases sent from North Walsham to the Norfolk and Norwich Hospital. Most of them could have been dealt with in a cottage hospital, and it was well known that there was a great shortage of beds in the Norfolk and Norwich Hospital. Sir Hamilton Ballance, one of the surgeons to that institution, had expressed himself as favourable to the scheme. The Secretary of the North Walsham Branch Saturday and Sunday Fund said that they now had 700 members and that the proposed local hospital would receive considerable help from the fund. All local workmen were in favour of the proposed hospital. It was decided that the work should be proceeded with.

ROYAL INSTITUTION.—At a general monthly meeting held on May 7th Sir J. J. Thomson was elected honorary professor of natural philosophy and Sir Ernest Rutherford professor of natural philosophy. It was announced that the following, among others, had been nominated as Vice-Presidents for the ensuing year: Dr. Mitchell Bruce, Sir James Crichton-Browne (treasurer), and Sir Arthur Keith (secretary).

In connexion with the first annual joint meeting of the Röntgen Society and the Electro-Therapeutic Section of the Royal Society of Medicine, a dinner will be held at the Langham Hotel on Thursday, May 17th, at 8 P.M. (price 10s. 6d., exclusive of wine, payable at the table). Members who wish to be present are asked to notify the secretary of the Electro-Therapeutic Section of the R.S.M., 1, Wimpole-street, London, W. 1.

THE LATE MR. CHARLES KILLICK.—The medical profession, not only of Bradford but also of a much wider area, has to deplore the sudden and tragic death on April 27th, at the age of 48, of Mr. Charles Killick, M.D. Camb., F.R.C.S. Eng., hon. ophthalmic surgeon to Bradford Royal Infirmary. Apparently in normal health, he infected his finger while examining an ophthalmic patient, and died of septicæmia within nine days. Born near Bradford, a member of a well-known professional family, he received his medical education at Cambridge University, and after graduating with honours in the Natural Science Tripos, he gained a University Scholarship at St. Mary's Hospital, Paddington. His bent, ophthalmological almost from the first, soon led him to take up that branch of surgery, and he spent many years in Maidstone in ophthalmic practice and as hon. surgeon to the Kent County Ophthalmic Hospital. In spite of his success there, he felt that Kent was not sufficiently bracing for his children and he returned to Bradford, becoming hon. ophthalmic surgeon to the Royal Eye and Ear Hospital. He was a life member of the Soc. Opht. de France, a member of the Council of the Ophthalmic Section of the Royal Society of Medicine, and a frequent contributor to the literature of his subject. His chief hobby was the translation of French and other foreign ophthalmic works, and he greatly preferred literary and scientific studies to outdoor recreation. Of recent years he became interested in Freemasonry, and obtained in a very short time an astonishing mastery of its ritual. His geniality and mental alertness as well as his great medical abilities made him universally popular in Bradford, where his early death is felt as a severe loss to the profession. Sympathy is extended to his widow and young children.

HOUSE OF LORDS.

THURSDAY, MAY 3RD.

MENTAL TREATMENT BILL.

The EARL OF ONSLOW, in moving the second reading of the Mental Treatment Bill, said that public attention had recently been drawn to the question of the lunacy law and administration, and early last year a conference, consisting of the chairmen of the visiting committees, medical superintendents of mental hospitals, and a number of specialists, was arranged by the Board of Control. The conference decided to ask the Government to obtain legislation permitting treatment without certification in institutions approved by the Board of Control. At present the lunacy laws dealt, firstly, with the detention of lunatics, so as to prevent them from injuring themselves or other people; secondly, they were devised to secure humane and proper treatment of lunatics in mental hospitals; and thirdly, to secure their property against fraud or misappropriation. They did not deal exhaustively with cure, the importance of which was realised when it was known that they had now some 120,000 certified lunatics in 172 institutions costing £8,000,000 a year. To these were added 22,000 fresh cases every year, of whom about 32 per cent. were discharged as recovered. In addition, there were 150,000 persons who were feeble-minded and also a percentage of the population (some people said as high as 10 per cent.) who were dull and backward mentally. Lastly, they had the cases of neurasthenia and psycho-neurosis. All this was a serious drain upon the capacity of the nation, and modern science told them that much of it was preventable by careful watching and early treatment. A distinguished alienist told him the other day that his practice was scarcely at all with certified patients; it was mainly with young people in whom signs or suspected signs of mental disorder were detected. As the law stood at present it was not possible or, at least, very difficult to provide for the treatment of incipient mental disease without certification, against which there was very naturally and very properly a strong feeling. The chief purpose of the Bill was to provide that a patient suffering from incipient mental disorder might be received for treatment without certification. This system had been adopted for many years in Scotland, while in this country, under the Act of 1890, voluntary boarders had been allowed in private licensed houses. Everyone recognised how enormously important it was that no power should be given and no loophole opened for the improper use of provisions such as those contained in the Bill. Among the safeguards which they had introduced, first of all the institution must be one which was approved by the Board of Control and under frequent inspection by them. Secondly, there must be a recommendation from two doctors. And thirdly, no patient could be admitted unless it was at his own voluntary request.

Persons Incapable of Volition.

But many cases of incipient mental disease were incapable of volition, and such cases very often, if treated properly, were capable of complete cure. In such cases as these before they could be admitted the recommendation of the two doctors had to be countersigned by a justice of the peace or a minister of religion personally acquainted with the patient, but not related to him, and the person signing the document must have seen the patient and satisfied himself that he was incapable of volition or voluntary action at the time. A similar procedure was required in the case of minors and, of course, in addition the consent of the parent or guardian must be obtained for the admission of a minor into one of these institutions. One of the doctors, at least, must be a medical man approved by the Board of Control.

The patient could come into the institution at first for a maximum period of six months, which might be extended for another maximum period of six months, being one year in all. He could not undergo this treatment for more than a year. If he was not cured after the year was over, the ordinary provisions of the existing Acts would apply, but at any time during the year he might leave the institution by giving 48 hours' notice, or he might be discharged by the superintendent, or by order of the Board of Control. It was provided in Clause 1 (3) for county and borough councils acting through their visiting committees, to receive patients into their own institutions. In Clause 4 it was also provided that visiting committees should be able to arrange for general hospitals to receive patients of this kind and to work in conjunction with visiting committees. If this could be done great advantage to patients might ensue by getting them away from contact with certified cases, and it would enable all the resources of medicine, other than those provided especially for mental disease, to be at the disposal of the patient. The patient, of course, could also be received in registered hospitals, which were mostly charitable foundations.

or licensed houses which were otherwise known as private asylums.

Out-patient Treatment and After-care.

Another provision of the Bill enabled visiting committees to provide out-patient treatment for persons suffering from mental disorder. They would be at liberty to do this either in institutions under their own control or by arranging for it to be done in general hospitals in the same way as they would be empowered to arrange for in-patients. An outdoor clinic for nervous and mental cases had been established at the Radcliffe Hospital, Oxford, with the greatest possible success. No difference was made between nervous and mental patients. It had been found that patients and their friends were much more ready to come to a clinic of this kind than to a separate mental hospital, and altogether the results had been justified.

The Bill also provided that visiting committees might make provision for the after-care of patients. It had been found that many patients who were discharged as cured were apt to break down again unless they were carefully and kindly looked after during the months following their discharge. This question of after-care, therefore, was of the utmost importance if they wished to make permanent the cures effected in mental hospitals; and it was to be hoped that the visiting committee would give their most careful attention to the provision of this service.

Unknown Causes of Mental Disease.

In spite of the progress in knowledge of mental disease during the last quarter of a century, it was still an unfortunate fact that many of the causes of mental illness were largely unknown at present. If mental disease could be systematically explored they might assume that much progress might be made in the prevention and cure of this disease. In Clause 2, Subsection (5), provision was made for more systematic research and more opportunity was given for the expenditure of public money upon that research. Co-ordination—a most important point—was provided for by requiring that the researches should be undertaken with the approval of the Board of Control. In this measure they endeavoured to extend the functions of the visiting committees to enable them to carry out their present duty more efficiently and also to cope with the new duties which would be placed upon them by this Bill. Firstly, they provided that a proportion, not exceeding one-third, might be persons who were not members of the Council. This was a principle which had been adopted in regard to education committees, maternity and child welfare committees, and so forth, and it was designed to enable the Committee to co-opt expert opinion among their members, and also to get the services of people who might not be members of the Council, but who were willing to give their whole time or a large part of their time to the work of the Committee. Two at least of each visiting committee would be women, and the committees were given power to carry out their duties jointly with other authorities. The expenses of visiting committees were to be defrayed by the local authorities within the county or borough within whose area they operated. The maintenance of cases which came in for treatment for incipient disease had no connexion with the Poor-law. There was no pauper rate. The local authority could either treat them or might make arrangements for their maintenance, the cost falling upon the general fund and not on the guardians of the union in which the patient happened to reside.

The Question of Inspection.

The Mental Deficiency Act of 1913 greatly increased the amount of visiting and raised the number of Commissioners to 11. At present there were seven Commissioners, one a woman who, being neither a lawyer nor a doctor, could not pay statutory visits. The existing staff could not cope with the growing work and, of course, this Bill would probably throw extra inspection upon the Board. It was quite out of the question to reduce the number of statutory visits, but a great many of these statutory visits and local work which now had to be done by Commissioners could, in the view of the Ministry of Health, be efficiently done by inspectors if the law allowed, and the most economical and practical method would seem to be to limit the number of Commissioners to eight and allow the visits and local work to be carried out by inspectors instead of Commissioners, where this can properly be done. This was provided for in Clause 3, Subsection (2). That, in the view of the Ministry of Health, was the best method for providing for the proper inspection which would be required under this Act.

The Bill Discussed.

LORD BUCKMASTER welcomed the Bill, but said he thought that under proper safeguards greater power should be given by the measure for the treatment of these patients. To his mind it was an appalling fact that the reproduction of our population was taking place in inverse ratio to the value of the people who were being produced. He thought the time had come when the whole question of the perpetuation of an utterly unfit, weak-minded, and insane should be the

subject of full investigation, and he wished the Government had had the courage before they introduced the Bill to appoint a Commission to consider the whole question.

THE BISHOP OF WORCESTER said that the present fear of being sent to an asylum would disappear when people realised that these hospitals were places of cure. The medical staff of these institutions were doing a great work, and they had done nothing like what they ought to do to protect those who were giving their lives to the State in this work. Whatever the defects of detail of the measure, their lordships would thankfully accept it as a rather wonderful instalment of fresh hope for those who had been suffering in these sad ways.

EARL RUSSELL congratulated the Government on the introduction of the measure. Practically everyone, he said, who had studied the question would favour the sterilisation of the insane in view of the hereditary and fairly prolific character of these cases. He urged that the 48 hours' provision in Clause 5 should be extended by making a patient's discharge subject to an order of the Board of Control.

THE EARL OF ONSLOW said that the introduction of compulsion in retaining a patient in an institution longer than 48 hours would be a considerable step beyond what was proposed in the Bill, and he could not give any indication that the Government would adopt it if it came up for consideration in Committee.

The Bill was read a second time.

HOUSE OF COMMONS.

WEDNESDAY, MAY 2ND.

Naval and Military Hospitals at Hong-Kong.

MR. GERSHOM STEWART asked the First Lord of the Admiralty whether it would be possible to effect an economy in naval expenditure at Hong-Kong by amalgamating the naval and military hospitals, and, in view of the fact that the naval hospital was very near to the reclamation being carried out in the harbour and of the very high price of land ruling in the colony, if he would consider the advisability of disposing of the site of the present naval hospital, for which a large sum of money could be obtained.—MR. AMERY replied: This question was carefully considered by the Board of Admiralty 12 months ago, and later came under the review of the committee appointed by the late Government to consider the amalgamation of services common to the Navy, Army, and Air Force. The conclusion arrived at was that there would not be a sufficient margin of accommodation if amalgamation were to take place. This would especially be the case as regards officers, the military hospital at Hong-Kong having only six equipped beds for officers.

Village Settlements for Tuberculous ex-Service Men.

COLONEL SIR ARTHUR HOLBROOK asked the Minister of Health whether he would take some action in furtherance of village settlement schemes for tuberculous ex-Service men, as recommended by the Barlow Report of 1918, by the establishment of additional settlements; and whether it was now contemplated to complete the village settlements at Papworth Hall, Cambridgeshire, and Barrowmore, in Cheshire.—MR. NEVILLE CHAMBERLAIN replied: I have recently discussed this question with representatives of the British Legion at a meeting at which my right hon. friend the Minister of Pensions was also present. I am endeavouring to arrange for a personal visit to the settlement at Papworth and also to that at Preston Hall, Kent, during the Whitsun recess, and I hope to be able to arrive at a final decision on the whole question very soon afterwards.

Overcrowding in Poplar.

MR. LANSBURY asked the Minister of Health whether he had received a communication from the medical officer of health for the Borough of Poplar enclosing a statement of 10 typical cases of serious overcrowding in the borough and specially drawing attention to the fact that in every case a person suffering from tuberculosis was living and sleeping with the men, women, and children existing under these conditions; whether he was aware that the medical officer of health for Poplar, on the instructions of the health committee, had on many occasions made representations to Ministers of Health urging that the law should be put into operation for clearing the slum areas in the borough, and that the official reply of the Ministry had always been that the local and national finances did not permit of these unhealthy areas being dealt with; and would he give instructions to one of the officers of his department to proceed to Poplar and advise the medical officer of health and the borough council what steps they should take in order to efficiently deal with the prevailing conditions, which daily became more deplorable.—MR. NEVILLE CHAMBERLAIN replied: The answer to the first question is in the affirmative. The answer to the second question is that I am not, as at present advised, aware of official correspondence between the Ministry of Health and the medical officer of health of the character

mentioned or of such official statements as are mentioned. The answer to the third is that the nature of the action which can be taken in such regrettable conditions, short of rehousing the people, should be within the knowledge of the medical officer of health. As regards rehousing, I may add that it is for the Borough Council of Poplar to approach the L.C.C. with a view to proper consideration of the claim of the borough for inclusion in the general scheme of slum improvement in London which is under consideration and for which State assistance would be forthcoming under the Housing Bill.

Milk and Dairies (Amendment) Act.

Mr. HANNON asked the Minister of Health whether he was aware that the uncertainty as to the date on which the regulations under the Milk and Dairies (Amendment) Act will come into operation was causing perturbation amongst those interested in the improvement of the conditions of the national milk-supply, and that the majority of dairymen were postponing action until such time as the intentions of the Ministry of Health were known; and whether he intended to fix July 1st, 1923, as the date on which the regulations would come into force.—Mr. NEVILLE CHAMBERLAIN replied: I assume that my hon. friend is referring to the Milk (Special Designations) Order, 1922, which came into operation on Jan. 1st last. In accordance with the promise which I gave on March 13th to my hon. friend the Member for the Stone Division, the Order has been revised in certain matters of detail and I hope to be in a position to issue the revised Order at an early date. It is proposed that the new Order shall come into operation on July 1st next.

Approved Societies' Funds and Medical Benefit.

Sir KINGSLEY WOOD asked the Minister of Health whether the Government actuary notified Sir Eric Geddes's Committee that he could not safely advise that the funds of approved societies could bear any further burden in respect of increased payments on account of medical benefit without an increase of contributions; and whether he had given any further advice on this subject.—Mr. NEVILLE CHAMBERLAIN replied: The advice given by the Government actuary to the Committee on National Expenditure in regard to the matter referred to by the hon. Member is contained in Appendix B. to the first report of that committee (Cmd. 1581), page 139. The Government actuary gave further advice on the subject in his report on the Financial Provisions of the National Health Insurance Act, 1922.

A Case of Dementia Præcox.

Captain ERSKINE-BOLST asked the Minister of Pensions whether he was aware that John Ernest Taylor, M.M., late 8th City of London Post Office Rifles, was at present in the mental hospital, Claybury, suffering from shell-shock; that when he, in a fit of depression, tore a bed sheet, he was placed in a small shuttered and darkened room with several lunatics, without sufficient clothing; that, when visited by his parents on April 8th and 9th, he was shivering and had developed a chill; and that the mother was informed on April 22nd by the doctor that her son had been vomiting and was not expected to recover; and whether he would take steps to have this patient removed to a shell-shock or convalescent home and institute inquiries into the conduct of the officials concerned at Claybury.—Lord EUSTACE PERCY replied: The Board of Control have seen the medical superintendent of Claybury and inquired fully into the circumstances of this case. The patient, James (not John) Ernest Taylor, is suffering from dementia præcox. He is at times violently impulsive and destructive. On April 5th he destroyed a sheet and pillow cases and was placed in a side room which, for his own protection, had the shutters of the window closed. It is not a fact that other patients were in this side room with him, or that he was without sufficient clothing. The medical officer who has had charge of the case since December states that the patient has never suffered from a chill while under his care. The patient vomited on April 23rd and was seen by the medical officer, who prescribed for him, and on the following day he had recovered from this attack. Mrs. Taylor, who visited her son on April 23rd, was informed that his mental prospects were poor, not that his general health was critical; he is, in fact, physically a strong and healthy man. My right hon. friend is advised that the patient is not at present a suitable case to be treated outside a mental hospital. During his residence at Claybury he has attacked and seriously injured three attendants, one of whom was off duty for six weeks.

THURSDAY, MAY 3RD.

Reconsideration of Conditional Assessments.

Mr. BROTHERTON asked the Minister of Pensions what provision was made in the case of men suffering from bronchitis and/or asthma who appealed on the grounds that they were under-assessed; and whether men suffering from these disabilities, on home treatment without allowances, could have the same privilege extended to them as was given to the men on in-patient treatment with allowances—i.e.,

that they might be boarded when ill and not, as at present, have to wait until they had recovered from the attack of sickness that incapacitated them from work before the appeal to the medical appeal board was considered.—Major TRYON replied: The right of application for reconsideration of a conditional assessment applies equally to all disabilities, and the instructions do not, as the hon. Member appears to think, preclude applications of this nature being dealt with when the man is undergoing home treatment without allowances.

MONDAY, MAY 7TH.

Medical Appointments in Cumberland.

Mr. GAVAN-DUFFY asked the Minister of Health if, before giving his sanction to the appointment of a medical officer of health for the urban district area of Frizington, Cumberland, take into serious consideration the recommendation of the county of Cumberland medical officer of health that several of the small urban areas should, in the interest of efficiency and the proper administration of the laws of public health, be amalgamated under one full-time medical officer instead of the present system of appointing officers who could do no effective work as medical officers of health without sacrificing the interests of their panel patients.—Lord EUSTACE PERCY replied: My right hon. friend has received no formal representation for the issue of an Order to combine this with other districts for the purpose of appointing a whole-time officer. He has, however, tried to arrange for such an appointment to be made by agreement. As these efforts have not been successful, he has not thought it practicable to object to the district council's proposals to appoint a part-time officer, who has, however, been required to give a written undertaking to resign the appointment in the event of a whole-time officer being appointed. My right hon. friend cannot accept the suggestion that no effective work can be done by part-time medical officers of health without prejudicing the interests of their panel (or other) patients.

Education of Mentally and Physically Defective Children.

Mr. ROBERT MORRISON asked the President of the Board of Education how many local educational authorities made special school accommodation for mentally and physically defective children during 1922; how many authorities were permitted to open new special schools; how many were refused; and, of those refused, on what grounds.—Lord EUSTACE PERCY replied: During the year ending Dec. 31st, 1922, 90 local education authorities in England and Wales were providing special school accommodation for mentally or physically defective children. Five authorities were allowed, and seven were, on financial grounds, refused permission to open new schools.

Water Supplies in Rural Districts.

Colonel Sir ARTHUR HOLBROOK asked the Minister of Health whether he would consider, as one method of relief works for the unemployed, the supply of water to rural districts in which at present water had to be brought from a distance, thus ensuring an ample supply of pure water, which was necessary for the preservation of health.—Lord EUSTACE PERCY replied: Schemes of this kind submitted by local authorities will be considered if the degree of local unemployment is sufficient to warrant this course, and if the proposals are practicable from an engineering and financial point of view.

TUESDAY, MAY 8TH.

Preservatives in Food.

Mr. ALBERT BENNETT asked the Minister of Health if his attention had been called to the representations of county and borough councils, based on the advice of their respective medical officers, that a limit should be placed on the use of preservatives in food; and whether he would appoint a committee of investigation into the question, seeing that for many years the local authorities had been urging that action should be taken.—Mr. NEVILLE CHAMBERLAIN replied: The answer to the first part of the question is in the affirmative. I have already taken preliminary steps to appoint a small committee to inquire into the general question of the use of preservatives and colouring matters in food.

Appointments.

FYFE, G. M., M.B., Ch.B. Aberd., has been appointed Junior V.D. Officer at the Aberdeen Royal Infirmary.
PIATROWSKI, J. GEORGES, L.R.C.P., M.R.C.S., Second Resident Medical Officer at the French Hospital.
REYNOLDS, RUSSELL J., M.B., B.S. Lond., Honorary Adviser in Radiology to the Ministry of Pensions.
TATE, J., M.R.C.S., L.R.C.P. Lond., D.P.H., Medical Officer of Health for the Administrative County of Middlesex.
TUXFORD, R., M.R.C.S., L.R.C.P. Lond., to be one of the Medical Referees under the Workmen's Compensation Act, 1906, for County Court Circuit No. 17, Boston, Holbeach, Sleaford, &c.

Vacancies.

For further information refer to the advertisement columns.

Aberdeen Royal Mental Hospital.—Senior Asst. P. £400 to £500.
Barking Town Urban District Council.—Female Asst. M.O.H. and Asst. School M.O. £500.

Election of Officers and Council for 1923-24.
Cases will be shown.

ELECTRO-THERAPEUTICS: at 5.30 P.M.

First Annual Joint Meeting of the Section with the Röntgen Society:

The Mackenzie-Davidson Memorial Lecture will be given by Prof. A. W. George (Massachusetts General Hospital, Boston, U.S.A.) on the Pathological Gall-bladder.

There will be an exhibition of radiograms bearing on the subject of the lecture.

MEDICINE; SURGERY.

Members of these Sections are cordially invited to attend this Meeting.

The Meeting will be followed by a Dinner at the Langham Hotel at 8 P.M. The price of the Dinner (exclusive of wine) is 10s. 6d., payable at the table.

Friday, May 18th.

OTOLOGY: at 5 P.M. (Cases at 4.30 P.M.)

Annual General Meeting:
Election of Officers and Council for 1923-24.

4 P.M.

Demonstration by Mr. Richard Lake of an instrument for the deaf.

4.30 P.M.

Cases and Specimens will be shown by Dr. Dan McKenzie and others.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY, May 14th.—8 P.M., Annual General Meeting. 8.30 P.M., Reception by the President. 9 P.M., Dr. J. Walter Carr: Annual Oration on Life and Problems in a Medical Utopia. To be followed by a Conversazione.

MEDICO-LEGAL SOCIETY, 11, Chandos-street, Cavendish-square, W.

TUESDAY, May 15th.—8.30 P.M., Paper by Mr. A. H. Trevor on the Mental Treatment Bill, 1923, to be followed by a Discussion.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE, 11, Chandos-street, W.

THURSDAY, May 17th.—8.15 P.M., A Paper will be read on the Treatment of Refractory Cases of Amoebic Dysentery, by Dr. J. Graham Willmore, S.M.O., Tropical Section, Ministry of Pensions Hospital, Orpington, with a Note on Emetine Preparations for Rectal and Oral Use, by W. H. Martindale, Ph.D.

The Meeting will be preceded by a Demonstration from 7.45 P.M.—8.15 P.M., of certain drugs referred to in the Paper.

LONDON DERMATOLOGICAL SOCIETY, 49, Leicester-square, W.C.

TUESDAY, May 15th.—4.30 P.M., Specimens and Clinical Cases. (Lupus Erythematosus, &c.) 5.15 P.M., Dr. W. Knowsley Sibley: Lupus Erythematosus and its Treatment. Fellows' Monthly Dinner, Cavour Restaurant, Leicester-square, at 6.30 P.M.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

Demonstration of Clinical Cases at 3.30 P.M.

MONDAY, May 14th.—Dr. J. Browning Alexander: Medical.

TUESDAY.—Mr. Howell Evans: Surgical. (3 P.M.)

WEDNESDAY.—Mr. Norman B. Fleming: Eye Cases.

THURSDAY.—Mr. H. W. Carson: Surgical.

FRIDAY.—Dr. C. E. Sundell: Diseases of Children.

LONDON HOSPITAL MEDICAL COLLEGE, Mile End, E.

TUESDAY, May 15th.—5.15 P.M., Dr. Millais Culpin: Dreams.

WEDNESDAY.—4.15 P.M., Dr. W. M. Feldman: Germinology.

FRIDAY.—5.15 P.M., Dr. Millais Culpin: Symptomatology.

Births, Marriages, and Deaths.

BIRTHS.

COFFIN.—On May 3rd, at 2, Meadow Close, Golders Green, N.W. 11, to Mr. and Mrs. Stephen Coffin—a son.
COVENTON.—On May 3rd, the wife of Dr. A. W. Duncan Coventon, The Chantry, Aylesbury, Bucks, of a son.
COX.—On May 5th, at Avenue-road, Highgate, the wife of Dr. Hedley Chave Cox, of a son.
HUR.—On April 28th, at 192A, West End Lane, London, N.W. 6, the wife of D. V. Giri, L.R.C.P. & S. Edin., L.F.P.S. Glasg., D.P.H. Lond., D.O. Oxon., of a son.
McCRAE AITKEN.—On May 2nd, at Park-street, W., the wife of D. McCrae Aitken, F.R.C.S., of a son.

MARRIAGES.

HOLMES—ROBINS.—On May 1st, at St. Andrew's, Hove, E. Arthur Holmes, M.R.C.S., to Betty May, elder daughter of Mr. and Mrs. Frank Robins, of Brunswick-place, Hove.

DEATHS.

DAVIES.—On May 2nd, at Blackheath, Langford George Davies, M.A., M.B., B.C. Camb., M.R.C.S., L.R.C.P. Lond., late R.A.M.C. and R.A.F., aged 42 years.
HUNT.—On May 6th, at Crouched Friars, Colchester, Edgar Atlee Hunt, F.R.C.S., J.P., aged 69 years.
B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY, May 14th.—12 noon, Mr. Simmonds: Applied Anatomy. 2 P.M., Mr. Addison: Surgical Wards. 3 P.M., Mr. Simson: Diseases of Women.
 TUESDAY.—11 A.M., Dr. McDougal: Electrical Dept. 12 noon, Dr. Burrell: Chest Cases. 2.30 P.M., Mr. Tyrrell Gray: Surgical Wards.
 WEDNESDAY.—10 A.M., Dr. Saunders: Medical Diseases of Children. 11 A.M., Mr. Simson: Gynaecological Demonstration. 2 P.M., Mr. Gibb: Eye Dept.
 THURSDAY.—12 noon, Mr. Simmonds: Demonstration of Fractures. 2 P.M., Mr. MacDonald: Genito-Urinary Dept. 3 P.M., Dr. Scott Pinchin: Medical Out-patients.
 FRIDAY.—10 A.M., Mr. Dudley Buxton: Dental Dept. 2 P.M., Mr. Banks-Davis: Diseases of Throat, Nose, and Ear. 3 P.M., Mr. Sinclair: Surgical Out-patients.
 SATURDAY.—9.30 A.M., Dr. Burnford: Bacterial Therapy. 10 A.M., Dr. Saunders: Medical Diseases of Children. 10 A.M., Mr. Banks-Davis: Operations on Nose, Throat, and Ear.
 Daily 10 A.M. to 6 P.M., Saturdays, 10 A.M. to 1 P.M. In-patients, Out-patients, Operations, Special Departments.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C. 1.

POST-GRADUATE COURSE: MAY-JUNE, 1923.

CLINICAL LECTURES AND DEMONSTRATIONS.

MONDAY, May 14th.—2 P.M., Out-patient Clinic: Dr. Hinds Howell. 3.30 P.M., Aspect of Nervous Disease, Clinical and Pathological: Dr. James Taylor.
 TUESDAY, May 15th.—2 P.M., Out-patient Clinic: Dr. Grainger Stewart. 3.30 P.M., Cerebral Tumours: Dr. Risien Russell.
 THURSDAY, May 17th.—2 P.M., Out-patient Clinic: Dr. Kinnier Wilson. 3.30 P.M., Clinical Varieties of Paraplegia: Dr. Walshe.
 FRIDAY, May 18th.—2 P.M., Out-patient Clinic: Dr. Gordon Holmes. 3.30 P.M., Treatment of Cerebral Tumour: Mr. Sargent.

COURSE OF LECTURES ON NEURO-PATHOLOGY.

MONDAY, May 14th.—12 noon, Cerebro-Spinal Fluid: Dr. J. Godwin Greenfield.

A COURSE OF 12 LECTURES ON THE ANATOMY AND PHYSIOLOGY OF THE NERVOUS SYSTEM will be given at 12 noon on TUESDAYS and FRIDAYS if there are sufficient entries for it.

Mr. Armour and Mr. Sargent operate at the Hospital on Tuesday and Friday mornings at 9 A.M., or at such other times as may be announced.

The fee for the whole Course is £12 12s., including Anatomy and Physiology, but these Lectures may be taken separately for a fee of £4 4s. The fee for the Course without Anatomy and Physiology Lectures is £10 10s. Special arrangements as to fees will be made for those unable to take the whole Course. Fees should be paid to the Secretary of the Hospital at the Office on entering for the Course.

C. M. HINDS HOWELL, Dean of Medical School.

NATIONAL HOSPITAL FOR DISEASES OF THE HEART, Westmoreland-street, Marylebone, W. 1.

THURSDAY, May 17th.—5.30 P.M., Dr. R. O. Moon: Heart Disease in Childhood.

INSTITUTE OF PATHOLOGY AND RESEARCH, St. Mary's Hospital, Paddington, W.

THURSDAY, May 17th.—4.30 P.M., Prof. F. G. Hopkins: An Oxidising Agent in Living Tissues.

LONDON SCHOOL OF MEDICINE FOR WOMEN, 8, Hunter-street, W.

TUESDAY, May 15th.—5 P.M., Prof. A. L. McIlroy: Toxæmias of Pregnancy.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.

THURSDAY, May 17th.—4 P.M., Dr. Nabarro: Syphilis in Infancy and Childhood.

INFANTS HOSPITAL, Vincent-square, S.W. 1.

MONDAY, May 14th.—6 P.M., Dr. Eric Pritchard: Physiology and Pathology of the Digestive System.

TUESDAY.—8.45 P.M., Dr. Eric Pritchard: Principles of Infant Feeding.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone-road, N.W.

THURSDAY, May 17th.—5 P.M., Mr. J. B. Banister: Some Difficulties in the Puerperium.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE LECTURES.

TUESDAY, May 15th.—4.15 P.M., Dr. A. H. Holmes: Massive Collapse of the Lung.

SALFORD ROYAL HOSPITAL.

THURSDAY, May 17th.—4.30 P.M., Dr. Bythell: The Bismuth Meal: with special reference to Gastroptosis.

UNIVERSITY OF BRISTOL POST-GRADUATE DEMONSTRATIONS (in the Medical Theatre).

THURSDAY, May 17th.—3.30 P.M., Mr. C. F. Walters: Modern Treatment of Stricture and Prostatic Cases.

Notes, Comments, and Abstracts.

SOME PROBLEMS IN THE LIGHTING OF PRINTING WORKS.

Abstract of a Paper read before the Illuminating Engineering Society on April 24th, 1923.

BY L. GASTER.

I MAY take as a starting-point a sentence in Mr. F. W. Goodenough's paper¹ read before this Society in 1912: "I doubt if there exists any industry in which good lighting has more effect on the successful running of the concern than is the case in the printing trade." The product of both journalists and printers is prepared exclusively for exhibition to the eye. An idea of the loss that may arise by inadequate lighting is afforded in a contribution by Mr. F. H. Bernhard to the *Electrical Review* (U.S.A.). In a large printing works it was found that after the conditions of illumination had been thoroughly modernised the general efficiency of work was improved by 25 per cent.²

Printers as a whole, and compositors especially, are probably above the average of workmen intellectually, working as they do continually with the eye and the brain as well as the hands. They are, therefore, more sensitive to working conditions and appreciative of their improvement. I understand that defects of eyesight are exceptionally frequent among compositors, which fact may be ascribed partly to work under inadequate lighting.

Value of a Well-Planned Scheme of Lighting.

In most sections of a works the aim should be to provide general illumination by lighting units of high candle-power, placed high up so as to be out of the range of view. A series of drop-lights terminating in lamps of small candle-power is inefficient, unsightly, and inconvenient. Nevertheless, the general lighting sometimes requires to be supplemented by a few local units, as many printing processes require lighting of this nature. In one respect the printing industry has an advantage over some other trades. Each machine has its allotted task and is invariably used for the same purpose. It is worth while, therefore, to scheme out suitable lighting, recognising that it should not require continual adjustment, as may happen in factories where the nature of the work and the duties required from machines change from time to time.

Although the procedure has recently been modified by the introduction of automatic type-setting machinery, the lighting of compositors' "frames" still forms an important problem. I have observed three main methods of lighting: (1) Unshaded or imperfectly shaded lamps placed over the centre line so as to illuminate the racks on either side; (2) lamps equipped with suitable reflectors used in the same way; and (3) general lighting from overhead lamps—e.g. semi-indirect lighting with sources situated between benches so that the light comes over the worker's shoulders. The first method cannot be recommended. The exposed filaments are troublesome to the eyes of the workers and the proportion of light reaching the frames is very small. But if the lamps are equipped with suitable reflectors and their distance above the top-line of the bench is suitably selected, it is possible by method (2) to obtain very good illumination on the actual inclined face of the bench. Some compositors still prefer local lighting of this description. It is, however, usually desirable to supplement this mode of lighting by general illumination from overhead sources: (a) In order to throw light on the drawers below the inclined face, which would otherwise be insufficiently illuminated; (b) to ensure adequate lighting of gangways between benches; and (c) to eliminate an undue contrast between the illuminated rack and the surroundings.

The alternative method of depending on overhead light is much more feasible with modern illuminants than with the low candle-power lamps of the past. It has the merit that the light comes from above and behind the worker and there is less likelihood of inconvenient reflection from the surface of the bench. In addition, the drawers receive a better illumination. Thus, in a recent installation of this kind it was found that the illumination on the racks was 6-8 foot-candles, and even drawers quite low down still received 1 foot-candle.

In the discussion before the Society in 1912 values in general ranging from 5-10 foot-candles (average) were recorded. In view of the fact that considerable variations in illumination at different points on a bench are often in evidence, it would seem that the average illumination whether provided by general or local lighting, should lie within these limits. In good modern installations 5 foot-

¹ *Illuminating Engineer*, 1912, v., 171.

² *Elec. Review*, U.S.A., August 24th, 1918.

andles is doubtless usual. But there are still many works where much lower values would be recorded.

Local Lighting.

The lighting of linotype or monotype composing machines, where manuscripts are "tapped out," is usually effected by adjustable local lights placed about 18 inches above the keys and screened on the side facing the worker. This is a process that needs strong local lighting, as the operator has not only to see the keys, but to distinguish the more or less illegible handwriting of the contributions he is dealing with. Such sources need very careful shading. Average values recorded by Mr. J. Eck for linotype machines were up to 5 foot-candles on the matrix box, 4.3 on the keyboard, and 4 on the copy. A recent test in a printing works by the author gave 4-8 foot-candles on the keyboard, 4-8 on the "copy," and 4 on the setting drum (measured vertically)—the latter being a particularly important spot in view of the small letters and numbers on the drum that have to be distinguished. It would appear that the illumination of the manuscript, at any rate, should not be less than 4-5 foot-candles, in view of the small type or imperfect handwriting that the operator frequently has to decipher.

Diffused Light.

In machine rooms it is obviously desirable that the surroundings should be light in colour and the illumination very fully diffused, so that all interstices in complicated machinery are clearly revealed. I would suggest that, in the interests of safety, the illumination at floor-level should not be less than 0.5 foot-candles, irrespective of the illumination provided for the actual work. On laying-on and taking-off tables, where sheets are placed and inspected, a value of about 5 foot-candles is desirable, and this value is exceeded in some well-lighted works recently visited. The point may be raised whether, for the examination of first sheets, general diffused lighting is sufficient. The printer, in judging the impressions of type and blocks, is guided very largely by small indentations in the paper, and it is possible that these could be revealed more fully by oblique unidirectional lighting. It might, therefore, be a good practice to supplement the general lighting by a local adjustable fitting, the position of which with regard to the paper could be altered according to the needs of the operator. In this department the importance of good lighting can hardly be overestimated. Any fault in the running of machinery is much more difficult to detect and remedy if the lighting is insufficient. The author has met cases in which constant breakdowns and exasperating delays were occurring in a badly-lighted room, but practically ceased when modern and adequate illumination was installed.

Illumination of Machinery.

The proper illumination of the machinery, especially the large rotary presses of the present day, is something of a problem. The conditions resemble somewhat those met with in textile factories. One may do everything possible by the placing and shading of the permanent general lights, and by the use of light surroundings, to promote good diffusion of light, but it is hardly possible by the aid of general illumination alone to ensure that all the requisite parts of such complex machinery will be well illuminated and clearly seen. This is a question that might well receive some attention from designers of such machinery, who should bear in mind the desirability of important parts being easily accessible and readily inspected. They might go further and embody in the design of the machine suitable facilities for the permanent mounting of supplementary protected lamps illuminating the vital parts where adjustments are made. In the absence of such facilities the attendant must rely on the use of portable lamps or special pendant lights at essential points. It is a matter of principle no unprotected lamp should be inserted within the machine, as the trouble arising in the event of a lamp being broken would be considerable. The lamps must be so situated or used that a flood of light can be directed on the part inspected without the operator's eyes being dazzled by glare from an exposed mantle or filament, or inconvenient shadows being cast by his body. In rooms for packing and despatching the conditions of illumination are simple, and in lofty rooms semi-indirect lighting affording 2-3 foot-candles should answer requirements.

Differentiated Lighting for Various Processes.

In the following table are assembled figures showing the great variations met with in different works for identical processes, and also as an indication that the values indicated in the Home Office Report are such as can readily be complied with in practice. While practice in different works varies, it should be possible, by means of tests conducted in co-operation with those employed in the industry, to determine desirable minima based on scientific investigation. It must, of course, be recognised that the mere provision of suitable numerical values of illumination alone is not sufficient to ensure adequate lighting; attention must be

paid to such important factors as absence of glare, avoidance of inconvenient shadows, &c.

Process.	Illumination (foot-candles).			
	Limits of values given by Mr. Eck and Mr. Goodenough.	Author's tests in 1923.	Home Office Third Report, Recom- mended minima.	Am. Illuminating Engineering Society (Industrial Practice)

Block-Making.

Engraving processes are frequently mentioned as an instance of "fine work" requiring specially high illumination; here local adjustable lights seem desirable in addition to moderate general lighting. In etching and lithography operators seem to prefer a very highly diffused source, with an extensive luminous area, which is reflected in the more or less polished material in which they are working. Colour-printing, again, is a process requiring highly-specialised illumination, as one needs not only an exceptionally high illumination, but a quality of light enabling colours to be revealed in the same manner as by daylight. Developments in "artificial daylight" are of very great interest to colour printers, and in many cases the system has been used with benefit and has enabled work to be carried on successfully when daylight failed. The aim should be to concentrate the light at the place of inspection, which should be screened from the general uncorrected artificial illumination, and to obtain an illumination which approaches normal daylight not merely in colour but also in intensity.

Examination of "Copy."

It is singular that in some newspaper offices where the need of good lighting in the printing section has been fully recognised, the editorial department conducts its work in very meagre and inadequate light. The matter sent in to a newspaper is still largely written by hand, often in hurried and crabbed writing and on flimsy paper. Even matter presented in proof often does not compare favourably with the appearance of the type in the finished production. An editor's or sub-editor's room should contain suitable general lighting preferably of the semi-indirect type, supplemented by a well-shaded table lamp. Proof-readers, also, in general would prefer a special lamp over their work.

THE METROPOLITAN ASYLUMS BOARD
AMBULANCE SERVICE.

IN THE LANCET of April 21st we referred to the questions recently raised in the press and elsewhere concerning ambulance arrangements in London, and to the need for more ambulances for the use of the three authorities—the London County Council, the Metropolitan Asylums Board, and the St. John Ambulance Association—which direct ambulance services in the London area. In view of the public interest roused, the Ambulance Committee of the Board submitted a report which was adopted on May 5th, with a recommendation that a copy be forwarded to the Ministry of Health. The Board have six ambulance stations situated in different parts of London, and a large repair depot at Fulham. They have at these stations 107 motor ambulances and omnibuses, apart from a number of motor goods lorries and tractors. The primary function of the Board's ambulance service is the removal of cases of infectious disease in the Metropolis. The Board also remove a considerable proportion of the patients in their other institutions for tuberculosis, sick and convalescent children, and mental defectives. They undertake, with their motor transport service, a substantial portion of the transport of goods from their central stores for their institutions.

History of the Metropolitan Ambulance Service.

In 1906 a departmental committee of three members was set up by the Home Secretary to inquire as to the provision of and possible improvement in ambulance service for "cases of accident and sudden illness occurring in streets and public places within the Metropolis." This committee heard a great deal of evidence and reported in December, 1906. Two of the members reported in favour of an extension of the non-infectious service of rapid ambulances initiated by the Metropolitan Asylums Board, working in close co-operation with the Metropolitan Police. The third member was of opinion that the London County Council should be the authority for the street accidents ambulance service. A good deal of emphasis was laid at that time upon the desirability of keeping the infectious ambulance service and the street accident service distinct. In 1909 the Metropolitan Ambulances Act was passed, empowering the London County Council to establish and maintain, or to contribute towards the cost of or otherwise to aid in establishing or maintaining, an ambulance service for dealing with cases of accidents or illness (other than infectious diseases) within the County of London. In November, 1913, the County Council invited the Board to prepare a scheme of co-operation with them and other metropolitan authorities for the establishment of a street accident ambulance service, and in the same month the Board prepared and submitted a complete scheme for dealing with this matter. It was, however, not accepted, and the Council proceeded themselves, in 1915, to set up the existing street ambulance service. Meantime, the Board's ambulance service had, apart from its normal work, been largely utilised for the removal of non-infectious cases from private houses to hospitals, and it has continued to meet this need.

The following statistics show the extent of the removal of patients carried out by the Board in recent years, viz. :—

	Year ending Dec. 31st.		
	1920.	1921.	1922.
To the institutions of the Board—			
(a) Infectious	36,594	48,547	33,679
(b) Non-infectious	3,859	4,361	4,807
Other removals—			
From home to hospital, infirmary, or elsewhere, or on return journeys.	18,827	13,610	13,281
Total	59,280	66,518	51,767

Present Positions of the L.C.C. and M.A.B. Services.

In the case of removals of private persons from their houses to hospitals or other addresses, the Board charge a fee for the use of the ambulance. For removals within the administrative County of London the fee is a fixed one of 10s. per journey, with an additional charge when a nurse is supplied. Outside the County of London a mileage rate is fixed; the removal of sick patients has been satisfactorily undertaken to distances up to 200 miles from London. In this matter of charging for ambulance service, the Board's service differs from the street ambulance service of the County Council, which is free, but the Board's charge is low, and in the great majority of cases has been paid without demur. No urgent case has been refused through failure to produce the amount charged at the time of removal, and in cases of poverty or distress applications relating to the charge have received favourable consideration.

The present position is, therefore, that the London County Council have provided a free ambulance service to deal with street accident cases, while the Board have a service which deals with infectious and other hospital removals, and is thoroughly adequate to deal with all demands for removals of all kinds, other than street accidents—e.g., from private houses or dwellings in London. It is, of course, impossible to guarantee in a town the size of London that there would never be the slightest delay of any kind in removing a patient. The County Council have recently published a record of their work, and in regard to that of the Board, also, complaints of delay have been almost negligible, having regard to the great and fluctuating demands it meets. The Board never refuse an urgent call either within the County of London or from over the border, but they do not encroach upon the street accident service, nor is there any occasion for the latter, as a rule, to enter the field covered by the Board's service. The Board have always been ready to work in cordial co-operation with the Council and any other authority maintaining or requiring ambulance services. The vast majority of house removals are effected on medical advice, and steps are being taken to acquaint every medical practitioner in London of the method by which the Board's ambulances, with or without nurses, may be promptly obtained at any hour of the day or night. The Commissioner of the Police has been informed that the Board's ambulances are available for police calls at any time for removal from houses in London and that the question of payment will be dealt with after the removal.

THE WORK OF THE FRIENDS' RELIEF COMMITTEE.

THE ninth report of the Emergency and War Victims' Relief Committee of the Society of Friends covers the year from April 1st, 1922, to March 31st, 1923. The well-known work of relief, which began in France, will have its permanent memorial in that country in the shape of the maternity home opened at Châlons-sur-Marne in June, 1922. This maternity home is the successor of the emergency maternity hospital opened by the committee in December, 1914; the number of births during the year was 220. A department for children under two years, and ante-natal and nursing care, further the maternity and child-welfare work of the hospital.

Russia.

The work of famine relief in the Buzuluk area of Russia—an area roughly the size of Yorkshire and Lancashire, formerly having a population nearing half a million, of whom one in three died during the famine—will, it is hoped, be terminated after the next harvest. Since last summer, when typhus and other epidemics had spread widely, and cholera was feared, health conditions have greatly improved, although malaria has been prevalent. Dr. M. D. Mackenzie, medical officer of the Friends' Mission, has organised the medical side of the work; an epidemic hospital at Buzuluk was reopened, and entire responsibility for six months' upkeep assumed by the mission. Ten other hospitals have received equipment and food enabling them again to be opened. 80 institutions have received instruments, drugs, and vaccines, and cholera vaccine sufficient for 100,000 persons was distributed to local medical men. A sanitary guard was established at Buzuluk station to watch for typhus, and a communal laundry was repaired and set in order in the town. A bacteriological laboratory has also been set up for blood-testing purposes. In all this work Russian doctors take an active part; complete arrangements have been made for handing the organisation over to them when the mission leaves the country.

Austria and Poland.

From Austria and Poland, also, the committee hopes to withdraw its workers during the summer. Here the chief medical interest of their activities has recently lain in preservation of the standard of tuberculosis dispensary work and child welfare organisation. The supply of meals to university staffs and students has now been discontinued in Poland; that in Austria continues, and has been several times referred to with great appreciation by our medical correspondent in Vienna.

The committee is now appealing for funds to complete its great work. During the period under review the London expenditure was over £300,000, of which the English administration expenses amount to 3.79 per cent. Donations should be sent to the Friends' Relief Committee, 10 and 11, Fetter-lane, London, E.C. 4.

METRIC EQUIVALENTS.

WE have received from Mr. A. E. Bawtree, F.R.P.S., a card containing scales for finding metric equivalents at mensuration results without calculation. Sixteen scales are printed on the inside of a card, which, when folded, measures 5 in. by 4 in. Each scale has the English quantitative divisions on one side of a line, and the metric divisions on the other, so that readings can be instantly taken either way. Into their metric equivalents Nos. 1, 2, and 3 convert miles, yards, and inches; Nos. 4, 6, and 7 convert square yards, square inches, cubic yards, and cubic inches; No. 8 deals with pressure in pounds per square foot; Nos. 9, 10, 11, and 12 deal with tor pounds, grains, and fluid ounces and also indicate gallons; Nos. 13, 14, and 15 compare Fahrenheit and Centigrade thermometer scales over a range from absolute zero to 2000° C.; No. 16 gives the circumference of a circle when the radius is known, and from this information with regard to spheres, cylinders, and cones is readily found. Students and teachers in many branches of learning, businessmen, and all whose work or hobby brings them into contact with these calculations will find the cards useful. They can be obtained, price 1s. each, post free, from Mr. Bawtree, 7, Manor Park-road, Sutton, Surrey.

Humagsolan Tablets.—These tablets (see THE LANCET, March 31st, p. 658) are coated with the usual silver deposit as an extra protection to the ingredients.

Hospital Saving Association.—The address of the Association is now 77, Cambridge-terrace, London, W. 2 (telephone: Paddington 1653). Mr. F. B. Elliot is the general secretary.

A Lecture

ON THE

PHYSIOLOGY OF INSULIN.

*Delivered in the Institute of Pathology and Research,
St. Mary's Hospital, on May 10th, 1923,*

By H. H. DALE, C.B.E., M.D. CAMB.,

F.R.C.P. LOND., F.R.S.,

DEPARTMENT OF BIOCHEMISTRY AND PHARMACOLOGY,
NATIONAL INSTITUTE FOR MEDICAL RESEARCH.

To realise the significance of the discovery of insulin we have to go back nearly 40 years. Before 1885 there had been suggestions, based on post-mortem observation, of some connexion between the pancreas and diabetes; but I think it is extremely improbable that clinical and post-mortem observation alone would, even yet, have produced any clear evidence that diabetes is due to a defective function of the pancreas.

GROWTH OF VIEWS ON PANCREATIC FUNCTION.

Before 1885 the experimental evidence in favour of this view was certainly no clearer. Its results, so far as the pancreas was concerned, were chiefly negative. Claude Bernard¹ and Schiff² had shown that the pancreatic ducts could be blocked with paraffin, excluding the pancreatic juice from the intestine and eventually causing fibrosis and shrinkage of the organ, without any serious impairment of the animal's health. It was, therefore, quite clear that diabetes had no connexion with the only function of the pancreas then known—viz., that of forming a digestive juice. Various other workers, from 1682 onwards, had attempted to remove the pancreas by operation, but they failed to extirpate it completely, and no diabetes was recorded. On the other hand, the work of Claude Bernard³ had demonstrated the possibility of producing a glycosuria by indirect stimulation of the nerves to the liver, and the general impression left by combining clinical with experimental results was that, when diabetes was associated in man with some lesion of the pancreas, this resulted from an involvement of the solar plexus. Then, in 1885, the position was completely changed by v. Mering and Minkowski's⁴ success in removing the pancreas completely from dogs, and their demonstration that this operation was regularly followed, within a day or two, by the appearance of a condition resembling severe diabetes mellitus in man, in practically all respects. Among those who confirmed this observation Lepine⁵ appears to have been the first to suggest definitely that it indicated the production by the normal pancreas of an internal secretion, necessary for the proper metabolism of carbohydrates and fats. Others, such as Pflüger, long clung to the view that the effect of the operation was not due to loss of the pancreas, but to the injury of nerves to the duodenum. Lepine's view, however, was fully established when Minkowski⁶ and also Hédon⁷ showed that when a portion of the pancreas was first grafted successfully under the skin of the abdomen, the rest of the gland could subsequently be removed with impunity, diabetes only appearing later and gradually as the grafted portion became sclerosed and degenerated, or immediately if it was removed by a small, second operation. The suggestion was made independently by Schafer and by Diamare⁸ that the internal secretion was produced, not by the ordinary secreting acini of the gland, but by the so-called islets of Langerhans. There was at that time no direct evidence in favour of the supposition, and only the suggestive fact that these islets were richly supplied with blood capillaries. Later was discovered (Schultze⁹) the fact, important in the history of insulin, that if the pancreatic duct was blocked with paraffin, the sclerosis of the gland which followed, and which was already known not to entail the appear-

ance of diabetes, destroyed the ordinary secreting acini, but left the islets with their circulation, and presumably their function intact.

THE ISLETS OF LANGERHANS AS SOURCE OF AN INTERNAL SECRETION.

A presumption being thus established in favour of the islets as the source of an internal secretion from the pancreas, and of defect in their function as the cause of diabetes, the pancreas from fatal human cases of the disease was the object of diligent histological examination all over the world, but the results were indefinite. Some observers, such as Wechselbaum and Stangl,¹⁰ and Opie,¹¹ described degenerative changes in the islets from such cases, but in very many instances observers failed to detect any change. The histological methods then available were, indeed, inadequate for its detection; and even when the methods for staining and recognising the different kinds of cells in the islets were developed by Lane¹² and Bensley,¹³ their successful use demanded material of such perfect freshness that they can very rarely, even now, be properly applied to the human pancreas obtained at post-mortem examination.

Here, again, we have to depend, for the next item of definite information, on experiment. Allen,¹⁴ as the result of his experiments on dogs, had found that a small remnant of pancreas, sufficient to maintain the animal's health on a restricted diet, would break down in its function if a diet were given in excess of its power of control. The breakdown might in this way be made permanent. This observation, with its close analogies to the effect seen in the diabetic man who breaks his dietary discipline, enabled Allen¹⁵ later to compare the histology of the islets in a still normally functioning pancreatic remnant with those in a similar portion, whose function had been broken down and permanently destroyed by overwork. The result was highly instructive. Of the two types of special cells, so-called α and β cells, with differently staining granules, which had been shown by Lane and Bensley to exist in the islets, the α cells apparently suffered not at all in the functional breakdown, while the β cells lost their granulation, became vacuolated and distended, burst and disintegrated altogether. By taking the condition in time, and resting the β cells completely by a period of starvation, they could apparently be brought to recovery.

The whole story, then, seems to have been brought into reasonable order on that side; diabetes mellitus is apparently due to a breakdown in the function of the islets of Langerhans, and especially of their β cells. Naturally weak in the individual, perhaps, or with a resistance impaired by some infective or toxic agent, they give way to the least overstrain thrown on them by the diet; if taken in time they can be partially restored by dietary rest, but remain permanently weakened and liable to further breakdown. Thus has been rationalised the treatment of diabetes by resting the defective pancreas, introduced by Allen as the result of his earlier experiments, and, to give credit to scientific clinical work and to our own countryman, arrived at simultaneously by G. Graham as the result of careful and quantitative observations on human patients.

Meanwhile a large number of efforts, made by different workers, to prepare from the normal pancreas an extract containing the missing principle, in sufficient strength to make good the defect in the artificially diabetic dog, or the naturally diabetic man, were almost wholly unsuccessful. Administration by the mouth of fresh or dried pancreas, or various forms of extract, has been tried and tried again, and is apparently still being used by some. The evidence we now have, as to the nature of the active principle, makes it incredible that any significant quantity of this, even if present in the preparation used, would escape the destructive action of the digestive juices. Extracts of various kinds given by hypodermic or intravenous injection gave results at best equivocal. Starling and Knowlton¹⁶ believed they detected an effect of a boiled watery extract of pancreas on the

sugar-consuming power of the heart from a diabetic dog. This, though it received confirmation from Starling and Evans's¹⁷ determinations of respiratory quotients under the same conditions, and from Maclean and Smedley's¹⁸ experiments with artificial perfusion, was abandoned by Starling himself in a paper with Patterson.¹⁹ Murlin and Kramer,²⁰ using a similar extract, and injecting it into diabetic dogs in large quantities, obtained a suggestion of a positive effect, but came to the conclusion that it was due to alkali added to the extract before injection.

PROOF OF AN ANTIDIABETIC PRINCIPLE.

The nearest approach to a proof of the existence of an antidiabetic principle in the pancreas, in quantity sufficient for detection, was made by Kleiner²¹; but his method gave not the slightest promise of practical application. He injected large doses of unfiltered, watery emulsion of fresh pancreas into the veins of diabetic dogs. On the other hand, the nearest approach to the method, which has proved the key to the practical production of insulin, was made by E. L. Scott,²² who himself, however, described the preparation he so obtained as completely devoid of the specific action he sought to preserve. It was beyond doubt, then, that the pancreas during life produced and added to the blood a substance necessary for normal metabolism, and especially for the normal utilisation of sugar; but attempts to extract this substance and to administer it artificially had given negative, doubtful, or capricious results, affording no hope of practical application. The general impression, I believe, was that the active principle was either secreted into the blood as fast as it was formed, so that the pancreas never at any one time contained a store of it, or that, if stored in the living gland, it was so unstable that it would cease to exist almost as soon as it was extracted from the cells.

There was another alternative. The principle might be lost in extraction, not on account of an inherent instability, but because it happened to be produced by a tissue scattered, in small packets, through a gland which forms the most powerful digestive ferments in the body. This possibility must have occurred to many physiologists, who also knew that the glandular cells, forming the ferments, could be brought to complete degeneration and made to disappear by blocking the ducts of the gland, leaving only the islets intact and functional. On this view, then, from such a degenerated pancreas it should be possible to extract the active principle of the islets, in quantity sufficient to give clear demonstration of its action. Many, again, may have had this idea; but the whole field of investigation had become so littered with the traces of failure, or of success so uncertain as to be almost more disheartening, that it needed fresh minds, and enthusiasm unclouded by disappointment. Fortunately the idea presented itself to Dr. Banting, who, with the coöperation of Mr. Best, began to put it to the practical test in the medical school at Toronto.²³

EXPERIMENTAL DEMONSTRATION.

In a few months the first point was settled. A pancreas in which the ferment-forming cells had degenerated as the result of blocking the duct would yield, to simple extraction with cold saline solution, an extract, injections of which promptly reduced the blood-sugar of an artificially diabetic dog. Sugar given with the extract was partly retained and used, instead of being entirely excreted. The active principle was destroyed by boiling or by incubating with pancreatic juice, so that there was abundant reason for most of the earlier failures. Similar active extracts were then prepared from the pancreas of foetal calves, taken at a stage of development before the pancreatic ferments had appeared. Extracts from normal adult pancreas, made with acidulated alcohol, were then tried and found to contain the active principle, and by daily injections of such an extract a dog from which the pancreas had been completely removed was kept alive and healthy for ten weeks, and then killed.

With the coöperation of Mr. Collip²⁴ the investigation, which was now under the supervision of Prof. Macleod, attacked the problem of producing, from normal pancreas from the slaughter-house, an extract sufficiently stable and free from toxic concomitants to justify its trial on human patients. This was achieved by a process which, in its essence, consisted of extracting from the pancreas constituents soluble in alcohol of 80 per cent. strength, but insoluble in alcohol of 93 to 95 per cent. strength. This fraction contained most of the extracted antidiabetic principle, now called "insulin." The possibility was thus provided for large-scale use in human therapeutics. Various technical difficulties had to be overcome, and many still wait for solution, to ensure that all the insulin available in the raw material is extracted, that it is freed, as far as possible, from inert or toxic materials extracted with it, and that it is obtained in a clean, safe, and stable condition. Great progress has already been made, and the insulin now available is a very different product from that of even a few months ago. But I am not proposing to-day to deal, except incidentally, with insulin as a practical therapeutic agent. I propose rather to speak of the new possibilities of physiological investigation which are opened up by the now proven fact that this pancreatic principle can be obtained and kept in a highly active form. For, though we cannot lightly value the immediate prospect of relief from almost unbearable deprivation which it presents to many sufferers, this is a small thing in comparison with the new power of penetrating the mysteries of metabolism which insulin will give. The immediate gain for humanity is great; the ultimate gain is as yet immeasurable.

THE CHEMICAL NATURE OF INSULIN.

Let us consider first what little is known as to the chemical nature of insulin itself. No approach to its isolation in a state of chemical purity has yet been made, yet enough has been done already to make us certain that it is a very intensely active substance. By methods of fractional precipitation, which its chemical properties make possible, a dose of insulin sufficient to produce hypoglycæmic convulsion in a full-grown rabbit—an effect I shall deal with presently—can be obtained in the compass of a quarter of a milligramme or less of solid matter. Yet, such is the tendency of insulin to become adsorbed on almost any precipitate which is formed in its solutions, that we can feel fairly certain that only a small proportion of this tiny weight of material consists of insulin itself. When a solution of the impure insulin is saturated with ammonium sulphate the activity passes into the precipitate which is produced; when the reaction of the solution is made acid to a degree represented approximately by pH5, a precipitate forms at this iso-electric point, again containing the activity (Doisy, Somogyi and Shaffer²⁵). My colleague, Dr. H. W. Dudley has found what will probably be a valuable aid to the purification of insulin, in the fact that when picric acid is added to its solutions a very insoluble precipitate is formed, containing all the insulin, and that this, by appropriate means, can be converted into a soluble hydrochloride, still containing all the activity.

We have every reason to believe that insulin is a protein derivative, and a fairly complex one. It is not only rapidly destroyed by alkaline trypsin, which will split quite simple polypeptides, but also, as Dudley has recently found, by pepsin, which readily attacks only much more complicated molecules. This indicates that insulin is a much more complex body than other hormones, such as those of the pituitary body, which are practically untouched by peptic, though rapidly destroyed by tryptic digestion. Incidentally, it throws light on the fact, already determined directly by the Toronto workers, that insulin has very little if any action when it is administered by the mouth. The relatively large molecule of insulin makes difficult its absorption through intact mucous membranes. Dr. Blumgart, who in Boston had found that pituitary extract could be absorbed through the nasal mucous membrane and effectively administered by this route

or the treatment of diabetes insipidus,²⁶ has found, with Dr. George Graham, here in London, that insulin is very imperfectly absorbed from the nasal passages. "Jelfer"²⁷ has recently demonstrated that insulin can reach the circulation when it is rubbed as an ointment onto the shaven skin of a rabbit; but it is apparent from his figures that only a small part of the dose used was absorbed. Though it seems to be a fairly complex protein derivative, insulin is very stable to heat when its solution is made strongly acid. Under such conditions it will survive heating to 100° C. for half an hour. In alkaline solution it is very unstable, its activity disappearing rapidly even at body temperature.

What little we know, then, as to the chemical nature of insulin does not give any serious prospect of its isolation and of the discovery of its structure. It certainly does not approach the chemical simplicity of adrenalin, or even of thyroxin. What we can expect is that it will be obtained in a condition of higher purity and stability than has yet been attained.

ITS DISTRIBUTION IN NATURE.

The study of the distribution of insulin in nature is already given interesting, and some surprising, results. In the higher animals it seems to be strictly limited to the pancreas, and there is now direct evidence of its further limitation to the islets of Langerhans. In certain fishes, such as *Lophius piscatorius*, the angler fish, the pancreas is spread out to a thin layer in the mesentery and along the mesenteric veins. The islets are gathered into several secretory rounded masses, covered only by a film of ordinary pancreatic tissue, so that, from this fish, the islets and the ordinary glandular tissue of the pancreas can be obtained separately. Rennie and Fraser²⁸ many years ago administered islet tissue from this fish to diabetic patients, without any decisive result. Hence they mostly gave it by the mouth, a negative result, as we now know, was to be expected from nearly all their attempts. Macleod²⁹ has recently proved definitely that the *Lophius* islets are rich in insulin, while the ordinary acinous tissue of the pancreas contains none. The same result was obtained in another fish, the sculpin. In vertebrates, then, it seems beyond doubt that the formation of insulin is located exclusively in the islets of Langerhans. The suggestion, however, that its presence is essential to the normal metabolism of carbohydrate by all tissues has led several observers to search for insulin in lower forms of life. Already evidence has been given by Inter and Smith³⁰ of the possibility of extracting from yeast something having the same physiological effects as insulin, while Collip³¹ records that he has, in addition, obtained similarly active preparations from clams and from a large variety of rapidly growing vegetable tissues. These results, if confirmed, will have an important bearing on the function of insulin in vital processes generally; but for the present, at least, the vertebrate pancreas remains the only practical source for its preparation on a large scale.

ITS POWER OF REPLACING THE INTERNAL PANCREATIC SECRETION.

The results so far obtained concerning the physiological action of insulin are full of interest and promise. The diabetic animal or man it does all that could be expected from a supply of the missing internal secretion. Not only is the blood-sugar lowered rapidly, with a sufficient dose, to the normal concentration or below it; the so-called acetone bodies also, produced by abnormal metabolism of fat, disappear from the urine and the blood, lipæmia, if present, rapidly removed, and in every way, for a few hours, the subject becomes practically a normal individual, capable of taking a quantity of carbohydrate, proportionate to the dose of insulin injected, without a rise of his blood-sugar above the normal level. In a completely diabetic dog the respiratory quotient is about 0.7, indicating that the body is

burning fat and protein and utilising practically no sugar. The Toronto group have shown that, if sugar is given to such a dog, there may be a slight rise of the respiratory quotient, indicating that a very little is utilised. If sugar is given with insulin the respiratory quotient rises to a normal level of about 0.9.³² This would seem to indicate that the power of oxidising sugar is temporarily restored to the diabetic animal by supplying the missing factor, insulin. The dog without a pancreas, if sugar and insulin are administered for a few days, also regains the power of storing glycogen in the liver, which, when the animal is killed, is found to contain a good store of this substance, in contrast to that of the untreated control animal, in which the liver contains mere traces (Banting, Best, Collip, Macleod, and Noble³³). All the evidence fits well with the view that glucose can be oxidised by the tissues if insulin is present, but that in its absence they cannot deal with it, so that all the sugar-making reserves of the body are called upon to pour into the blood an excess of the food which the hungry tissues need, but cannot use.

The effects of insulin on normal animals, however, strongly suggest that the part played by insulin, though essential to the use of sugar by the tissues, is not to cause its immediate combustion. The action on normal animals, indeed, presents a series of fascinating problems, the solution of which will probably remove long-standing obscurities from the conception of the metabolism of carbohydrates. When a normal rabbit, the blood of which contains, say, 0.12 per cent. of dextrose, receives a dose of insulin the dextrose soon begins to disappear from the blood. By the end of an hour it may have fallen to 0.05 per cent., after an hour and a half to 0.03 per cent., and after two hours, if the dose of insulin has been large, there may be practically no sugar left in the blood. As the blood-sugar reaches the level of about 0.04 per cent. the rabbit shows pronounced restlessness, and a little later falls into violent convulsions.³⁴ Analogous nervous phenomena may appear in the human patient who has received a dose of insulin, excessive in relation to the supplement of his diet. They are certainly dependent on the lack of sugar in the blood, since they disappear immediately if dextrose is injected.

ITS RELATION TO THE COMBUSTION OF SUGAR.

So far the evidence seems simple enough. Excess of insulin has so accelerated the combustion of dextrose, we might suppose, that the body has used up the whole available supply in an hour or two. But such excessive combustion might be expected to reveal itself in a rise of body temperature and an accelerated respiratory metabolism. The results of actual determinations made by Dudley and Laidlaw, and simultaneously by Trevan and Boock,³⁵ are entirely opposed to this expectation. The respiratory quotient, indeed, rises somewhat at first, as though sugar were being combusted in greater proportion to proteins and fats; but the rise is due simply to accelerated output of carbon dioxide, and is not accompanied by any increase in the consumption of oxygen. If the combustion of sugar is indeed accelerated, that of the other substances must be correspondingly or disproportionately depressed. Even the rise in the respiratory quotient is an evanescent phenomenon, and by the time the blood-sugar begins definitely to fall below the normal the usage of oxygen and the output of carbon dioxide are both falling rapidly, and with them the body temperature, so that in a couple of hours in the rabbit, in half-an-hour in the mouse, the respiratory metabolism is only one-half of the normal or less, and the animal, in the intervals of convulsive seizures, lies cold and collapsed. Now this does not look at all like a mere acceleration of carbohydrate metabolism—a principal source of bodily energy and heat; it rather suggests the reverse. Kellaway and Hughes, have obtained closely similar results on the respiratory metabolism of the normal human subject, when a large dose of insulin was given during a fast.³⁶

If sugar disappears, and, as this evidence suggests, is not burned, it must be converted into something else. The first and most obvious suggestion is that it is converted into glycogen, and accumulated in this form in the liver or the muscles. This is certainly not the case. By the time a rabbit or a mouse has reached the stage of insulin convulsions, Dudley finds that a large part, in some cases practically the whole, of the normal glycogen has disappeared from the liver and the muscles as well. So that the process of removal of sugar, whatever it may be, has accounted not only for what was circulating as such in the blood, but also for the much larger quantity potentially available in the form of glycogen in the liver and the muscles. Another possibility, which we have tested, is that the sugar may be converted into fat. Such a conversion would well explain the preliminary rise in the respiratory quotient. But Dudley has found no evidence that it occurs; the liver of the animal poisoned by excess of insulin contains neither more, nor significantly less fat than that of the normal animal.

Experiments on isolated organs have as yet given but little help. Hepburn and Litchford,³⁷ indeed, have found that dextrose disappears from Locke's solution, circulated through the isolated heart, at three or four times the normal rate, if insulin is added to this solution. Before the discovery of insulin Clarke³⁸ had shown that the isolated heart removed sugar more rapidly from Locke's solution if the latter was first perfused through the pancreas. But there is no evidence yet that the sugar so removed is burned; if it were, indeed, the heart might be expected to put out energy at three or four times the normal rate, and there is certainly no evidence of this. We are left with the same problem as that presented by the whole animal. Sugar disappears, but we do not know how.

PRESENT POSITION OF KNOWLEDGE.

That is the state at present of the question as to the mode of action of insulin. There is no doubt whatever that its presence in the body in some way is essential to the use of sugar by the tissues, and that it can restore the power of using it to the diabetic; but the manner of its intervention remains dark. Some will doubtless suspect a connexion between these apparent anomalies and the evidence produced, in recent years, to show that the tissues do not use dextrose directly as such, but after its conversion into a hexose phosphate (Emden³⁹), for which, according to one suggestion (Laquer⁴⁰), the dextrose must pass through the form of glycogen as an intermediate stage. Winter and Smith⁴¹ have recently put forward some highly suggestive evidence in support of a theory that the sugar in normal blood is not ordinary $\alpha\beta$ glucose, but a reactive form having similarities with the so-called γ -glucose. (For difficulties in the way of this identification, see Hewitt.⁴²) Winter and Smith suppose that the function of insulin may be to catalyse the conversion of ordinary glucose, which the body cannot burn, and with which they identify the sugar in the blood of the diabetic, into this reactive, usable form.

Neither this ingenious and attractive conception, nor any of the new evidence concerning the intermediate stages of sugar metabolism, seems to me to throw any light on our difficulty concerning the mode of disappearance of sugar from the blood of the normal animal when insulin is injected. The reactive sugar of the normal animal's blood, if it be such, disappears under the stimulus of insulin just as that of the diabetic does; and in the case of the normal animal the disappearance, in all but its earliest stages, is associated with a fall, not a rise, of the respiratory metabolism. I am inclined, myself, to suspect that the explanation is a simpler and more obvious one than any theory of the conversion of sugar into an unknown intermediate product can by itself afford. It is not, at any rate, absurd, to expect that the state produced by excess of insulin will be the direct antithesis of complete pancreatic diabetes. In the latter condition,

in the absence of insulin, the body cannot use glucose; it is at least possible that, when excess of insulin is injected, the effect is so to shift the incidence of metabolism on to the carbohydrate that the body will use practically nothing else, and supply almost all its energy needs by burning sugar, so long as the supply lasts. The result would be the preliminary sharp rise of the respiratory quotient, which actually occurs, and this would not necessarily be accompanied by an increase of total metabolism. As the supply of carbohydrate began to run low, the general metabolism would fall rapidly, until, when the blood-sugar reached a certain level, the failing combustion of this substance would be overtaken by what metabolism of protein and fat still went on, and the respiratory quotient also would fall below the normal. Direct evidence, including measurements of the protein metabolism, if we can obtain them, may prove that such a conception is untenable. But, for the present, I believe that it corresponds with what knowledge we have, and renders intelligible such phenomena as the symptoms which appear as the carbohydrate store nears exhaustion, and their almost instantaneous removal by the injection into the blood of glucose and, so far as we know, of nothing but glucose—not even of glycogen.

ANTAGONISM BETWEEN PANCREAS AND PITUITARY BODY.

There is one other item of physiological information recently acquired, which seems to me to present possibilities of great interest. It has long been known that the pituitary body, with regard to its effect on carbohydrate metabolism, has some obscure functional antagonism to the pancreas. In minor degrees of pancreatic defect a patient has a lower tolerance for sugar, so that a small quantity causes the concentration in his blood to rise to an abnormal height, with the result that sugar escapes into his urine. In defects of the pituitary body the opposite condition has been described by Cushing. The patient has a greatly enhanced tolerance for sugar, so that he can take much larger quantities than a normal man without hyperglycemia or glycosuria. Some recent observations by Burn⁴³ seem to show clearly that this is due to definite antagonism between a hormone of the posterior lobe of the pituitary body and insulin. A dose of pituitary extract which will not, by itself, cause a significant rise of the concentration of sugar in the blood, will effectively prevent, or rapidly remove already produced, the fall in blood-sugar concentration produced by a dose of insulin. The Toronto workers have described the antagonism of insulin to hyperglycemia produced by a number of different agencies—apnoea, carbon monoxide, anaesthetics, adrenalin. In all these cases, however, the effect seems to be of the nature of a balance of two actions—one increasing the rate at which sugar enters the blood from the liver, the other the rate at which it disappears from the blood. In the case of the pituitary extract the effect seems to be only explicable as a direct antagonism to the action of insulin.

CONCLUSION.

I have indicated only a few of the directions in which the discovery of insulin is already widening physiological knowledge and presenting new problems of interest. There is every indication that it will prove to have an importance for physiology and medicine far beyond that of its use in the treatment of diabetes. Meanwhile, however, it is worth our while to consider briefly what even the partial knowledge of its action, yet available, indicates as the method by which insulin can be used with greatest benefit to the diabetic. There are doubtless cases in which the natural function has been so completely lost, the islet so hopelessly degenerated, that not even a partial recovery can be anticipated. In such, insulin can prolong life and make it more tolerable, but only at the cost of daily injections which can never be remitted or reduced. Such a result is, in itself, worthy of attainment, but it seems to me that there is something

much better to be aimed at. All the experience which had accumulated before the introduction of insulin pointed to the possibility of restoring to many diabetics a reasonable measure of normal function by giving their overworked remnant of islet tissue as complete a rest as possible. In many cases this was only achieved by a restriction of diet which was almost unbearable, though still compatible with life. If insulin is now used simply to enable such patients to eat a large quantity of food so long as they can tolerate daily injections, they will get no permanent benefit, and insulin will be wasted. On the other hand, if it is used as an aid to the regime of dietary rest, to enable these patients to obtain some recovery of normal function without such cruel reduction of their diet; if it is used to bring into this class, for which some measure of restoration is possible, others in whom, without insulin, no diet sufficient for life would keep the blood-sugar down and give the overstrained islets a chance of recovery; then, indeed, it will be used to the real advantage of the patients, and be worthy of all the extraordinary enthusiasm which its discovery has aroused.

Mr. Henry Kimpton will publish shortly the first volume of Collected Papers from the Washington University School of Medicine, and a volume of Clinics and Collected Papers of St. Elizabeth's Hospital, Richmond, Virginia.

CHILDREN IN GENERAL PRACTICE.—A lecture with his title will be delivered in the Board Room of the Royal Hospital, Chesterfield, at 8 P.M., on May 30th, by Dr. H. C. Cameron, under the auspices of the Chesterfield Division of the British Medical Association. All members of the medical profession are invited to attend.

Annual Oration

ON

LIFE AND PROBLEMS IN A MEDICAL UTOPIA.

Delivered before the Medical Society of London on May 14th, 1923,

By J. WALTER CARR, C.B.E., M.D.,
F.R.C.P. LOND., F.R.C.S. ENG.,

CONSULTING PHYSICIAN TO THE ROYAL FREE HOSPITAL AND
TO THE VICTORIA HOSPITAL FOR CHILDREN, CHELSEA;
EMERITUS LECTURER IN MEDICINE, LONDON SCHOOL
OF MEDICINE FOR WOMEN.

IN 1516 Sir Thomas More published his famous work "Utopia," a description of an ideal commonwealth, or an imaginary country whose inhabitants are supposed to exist under the most perfect conditions possible. Many other writers, both before and since, have attempted a similar task, and a former distinguished President of this Society, Sir Benjamin Ward Richardson, in 1875 gave an address on "Hygeia," in which he told what a city should be if sanitary science were advanced in a proper manner. Now that we have a Ministry of Health fully established and many members of our profession strongly advocating a State Medical Service, it may be interesting to consider some of the conditions of life and some of the professional problems which would call for consideration if, not the medical profession as a whole, but—what is quite a different matter—the officials of the Ministry of Health were in a position to rule the country in a despotic manner as a benevolent autocracy. Obviously only a few points can be touched upon in a very limited time, but let us try briefly to survey the life-history of an average citizen under such a regime.

CONTROLLED MARRIAGE.

It is difficult to know where to start, but it may be convenient to commence with a young couple about to enter into the bonds of matrimony. Each one will have undergone a complete medical examination, including a careful investigation into the family history, a matter which will not depend upon the more or less imperfect recollection of the parties themselves, but on the full life-history of every citizen which will be available for reference. They will both, therefore, be provided with certificates proving that they are in every way fitted by heredity, physical fitness, and freedom from disease to undertake the responsible duty of propagating the race. They will have received also detailed instruction in all matters of sex function and hygiene, so that they may enter upon married life with the most ample knowledge of their reciprocal duties to each other and to the coming generation. A question will naturally arise as to the fate of those members of the community who fail to pass the stringent tests which will rightly be imposed upon all candidates for matrimony. We must trust that the general consensus of public opinion would suffice to prevent them from entering into irregular unions and begetting children who would probably fail to attain a proper standard of physical and mental fitness, but should such illegal occurrences unhappily become at all common the community would have to take suitable precautions in self-defence, and might decree that all adolescents should be examined at puberty and steps taken to sterilise those who could not reasonably be expected to beget healthy children. A similar operation might be performed later upon any who by reason of the subsequent development of disease became unfit for parenthood.

ANTE-NATAL PRECAUTIONS.

Our young couple, having passed the preliminary medical ordeals, are at length happily married and in due course the wife becomes pregnant. Imme-

diately upon the fact becoming known her condition will be notified forthwith to the medical officer of health, by whom she will be allotted to the nearest ante-natal clinic, and thus the unborn child will be brought within the grip of the health authorities, a grip never to be relaxed until, probably at a ripe old age, his mortal remains are disposed of, in the most hygienic manner possible—*cito, tuto et jocunde*—in the municipal crematorium.

A definite period of time will be fixed before the expected date of confinement, and also subsequent to it, during which the mother will be strictly forbidden to do any work, and special precautions will be taken to ensure that she is supplied with suitable food. At intervals throughout her pregnancy she will be carefully examined, so as to enable any complication or abnormality to be dealt with promptly, and also to obviate the necessity for a pelvic examination during the early stage of labour. Parturition amid the unhygienic surroundings of the patient's home will necessarily be strictly forbidden and in due course she will be admitted to the municipal maternity hospital, and thus the present death-rate of 0.4 per cent. from child-bearing should be reduced to an infinitesimal figure. I must leave it to the obstetricians to decide how far labour would be regarded and treated as a major operation and attempts made to sterilise the surrounding structures; but, as an indication of what the future has in store, I note that Dr. T. Watts Eden has lately told us that "in the United States an important group of younger obstetricians are advocating and practising induction of labour in all cases before term, to save the patient from the discomfort of the last few weeks of pregnancy, and that it is being done in our own country also to some extent."¹

The birth of the child will be duly notified and the mother fully instructed on the subject of breast-feeding before she leaves hospital. She will then be referred to the infant clinic or welfare centre, to which she will be required to take the infant every week, so that he may be weighed, his progress carefully watched, and his feeding superintended until he reaches school age and is handed over to the school medical officer. If any definite medical or surgical treatment should in the meantime be necessary he will be transferred to a treatment clinic.

THE PROBLEM OF POPULATION.

And now let us turn aside for a moment from the newly-born infant to consider a question on which the parents will rightly expect definite guidance, if not authoritative command, from the State—viz., what period should elapse before they again venture upon the responsibilities of parenthood and also how many children will it be advisable for them to beget. If any definite limits are fixed, advice will naturally be asked as to the best method of preventing a premature or a superfluous pregnancy. There are still some members of the community, few, indeed, I think in the medical profession, who do not recognise any limit as desirable to the number of a family and consider it a duty for parents to obey the ancient command, given under conditions very different from those of the present day, to be fruitful and multiply and have as many children as possible. They argue that a tenth or twelfth child may be a genius—a Shakespeare, Newton, or Pasteur, and that restriction of the family may thus involve a world loss.

Such good people, however little they may intend it, are the most zealous supporters of war, for are not most wars really due to the pressure of an increasing population? By providing an unlimited number of children they are doing their utmost to supply also unlimited "cannon-fodder." As medical science progressively lowers the death-rate and limits the extension of epidemics, whilst improvements in methods of transport steadily diminish the risks of localised famines, it is difficult to see any way by which the natural increase of population can be kept

from outgrowing the food-producing resources of the earth except by ever increasingly destructive wars. It is true there are still large areas in Siberia, America, and Australia very sparsely populated, but should the inhabitants of the world continue to multiply at the rate at which they have done during the last century, these vacant spaces would be filled within an appreciable time. As Dean Inge observes, "Over-population is the result of a very low standard of civilisation. Families are restricted whenever the parents have social ambitions and a standard of comfort."

It may, of course, be argued that if we fail steadily to increase our numbers, more prolific races will gradually displace those which are more or less stationary, so that presumably in course of time Germans will submerge French and English, Russians will conquer Germans, and Chinese overrun Russia. What an appalling prospect for the unfortunate human race—to be compelled to multiply as rapidly as possible, and then to have to choose between starvation and recurring, sanguinary wars! An objection may naturally be raised that if birth restriction were practised extensively the population might actually begin to decline, or at any rate cease to increase materially, so that emigrants would no longer be available to fill up the vacant lands in our colonies. This danger, however, could easily be met by a careful system of taxation. If after a certain number of years of married life parents had failed to produce, say, three or four children, and no adequate reason, either of health or finance, for the deficiency were forthcoming, heavy extra taxation could be imposed for each child under the minimum. It is interesting to note that in Vienna, a few months ago, owing to economic conditions, definite steps were being taken by the wage-earners' sick-clubs, in active coöperation with the gynaecologists, to encourage the prevention of conception amongst women whose circumstances, after investigation by competent persons, justified their wish not to have children.²

BIRTH CONTROL: A LEAD FROM THE MEDICAL PROFESSION.

Assuming, as I think we justifiably may, that, in the future Utopia birth restriction will not only be practised but encouraged, what directions will the medical profession give for the prevention of conception? Nature has provided so carefully for the all-essential factor of the propagation of the race, that possibly no method of restriction can be devised which will be absolutely free from drawbacks or disadvantages of one kind or another, whether of possible damage to health or of diminution of pleasure. Such conceivable drawbacks, however, can be hardly comparable to the evil results, at least in town life, of families of unlimited size. Some people assert that the only safe and right plan is absolute continence so long as pregnancy is not desired; they are usually either elderly folk who have probably forgotten that they ever had sex instincts, or worthy ladies who perhaps never developed them, or ecclesiastically-minded celibates who are apparently anxious to make a vicarious atonement for their own infertility by encouraging the highest possible fecundity in others. Anyhow, the suggestion that healthy young people should live together in the close association of happy married life, and yet consummate the marriage only at rare intervals, is hardly worthy of serious consideration, unless it be with the doubtless highly laudable but perhaps unnecessary object of providing work for unemployed psycho-therapists.

I do not propose to discuss other and more practicable methods of birth restriction, but will merely make one suggestion: from the average size of doctors' families one would infer that most of them practise some form of restriction, therefore, let all married medical men and medical women be invited to state, under the seal of strict anonymity, what method they employ. The replies would certainly be interesting and probably instructive.

THE DOOMED APPENDIX.

Let us return from this digression to the life-history of our infant. Before he reaches school age several most important points will have to be considered: first and foremost, what superfluous parts or organs is it desirable to remove?³ If he is a boy it goes without saying that he will be circumcised in early infancy. A far more serious question, however, will arise a little later in both sexes—viz., should the appendix be removed as a matter of routine? When we remember that even now, despite all improvements in diagnosis and treatment, appendicitis is responsible for about 2500 deaths a year in England and Wales, a number which tends to increase rather than to diminish; when we reflect on the enormous amount of illness and suffering to which it gives rise in the thousands of cases which recover; when we know that the abdomen is rarely explored by any surgeon without the appendix being removed; when we realise how rarely the surgeon seems able to assert wholeheartedly and conscientiously that any appendix which he sees lurking life is really absolutely healthy, and when we find that no one apparently is ever the worse for its removal, is not the conviction irresistibly forced upon us that it would be infinitely preferable in all cases to remove it in early childhood, and so save thousands of lives and an absolutely incalculable amount of disease and anxiety? The mortality from such an operation, performed by surgeons who by constant practice had attained the highest perfection of technical skill, would be almost negligible.

ADVISABILITY OF UNIVERSAL COLECTOMY.

Should we, however, in the future be content to stop here? If preventive removal of the appendix was so much to recommend it, ought we not to consider the enormous diminution of disease and the great prolongation of life which should result from complete removal of the entire colon? Let us think over and weigh carefully the reasons for advising a step apparently so drastic. We have the highest surgical and other authority for stating that, owing to man's most unfortunate assumption of the erect posture, his large intestine tends to become one prolonged cess-pool, at any rate in a vast proportion of civilised humanity; that this intestinal stasis leads to the reduction of poisons and so to a chronic toxæmia which gives rise to degenerative changes in every tissue and organ of the body; and further, that owing to this auto-intoxication, many grave diseases, due to invasion of the body by micro-organisms, are prone to develop, which would not occur were the vitality of the tissues maintained at a normal level.

A Few Results of Chronic Intestinal Stasis.

Let us briefly note the actual morbid conditions and diseases which, in one or other of the above-mentioned ways, may, it is asserted, be produced as a result of chronic intestinal stasis. In the alimentary canal itself are pyorrhœa, all kinds of indigestion, ulcer, and finally cancer of the stomach. Incidentally, as a physician, I should like to take this opportunity of saying how much indebted I am to those surgeons who have pointed out the direct connexion between simple ulcer and malignant disease of the stomach, a connexion which physicians themselves might easily have missed, especially as it does not extend to duodenal ulcer. With deep regret I observed some months ago that Sir Bernard Spilsbury⁴ had ventured to make the almost blasphemous suggestion that microscopic appearances which really were due merely to regenerative changes in the margin of a simple cancer had actually been mistaken for those of commencing malignant disease. A suggestion which made me recall with a shudder that remarkable saline-fibroid formation in the arterioles, described

many years ago by Gull and Sutton, upon which most important conclusions were based, until it was shown that the hyaline appearance was due to the action of the acidulated glycerine in which the preparations were placed for examination. Returning now to changes in the intestine from intestinal stasis, we may enumerate duodenal ulcer, appendicitis, all forms of colitis, diverticulitis, volvulus, and finally malignant disease of the large intestine; also, of course, visceroptosis. Furthermore, it is the opinion of certain experts in tropical diseases that dysentery only becomes chronic in those affected by intestinal stasis, and it has been demonstrated that chronic amoebic dysentery can be frequently cured by relieving the latter.⁵ From the intestine infection may extend to the pancreas, leading to induration, inflammation, cancer, and diabetes; to the gall-bladder, giving rise to gall-stones and cancer, and to the liver, producing many diseases of that organ.

Turning to other parts of the body we find chronic intestinal stasis regarded as a cause of adenoids and enlargement of the tonsils, these often being followed by infection of the cervical glands; of exophthalmic goitre and other diseases of the thyroid gland, including atrophy, cystic disease, and cancer, also of Raynaud's disease and of typical asthmatic symptoms. In the kidneys it is said to lead to bacilluria and to inflammatory or degenerative changes; in the ovary to cystic disease; in the uterus to retroversion, to metritis or endometritis, and to cancer (in fact, it has been said, "If woman were not imperfectly drained the gynaecologist would not have been evolved"); in the vascular system to either increase or decrease of blood pressure, in the former case with atheromatous changes in the aorta, and all the various evils to which this in turn may give rise; high blood pressure with enlarged heart occurring mainly in men, low blood pressure and flabby heart particularly in women. In the nervous system there are described various forms of so-called "neuritis," sciatica, &c., headaches, sleepiness or sleeplessness, melancholia—culminating in suicide—or imbecility. The muscles waste and become flabby, so that round shoulders, lateral curvature of the spine, flat-foot, and knock-knee are apt to develop. Indurative changes in the breasts may go on to cystic or other forms of degeneration and eventually to malignant disease. There is loss of fat, and consequently marked alterations in the form and contour of the body, especially of women. The skin becomes pigmented, is very liable to pustules, and excretes an offensive sweat. The hair of the head is apt to fall off, and that on the cheeks, lips, and chin to develop to excess. A serious loss of accommodative power in the eyes is stated to develop, so that presbyopia is greatly hastened and the ciliary muscle weakened.

Coming finally to general infections, we are assured that "the presence of tubercle, except by direct inoculation, is . . . always preceded by that of auto-intoxication." This seems to be especially true of tubercle of the intestine and mesenteric glands; Addison's disease may likewise develop. Also rheumatoid arthritis (including Still's disease), like tubercle, is said never to be present except in association with auto-intoxication due to chronic intestinal stasis.

The Remedy.

Incomplete though this list may be, it is a truly appalling catalogue of the possible, or even probable, effects of this most grave, distressing, and common condition, worse even than the evils which a few years ago were attributed to uric acid, now regarded as but a harmless by-product of metabolism; such are the vagaries of professional fashion. It might well seem a simpler and shorter procedure to enumerate the diseases which are not due to intestinal toxæmia, but that, as knowledge increases, it may become increasingly difficult to say of almost any morbid condition that it cannot be produced in this way, either directly or indirectly. Anyhow the case against an organ

³ It may be desirable at this point to say that the writer hardly expects or desires all his subsequent arguments and conclusions to be taken altogether literally.

⁴ Proceedings of the Royal Society of Medicine, Section of Medicine, October, 1922, p. 25.

⁵ THE LANCET, 1922, ii., 1116.

which is apparently responsible for so many of the most serious and fatal disorders to which man is liable, becomes overwhelmingly strong. We may, however, fairly ask if there is anything to be said on behalf of the large bowel; any good reason for its existence; any mitigating or extenuating circumstances to set against the long indictment of its infamies and iniquities. Apparently there is not. In 1903 Metchnikoff wrote: "It is no longer rash to say that not only the rudimentary appendix and the cæcum, but the whole of the large intestine are superfluous, and that their removal would be attended with happy results." In 1902 Dr. Barclay Smith, of Cambridge, said: "The statement is perhaps a bold one, but I am convinced that the large intestine is practically a useless incumbrance to man." Finally, in 1912 we have the words of Sir Arthur Keith: "Every year the opinion gains ground that the great bowel, from appendix to rectum, has become, so far as man is concerned, a useless and dangerous structure." Not so many years previously the same statement might well have been made of the thyroid gland; at any rate, whether made or not, the idea was acted upon, with quite remarkable and instructive results. Of the thyroid it was urged that at least it added something to the external beauty of the human form, but even this poor excuse cannot be made on behalf of the colon. Can anything more opprobrious and degrading be said of it than to be compelled to call it a cesspool! Surely the case is complete for routine removal of this cesspool in any community which regards health as the first essential of happiness. Doubtless for a time there would be a certain percentage of casualties, but this would naturally diminish as a race of surgeons arose absolutely expert in performing colectomy, and the number of deaths from the operation would indeed have to be large to out-balance the enormous gain to mankind from the abolition of only a few of the maladies which have been attributed to intestinal toxæmia; picture, if we can, a world in which there were no diseases of the large intestine or appendix, no tubercle, no rheumatoid arthritis, and certainly an immense reduction in the cases of malignant disease. The late Sir Henry Thompson in one of his lectures on Diseases of the Male Genito-Urinary Organs observed that man paid a high price for his distinctive organ; with yet greater truth we may say that men and women alike pay a far higher price for the distinctive erect posture they have so presumptuously assumed.

Importance of a Supply of Oil.

At what age, by preference, colectomy should be performed I will not venture to suggest, but as some of the most important of the lesions to which stasis is said to give rise begin quite early in life—for instance, adenoids, enlarged tonsils, and abdominal tuberculosis—it is evident there should be no unnecessary delay in eliminating their cause, and Sir Arbuthnot Lane tells us he has performed colectomy with complete success very early in childhood.⁶ For conscientious objectors, or until the operation became thoroughly popularised, the public health authorities would probably enjoin the liberal use of paraffin, and in the long run it would obviously be a really economical procedure to distribute it to the population generally at the public expense. The immense hygienic importance of an absolutely unlimited supply of this invaluable remedy should, therefore, be remembered whenever the question arises of giving up our hold on the Mesopotamian oil wells.

ADVISABILITY OF UNIVERSAL TONSILLECTOMY.

In considering what further parts of the body it may be desirable to remove we come next to the tonsils and, of course, any adenoidal overgrowths with which they may be associated. We are, however, confronted with the difficulty that, as has already been suggested, a colectomy in early life might suffice to prevent any subsequent development of throat trouble. Experience alone can decide this, but in

view of the possibility that this operation might not become universal for a considerable time, or might not be performed soon enough to avert a condition which sometimes develops in the first few months of life, it is quite likely that tonsillectomy would be compulsory in a well-ordered state.

In the case of the colon it seemed desirable to call attention to the long list of diseases for which its presence is responsible, because the enormous variety and the universality of these evils is perhaps even yet not sufficiently recognised, but it is quite unnecessary to dilate upon the many troubles, local and general which result from adenoids and enlarged tonsils; they are fully known to us all. The actual question which confronts us is whether, under present-day conditions the tonsils are ever really healthy. I am bound to say, judging especially from what I learn from some of those who specialise in that department of the body, it seems so rare for anyone to have healthy tonsils that, for all practical purposes, everyone would be better without them. Their removal always seems to be indicated, usually at once, occasionally at the first convenient season. In former days the teaching as to the training of a boy was—"flog him when you meet him, for if he is not naughty now he will be very soon," so of the tonsils it may be said it is better to remove them forthwith, for if they are not diseased now they will be presently. Prevention is surely better than cure, and it is hardly possible to imagine the extraordinary gains which would follow these most unnecessary and disease-producing organs were always removed at an early age, the great improvement both in physical and in mental development, the absence of diseased cervical glands and all their consequences, the diminution in deafness and in ear diseases generally, in laryngitis, bronchitis, and other lung troubles, in gastro-intestinal disturbances, in many grave bacterial infections, not to mention the possibly lessened incidence of abnormal conditions in more distant parts of the body, resulting from some mysterious reflex effect of the unhealthy state of the naso-pharynx. It is possible that the frequency of rheumatic fever, with all its disastrous consequences to the heart in childhood, would be greatly lessened although I am obliged sorrowfully to confess, from considerable personal experience, that the most complete removal of tonsils and adenoids does not suffice to prevent recurrent attacks of rheumatism in children. Perhaps this merely provides another argument for prophylactic removal of the tonsils during the first two or three years of life, before any rheumatic manifestations have developed.

Doubtless in the model state of the future tonsillectomy would not be done under the present somewhat haphazard conditions, but in municipal hospitals into which children would be admitted in successive batches and in which they would be kept until their raw surfaces had begun to heal, so that certain undesirable results, of which we occasionally hear, would no longer be possible.

THE CASE FOR FALSE TEETH.

The next problem which the medical rulers of the hygienic state would have to consider would be that of the teeth. Again, as in the case of the tonsils, we have to face the possibility that removal of the "cesspool" would so far diminish the vulnerability of the teeth and gums to microbial infection that oral sepsis would become comparatively rare, and thus the standard set by Moses, as described in the Vulgate version of Deuteronomy, to which attention has recently been drawn by Mr. R. C. Ackland, President of the Section of Odontology of the Royal Society of Medicine, would be commonly reached; "Moses was 120 years old when he died; his eye was not dimmed, nor were his teeth loosened." Unfortunately, however, there are still many authorities who will accept intestinal stasis as an important factor in the production of pyorrhœa, some even who pervert the reverse the order of events and maintain that oral sepsis is a frequent cause of intestinal infection.

⁶ THE LANCET, 1922, ii., 1116.

Obviously on this point a fight to a finish is desirable, unless, indeed, as so commonly happens, each party has a certain amount of truth on its side, although, of course, it would be entirely contrary to human nature (scientific or otherwise) for the disputants in any quarrel to admit so disconcerting a fact. Anyhow I fear for the present we had better assume that colectomy might not solve the problem of the teeth. The difficulty, then, is aggravated by the fact that we have to deal with two sets of teeth. Those of the first dentition are, however, got rid of so soon that their diseases can be treated with comparative ease. It is with the second set that serious trouble begins, and the disorders and diseases attributed at the present time, on the strongest evidence, to oral sepsis, and especially to peri-apical bone necrosis secondary to dental caries, are almost as numerous and fully as varied and serious as those supposed to be due to intestinal stasis, in fact, to a considerable extent the two overlap. The result is that it is not easy for an unprejudiced and unbiased observer to decide whether man is more to be pitied for his misfortune in having inherited from his remote ancestors teeth or a large intestine. Without them both it would appear that he might have a reasonable expectancy of attaining a patriarchal age. One of the great questions of the future, therefore, must be whether it would not be far better to extract the second teeth at or soon after their first appearance, rather than have to remove them one by one at irregular intervals later on, or possibly simultaneously at one fell swoop, after they have given rise to an infinite amount of local discomfort or actual suffering, and, what is far more important, to infective conditions of other parts of the body, which before their cause is removed, may materially shorten life or at least produce permanent and crippling deformities. The question is really precisely similar to that of removal of the colon, whether prevention is not better than cure, whether, in fact, the comparatively slight discomfort of having to wear artificial teeth just a few years earlier than would otherwise be the case, would not more than be atoned for by an escape once and for all from the ever-increasing risks and penalties involved in trying to retain the permanent teeth (falsely so-called) for a few fleeting years.

There is, moreover, the added incentive that removal of the teeth involves practically no risk to life, whereas this can hardly be said at present of colectomy. If our dentists could find some way of preventing premature dental decay and oral sepsis the matter would, of course, be entirely different, but for the moment at any rate this discovery seems to be as far off as that of the cause of cancer. If the teeth are allowed to remain the great danger is that all unsuspectingly they may give rise to grave septic conditions; in fact, thousands of people to-day are, as has been truly observed, almost certainly nourishing a viper in their bosom. We know only too well that external appearances may be entirely misleading, that the teeth may look perfectly healthy, that all the outward indications of pyorrhoea may be conspicuous by their absence, yet that at their roots grave changes may be in progress, which constitute an ever-present menace to health and even to life, and that when this hidden source of disease is discovered the unhappy patient may hesitate too long before consenting to part with apparently healthy teeth.

It is now well known that no teeth can be pronounced sound until they have been subjected to a complete radiological examination. I wonder how many people there are, nearing middle age and with any considerable number of teeth left, who could pass successfully so severe an ordeal. It would certainly be intensely interesting if reports could be obtained of the condition of all the patients who in recent years have been rendered edentulous under medical or dental advice, as to the exact amount of benefit they have derived from the treatment. One meets now and then with ingrateful patients who persistently avow that their rheumatism, their pains, their nervous or intestinal symptoms are not one whit the better since the

complete removal of their teeth; occasionally they obstinately maintain they are not so well, at times even they tend to pass into chronic invalidism and spend their days, like Augustus mourning his lost legions, in unavailing lamentations over their lost members. Clearly they are the victims of our present haphazard system or want of system, whereby we are only too often content to await the full development of disease, instead of intelligently trying to prevent its onset. Doubtless before these patients were advised to have extraction performed, or at any rate before they reluctantly consented to its being done, under the scientifically combined pressure of family doctor, consultant, dentist, and radiologist, pathogenic germs had penetrated deeply into the tissues around the dental sockets, and, even if these had been well scraped out, an intractable infection had already occurred in the intestine, joints, or other distant parts. No, the case in favour of preventive extraction seems complete; the alternative of having the teeth of the whole adult population examined at least once a year, not only by a dentist but also by a radiologist, is hardly practicable, even in the most highly organised medical state. How much simpler and in every way better to prevent, by extraction of the teeth in early adult life, all the prolonged sufferings, the varied risks, and the grave perils which will be involved should the removal be postponed until it becomes obligatory in middle life, when perhaps irreparable mischief has already been done.

Time does not permit us to pursue further the fascinating problem as to what other parts of the body it might be desirable to remove, except just to mention the valuable suggestion that in women after the climacteric the uterus should be excised to abolish the risk of cancer in that organ, with a consequent saving of some 4000 lives a year in England and Wales; an equal saving of life from mammary cancer might also be effected by removal of the breasts about the same time. In elderly men the prostate would be removed as soon as there were any accumulation beyond a very few drachms of residual urine in the bladder. After all the removal of an organ nowadays need hardly be regarded as a serious matter, seeing how easily any resultant defects can be remedied by organo-therapy.

VACCINE TREATMENT.

We reach next the important question against what diseases should the child as he grows up be vaccinated? We may take for granted here vaccination against small-pox, always bearing in mind, however, that to secure complete immunity it will probably be necessary to repeat the operation at intervals of not less than ten years throughout life. A far more important matter is the desirability of systematic vaccination against the great group of the infective diseases of the respiratory passages—the common cold, laryngitis, bronchitis, broncho-pneumonia, acute pneumonia, and influenza. We must recollect that, so far as this country is concerned, we have in this group the most frequent of all diseases—the common cold—itsself relatively trivial, yet responsible for an enormous amount of inconvenience, discomfort, and temporary invalidism, and often giving rise to such serious conditions as middle-ear and sinus troubles, bronchitis, &c. It includes, also, two of the most fatal of all diseases in temperate climates—bronchitis and pneumonia—rivalled or surpassed only by cancer and phthisis, and it embraces also influenza, from time to time the most widespread and fatal infective disease. Could we abolish the deaths from this great group of diseases, the mortality rate in this country would be reduced by over 15 per cent. and by much more in those years in which influenza, but for preventive inoculation, would be epidemic. Judging from what we are told by the protagonists of vaccination, is it not reasonable to expect that in the future, given a sufficiently obedient population, these common and most fatal diseases may be brought under control by a well-devised blend of some half-dozen micro-

organisms—pneumococci, streptococci, *Micrococcus catarrhalis*, influenza bacilli, &c.—used as a vaccine, whereby immunity would be produced? As these diseases spare neither age nor sex, and are no respecters of social position, it follows that the use of the vaccine must be started in early infancy, must be continued throughout life, and its beneficent influence extended to the whole population; in other words, the prophylaxis must be carried out on thoroughly democratic lines. At what intervals the injections should be repeated I will not presume to say, certainly every few months at least, but probably more frequently. I see it stated of one anti-catarrh vaccine that three graduated doses should be given at intervals of seven days during the autumn, and for those who are very susceptible to colds or catarrhal conditions during the winter months a subsequent dose each month during that period. One of the incidental advantages, therefore, of the universal adoption of this preventive treatment is that it would at least do something towards solving the problem of unemployment. If the inoculations were started early in life, before pathogenic germs had already obtained a lodgment in the respiratory passages, the risk of any untoward sequel would presumably be negligible. From time to time one hears rumours that patients have become seriously ill with acute respiratory disease after, apparently even as a result of, the use of an anti-catarrh vaccine. Since, however, I know of no published record of any such unfortunate happening I can only conclude that these stories must be malicious inventions. It is so desirable, nay essential, that we should be informed of any undesirable results from new methods of treatment, whether preventive or curative, that it is obvious any practitioner meeting with such consequences would at once make them known.

We may no doubt anticipate that in course of time preventive vaccine treatment will become available for all serious infective diseases—measles, whooping-cough, scarlet fever, diphtheria and (most important of all) rheumatic fever—just as it is already available for the prevention of the typhoid group of diseases whenever required owing to the withdrawal or absence of those hygienic precautions which normally suffice to prevent their occurrence. It is to be hoped that a separate vaccination at short intervals, against each disease, would not be essential.

THE CARE OF EYESIGHT.

At the commencement of school life the eyesight of every child would, I need hardly say, be most carefully tested. We are just beginning to appreciate the extremely important symptoms, especially in connexion with the nervous system, which may arise from slight errors of refraction, errors which the child exhausts his nervous energy in trying to overcome, whereas were the lesion more gross the attempt at accommodation would not be made. It is becoming evident, if we are to trust some of our ophthalmologists, that all such defects, whether they give rise to obvious symptoms or not, should be corrected up to one-eighth of a diopter, and really it is not easy to see why the line should be drawn at that. Obviously, again, unemployment will benefit by the increasing demand for spectacles, for it would seem that a really perfect pair of eyes must be almost as exceptional as an absolutely sound set of teeth.

PSYCHOTHERAPY.

As the child grows older the question of psychotherapy will naturally arise. It would clearly be most unsatisfactory to free the body, at a considerable expenditure of time, trouble, and even discomfort or risk, from some of the many ills to which flesh is heir, and yet leave the mind a prey to all the neuroses and psychoses which at present so sorely afflict it, and to ignore the absolutely incalculable amount of misery, of domestic unhappiness, the blighting of promising careers, and the waste of life's opportunities to which mental disorders give rise. Fortunately the outlook

is a hopeful one, for what colectomy, tonsillectomy, tooth extraction, and divers forms of vaccination may be expected to do for our bodies, psychotherapy and the investigation of the unconscious mind promise to do for our minds. When we think of the amount of time spent in the treatment of patients we label as suffering from mental debility, nervous overstrain, hysteria, neurasthenia, psychasthenia, anxiety states, obsessions, phobias, stammering, and more serious conditions, the imagination hardly enables us to picture a universe in which they would all either be prevented or rapidly cured. We seem to be entering a new world of hope and promise when once we realise that by the discovery of a single simple word which excites some emotional reaction, or by the correct interpretation of a dream, a phenomenon hitherto regarded as too trivial to be worth consideration, we are able to unearth old experiences from the subconscious mind, and by bringing them to the surface start a process, which will lead to the complete release of the patient from fetters which for years may have hampered his activities or even completely crippled his usefulness.

How marvellous, for instance, to discover, owing to a patient getting blocked on the simple word "long," that all her troubles were due to her "longing" for a certain young man, whose offer of marriage she had rejected in haste, afterwards repenting at leisure of her refusal! How instructive to learn that a small schoolgirl's propensity for stealing pencils was stopped as a result of the discovery that a pencil symbolised to her the penis of her young brother, and that her youthful mind had been filled with envy and jealousy when she discovered that he possessed an organ of which she was devoid! What new hopes of successful treatment are raised when we read that a young man who had been stammering for several years was perfectly cured of his infirmity when he realised that his difficulty in articulation was worst for words commencing with "K," and that this was the first letter of the name of a former sweetheart who had jilted him in favour of another man! What therapeutic possibilities await us when we really understand that a woman's dream of being run over symbolised her desire for sexual intercourse—for is not a dream the disguised fulfilment of a repressed wish?—and that such apparently prosaic dreams as of walking up and down stairs, flying, or journeying in a train or other vehicle, are to be similarly interpreted! Doubtless in the future psychoanalysts will be attached not only to all our schools, colleges, and universities, but also to our Courts of Justice; in fact, the whole administration of Justice will be profoundly revolutionised as soon as systematic efforts are made to probe the unconscious minds of our criminals and so arrive at a more accurate estimate than is possible at present of their degree of responsibility. A very large number of men and women will have to be selected and trained as modern Josephs and Daniels, up-to-date successors of the magicians, the astrologers, the Chaldeans and the soothsayers who flourished at the court of ancient Babylon, specialists in the admittedly difficult task of the interpretation of dreams, for "not everyone can become an interpreter of dreams. It takes a skilled and patient specialist thoroughly to understand the process."

When we read that Freud has spent three years on a single difficult case of psycho-analysis, and that very frequently the analysis drags out through weeks or months, we realise what an immense number of practitioners will be required adequately to deal of these lines with the prevention and cure of all the disorders and functional diseases of the nervous system. Truly we need be under no apprehension as regard to any diminution in the demand for medical men in the coming Utopia, only they will be distributed differently than they are at present; the vast majority will presumably be either surgeons, radiologists, psychotherapists, or pathologists, with, of course, a large number of dentists to cope with the necessary extractions and the manufacture of artificial dentures.

TUBERCULOSIS.

Time will not permit any discussion of the methods which will be employed in the future for the prevention and cure of tuberculous disease, should it not be eradicated by the universal adoption of a timely colectomy. Two at least of our present customs, it is to be hoped, will be altered. The first is that of sending patients suffering from phthisis into sanatoriums, admirably and expensively equipped, keeping them for about three months and then letting them return to attempt to earn a living in the same conditions and amid the same surroundings as those under which they first contracted the disease. What reasonable probability is there that a man who in a particular environment has developed phthisis, will not relapse when, with lungs more or less extensively damaged, he returns to his old conditions of life, with diminished wage-earning capacity and consequently a severe handicap in the struggle for good food and good housing? The problem presented by the chronic or temporarily healed consumptive is far more than a medical one, it raises questions of the widest social interest and importance.

The other change we may look forward to is in our present practice of doing our best to develop tuberculous disease in children by allowing them to drink milk containing an unknown number of tubercle bacilli, and then when the result which might be anticipated actually follows, going to infinite trouble and expense to prolong the lives of these same children after they have been crippled, deformed, maimed, and scarred by tuberculous disease of bones, joints, or glands. Even if we cannot as yet entirely prevent the presence of tubercle bacilli in cow's milk, we can at least effectively destroy them by the simple measures of boiling or pasteurisation. A vast amount of progress will have to be made in our medical Utopia in connexion with the purification of the national milk-supply.

VENEREAL DISEASE.

On leaving school every member of the community will be transferred from the school doctor to the panel practitioner, so that continuity of medical supervision may be maintained. About this time the very serious question will arise as to what steps should be taken to prevent the young men, after they reach the age of puberty, from contracting venereal disease. Each one will receive full instruction with regard to his sex organs, their functions, use and abuse. He will be told that it is his duty to remain continent until such time as he is able to marry and that continence is the only absolutely reliable safeguard against infection. He will also be informed, however, that if he finds himself unable to follow these counsels of perfection, that at any time his natural impulses prove too strong or his self-control, it will be his duty to use certain chemical methods of prophylaxis, in regard to which he will receive detailed and minute instructions, and these personal admonitions will be reinforced from time to time by an intensive propaganda carried on throughout the urinals of the country. Necessarily there will be difficulties, which, however, should serve merely to stimulate the enthusiasm of those who have to overcome them. For obvious reasons it will be desirable for all young men always to have the disinfectants with them, just in the same routine way that we hope they would carry a pocket handkerchief; otherwise, sooner or later they will be wanting at the critical moment, and it is at least conceivable that their absence might not serve as an adequate deterrent to illicit intercourse. In a really well-drilled and well-trained community, fully instructed on the importance of health compared with mere freedom, the police might be authorised to demand from all unmarried men, at any rate after a certain hour daily, the production of their prophylactic packets, with punishment by fine or imprisonment of those failing to produce them. Until this ideal level of social hygiene had been attained, it might suffice—as these diseases would of course be strictly notifiable—to punish severely any man suffering from one of them

who could not prove that he had used the recognised methods of disinfection.

The use of alcoholic beverages would likewise become a matter of the utmost importance; if it were recognised that they tended to increase the frequency of promiscuous sexual intercourse and also, if the quantity taken were at all excessive, gravely to interfere with the prompt and efficient use of prophylactic remedies afterwards, the health authorities might find it necessary to follow the example of the United States and enforce complete prohibition. Again, a well-disciplined, well-instructed and docile population would undoubtedly welcome such a loss of personal freedom in the interest of the health of the community. I will not pause to discuss the interesting question as to what period of time would be likely to elapse before the entire nation, from the highest to the lowest, in overcrowded town and remote rural district alike, had been trained to carry out efficiently these precautions under all circumstances and conditions, but let us consider for a moment the really remarkable results which would have been achieved should venereal diseases thus be reduced to an almost negligible quantity.

Ever since the earliest beginnings of man's history probably one of his highest ambitions has been to be able to do wrong without suffering any evil consequences; hitherto his efforts have not been rewarded with any conspicuous measure of success, so much so that men have actually been taught that wrongdoing (what old-fashioned people called sin) would not go unpunished and that what a man had sown that he would also reap. Now at last arises a hope for mankind of release from this bondage, for if in one important department of life men may be enabled to transgress with a reasonable assurance of impunity, why may not relief come equally in other directions? Nor is this by any means the end of the wonderful vista which opens before us. Hitherto in nearly every form of wrongdoing not only has the individual offender often been punished, but other and perfectly innocent people have generally suffered also. The lamentable consequences of venereal diseases to innocent women and children constitute in fact one of the strongest arguments in favour of the use of prophylactic measures, but it would perhaps be difficult to find any form of evil in which other people may not suffer as much as and not uncommonly more than the offenders themselves. We have only to think of the far-reaching consequences of drunkenness, gambling, &c. In society as constituted it must be so, for as civilisation becomes more and more complex, so it becomes increasingly true that "no man liveth to himself," and the knowledge that this is so may be reckoned as one of the deterrent influences against evil-doing. A man may be prepared to "damn the consequences" so far as he himself is concerned, and yet be less reckless when the interests, the happiness, perhaps the lives of others, are also involved. Now, however, there opens before us the prospect, in at any rate one most important department of morality, of men being able to do wrong with a minimum of physical risk either to themselves or to any one else. It is as if some way were discovered, perhaps it will be, whereby, for instance, men should be enabled to take excessive quantities of alcohol, with all the enjoyment thereof, and yet wholly without any immediate disagreeable after-effects, either physical or mental: or as if they could recklessly indulge in all the excitements of gambling with a tolerably certain assurance of immunity from financial loss. The outlook is, indeed, far-reaching, and yet law has a disconcerting way of asserting itself, and it is perhaps premature to state dogmatically that one of man's greatest ambitions has been attained and that the old statement "Whatsoever a man soweth, that shall he also reap" has been finally rendered obsolete.

May we not, however, go a step further? It has been suggested that the abolition of venereal disease would actually improve morality by placing it on a higher plane, for if there were no risk of unpleasant consequences all the continent people would obviously

be acting from really high motives and not possibly from low and selfish ones only. It is said, for instance, and there is doubtless much truth in the statement, that a morality which depends only upon fear is not worth a great deal; that the man who abstains from promiscuous sexual intercourse merely because he is afraid of possibly contracting venereal disease, is after all a poor creature, hardly worthy of comparison with his more adventurous brother, who is boldly prepared to take risks. I am not sure that we should care for the logical development of this argument in other departments of life. We should probably prefer that a potential thief or burglar, should be deterred by the possibility of imprisonment, if no higher or better deterrent were available. We have at present hardly reached the stage when we should put the brave and adventurous thief, who boldly takes all risks, possibly even the danger, if he be an armed burglar, of being tried for his life, on a pinnacle of moral pre-eminence over the man who remains honest solely because, like the proverbial Scotsman who had tried both honesty and dishonesty, he has come to the conclusion that the former is the best policy, and is such a coward that he dare not incur the chance of disagreeable results.

The Dangers of Continence.

But the possible gains to mankind do not even end here. We used to be taught that self-control, self-restraint, &c., were virtues to be cultivated and encouraged, that they strengthened and built up character and so on, but is this really so? In the light of modern knowledge is it not rather a fact that self-repression, especially sex repression, may give rise to a great variety of nervous disorders and be responsible for a vast amount of illness and inefficiency? The benefits conferred by prophylactic packets are likely to be not merely negative, in protecting guilty and innocent parties alike from the dangers of promiscuous sexual intercourse, but also positive, by preventing all the evil consequences of repressed emotional instincts to which continent people are apparently liable if they do not succeed in completely sublimating their sex energy. Truly, if venereal prophylaxis attains the success hoped for by its sanguine advocates, it will lead to far-reaching consequences, more far-reaching perhaps than even its most enthusiastic supporters anticipate. With such wonderful potentialities for good, might not calomel and Condy's fluid, in an earlier stage of the world's history, have been justly worshipped in the temples of the gods as agents of almost untold benefits to suffering humanity?

ORGANOTHERAPY.

It may well seem that as a result of a scientific system of eugenics, of the elimination of intestinal stasis, of oral sepsis, and of tonsillar infections, with efficient prophylaxis of venereal disease, the almost complete extinction of tuberculous lesions, the effective control of the catarrhal diseases of the respiratory passages and of most of the common infectious diseases by a well-considered and thoroughly systematised plan of universal vaccinations, and, lastly, with the prevention or speedy cure of the functional diseases and disorders of the nervous system by skilful psycho-therapy, that comparatively few illnesses will be left prematurely to terminate man's existence, and that Metchnikoff's ideal will be attained (although, unfortunately, he himself failed to reach it) that, apart from congenital disease, poisoning, accident, and suicide, man will in nearly all cases die from a true senile decay. There remains, however, the possibility of premature degenerative changes in different tissues or organs, due partly to hereditary tendencies and partly to excessive strain unwisely thrown in earlier life upon special parts of the body. Now, therefore, as the final and crowning step in the prevention of disease and the prolongation of life we come to the part which in the future will be played by organo-therapy. The discovery of the functions of the thyroid and that those functions, after destruction of the organ itself, can be carried on satisfactorily by

preparations of the gland given by the mouth, has opened up vast prospects for the future which at present we are only beginning to envisage. The list of diseases which it is stated may be benefited by thyroid medication is a very long one; I will not attempt to enumerate them, but as a result of the remarkable success which attends its use, in certain morbid conditions, preparations have been made from nearly all the organs and tissues of the body, including the parathyroid, thymus, pituitary (anterior and posterior lobes), pineal gland, brain, spinal cord, sympathetic nerve ganglia, parotid, stomach, duodenum, small intestine, liver, pancreas, kidney, suprarenal, spleen, lung (as an indirect preventive against pulmonary tuberculosis in the young), testicle, prostate, ovary, corpus luteum, mammary gland, placenta, lymphatic glands, bone marrow, and red blood corpuscles. Each one of these is said to be definitely indicated in the treatment of a varying number of more or less diverse morbid conditions, functional or organic, serious or slight. In addition Prof. Swale Vincent tells us that heart disease has been treated by extracts from heart muscle, iritis by the subcutaneous injection of extracts of the ciliary bodies, and diseases of the joints by extracts of synovial membrane.⁷ We are, however, fast passing beyond the primitive idea of administering one of these organic preparations alone; we are learning the moral of the old story of the belly and its members, and are beginning duly to appreciate the fact that when one member, and especially one gland, suffers, all the members and glands suffer with it. The realisation of this introduces us to polyglandular therapy, with its enchanting vista of future possibilities. With some thirty different organic preparations to choose from, the possible combinations and permutations are practically limitless, and I note with interest that a recent panglandine preparation is said to contain parts of no less than 11 different organs of the body—assuredly a wide and practical recognition of the fact that when one endocrinous gland is damaged the whole glandular system is affected. Truly the elaborate mixtures which our medical forefathers were accustomed to prescribe become simplicity itself when compared with a tablet containing so remarkable a combination of substances; and we realise, too, how nearly they anticipated our modern therapeutic triumphs when they administered to their patients parts of various animals and insects, cockroaches, and the like. Incidentally one great advantage of polyglandular therapy is that should some of the ingredients fail to survive the destructive action of the digestive juices, a possibility which ought not perhaps to be absolutely ignored, there is at least the chance that others may be absorbed into the circulation, and so have an opportunity of giving rise to some of the potent effects with which they are credited; faith may be trusted to do the rest and complete the cure.

LETHAL CHAMBERS.

Finally, when the working years of life are past, men and women will be transferred to the care of a special medical department of the State dealing with old people, and with adequate pensions and amid comfortable and tranquil surroundings will await a peaceful ending to life, from painless senile decay. It is hardly to be expected, however, that the increasing infirmities of advancing years can be entirely avoided in all cases; it must still be true that "if youth is an intoxication, old age is the day after." Probably, if these infirmities became increasingly onerous, the question of lethal chambers, subject, of course, to strict medical control and adequate safeguards, would be considered.

DESPOTISM AND LAW.

Probably the greatest danger under a medical autocracy would be that of loss of freedom. A distinguished ecclesiastic once caused quite a grave

⁷ THE LANCET, 1922, ii., 319.

scandal by saying he would rather see England free than England sober. I think he was right, and I believe it would be equally correct to say we would rather see England free than England perfectly healthy. A despotism may be theoretically the best form of government if the ideal despot can be found, but he never can be, for human nature is so constituted that the mere fact of entrusting absolute power to an individual or a group of individuals soon renders them unfit to exercise that power over their fellow creatures. A medical despotism would be no exception to the rule. It is no sufficient answer to say that medical government would be necessarily in the best interests of the governed. A man's conception of what is best for his fellows may be absolutely disinterested and honest, his intentions may be wise and unselfish, but his conclusions and decisions may be erroneous, although the more convinced he is that he is doing right and that he is actuated by the highest and noblest principles, the more likely is he to become a tyrant. The exercise of uncontrolled power is almost always a cause of demoralisation, and "conscientiousness has to account for some of the darkest chapters of human history."

A second point we need to bear in mind is that health depends first and foremost on obedience to law—moral law and physical law, for they are of equal importance—and in the long run nothing which is morally wrong can be physically right. We speak of the laws of health, of the need for sufficient and suitable food, for pure drinking water, fresh air, adequate sleep, enough exercise, and so on; truly they all are essential; but there are moral laws, disobedience to which is eventually as disastrous to health and life, as is violation of the so-called physical laws. How many are the victims of lust, drunkenness, covetousness, making haste to be rich, and so on? We need to recognise that we live in a world which is under inexorable laws—moral and physical—from which there is no escape, try how we may, and that we can only be healthy and only be happy by learning what these laws are and setting ourselves steadily to obey them.

Lastly, there is a danger perhaps of dealing too much with secondary consequences rather than with primary causes. To attain as a community the highest possible standard of health we must have an intimate combination of socialism and individualism. We must strive for that fine civic ideal pictured in the stirring lines of Macaulay as applicable to ancient Rome—

Then none was for a party;
Then all were for the State;
Then the great man helped the poor,
And the poor man loved the great;
Then lands were fairly portioned;
Then spoils were fairly sold;
The Romans were like brothers
In the brave days of old.

—an ideal which doubtless existed only in the imagination of the poet, but which will have to be reached if ever we are to attain to the highest possible standard of national health. We need the harmonious coöperation of the whole community to provide those things which, under modern conditions of civilisation and especially of town life, the individual cannot provide for himself—adequate housing accommodation, good sanitation, pure drinking water, a sufficiency of fresh air, as good as environment as possible in shop, factory, and workshop, no excessive hours of work, efficient hospitals for cases of accident and serious or obscure illness—and a wage sufficient to enable a man to provide himself, his wife and a reasonable number of children with proper food, warmth, clothing, and recreation. Are we not, however, too apt to forget that all these things, however essential, are entirely insufficient without true individualism, without the determination of each man and woman in the community to obey the great moral and physical laws? A man may be placed in ideal surroundings and live under the best possible conditions, but he need not expect to enjoy good health if he does

not constantly strive to make the utmost use of his privileges, if he does not properly employ his money, his spare time, his opportunities; if he is immoral, if he drinks to excess, if he overeats, if he sacrifices physical exercise to ambition or to mere material prosperity. The old question ever arises, "Does the pig make the sty or the sty make the pig?"—in other words, is man the creator or the product of his environment? We have to recognise that for the attainment of ideal health and length of days both the man and his environment must be purified, uplifted, and ennobled. Just as in the political world it is useless, and worse than useless, to give democratic institutions to a people which has never been educated to use them aright, so in the world of health and hygiene it is equally useless to provide the most perfect surroundings and the most healthy external conditions of life for those who are too ignorant, too immoral, too careless, or too selfish to use them properly.

So we come back to the words of the wise man: "Let us hear the conclusion of the whole matter; fear God, and keep his commandments," that is, obey law, moral laws and physical laws equally. "for this is the whole duty of man." Thus, and thus only, not by constantly seeking short cuts to health, not by ingenious attempts to evade the results of law-breaking, not by merely tinkering with consequences rather than causes, can we ever hope to reach the ultimate goal of our ambitions and the final reward of our efforts—a genuine medical Utopia.

A CASE OF PERIARTERITIS NODOSA,

ACCIDENTALLY RECOGNISED DURING LIFE.

By E. ROCK CARLING, F.R.C.S. ENG.,

AND

J. A. BRAXTON HICKS, M.D., M.R.C.P. LOND.

THE earliest record of this condition was published by Kussmaul and Maier in 1886. Since that time about fifty cases have been described, the subject of this present paper being apparently only the fifth case to be recognised during life, and, we believe, the only patient who has so far recovered as to be able to return to work.

Clinical History.

The patient, a male, aged 30, an engineer, was sent to one of us (E. R. C.) by Dr. G. V. H. Fairhall, of Ladywell, in July, 1921. He stated that for a month he had had severe pain in the right calf, which eased off if rested, but by night, if he had been about on it, the leg "felt as if ready to burst." He had got very much thinner, and now felt "very weak." Upon further inquiry he added that at first he had pain also in the right wrist, and had for a time "lost the use of his hand." His personal history revealed nothing more than "rheumatic fever" at 7 years, and a mild attack of influenza in 1919. He had not served in the army, and venereal disease was denied.

Condition on Examination.—He walked with a pronounced limp, due to restricted dorsi-flexion of the right foot. The right calf, which measured half an inch more than the left in circumference, was tense and tender. In the substance of the sural muscles was a "lumpiness," which sometimes felt like one mass and sometimes like several adjacent nodules without discrete edges. There was slight oedema of the ankle and swelling along the tendo Achillis. Nothing else abnormal was found. Urine normal. Weight, 11 st. 5 lb. (last known weight was 12 st. 5 lb., three months previously).

A provisional diagnosis of gummatous infiltration, or just possibly a sarcoma, in the sural muscles was hazarded. The patient was admitted to hospital on July 13th, for observation. He was found to have an irregular fever of from 99° to 101° F. On the 14th the Wassermann reaction was negative and it was decided to explore the calf and submit a portion of the swelling for histological diagnosis.

Operation.—On the 15th the calf was explored, and the "lumpiness" proved to be not a "tumour," but small scattered nodules of a fibrous nature about the smaller arteries, around which the muscle fibres contracted spas-

modically, increasing their apparent size ten-fold, and then presently relaxed. Two or three of these nodules were excised for histological examination. A good deal of oedema was found under the deep fascia, in and between the muscles and in the connective tissue around the tendo Achillis.

As a result of the operation the patient lost the pain in the leg, but the fever continued for a week or two and very severe pains set in in both arms, which for a time were exquisitely tender. A few subcutaneous nodules appeared on the forearm and about the elbow, but at no time were any detected in the painful muscles. The further course of the case was uneventful, the pains were gradually ameliorated and the fever subsided, and "health" was gradually restored. The patient left the hospital and returned to work, declaring himself "quite well." His weight was then 9 st. 1 lb. He reported for observation in September and October, 1921, and again in March, 1922. He was still "quite well," and had had no return of pains; his weight was 10 st. 2 lb., and although there was general muscular wasting, especially of the arms and shoulder-girdle, he seemed quite comfortable and was at work.

Pathological Features.

The "nodules" were subsequently examined by one of us (J. A. B. H.) and it was at once recognised that the case presented unusual features.

A paraffin section showed the whole of the adventitia of an artery of medium size to be intensely infiltrated with small round cells. This infiltration was not only referable to the actual adventitia but to the fat and muscular tissue in the immediate vicinity. Even fairly remote tissue showed infiltration, which shaded off the further one got from the artery in question. Not only was the adventitia infiltrated but the media and intima as well. The intima and sub-intimal tissues were thickened by this infiltration, or, perchance, by an actual hyperplasia of these tissues. Thus the lumen of the vessel was narrowed, and it is to this that one can assume the cramps and pain were due. At first I could not assign a definite name to the condition, for it did not resemble any of the types of "arteritis" with which I was acquainted. Prof. S. G. Shattock very kindly identified the condition as "periarteritis nodosa," saying that the condition was rare and that he did not think that he had seen a similar section before. In the section the infiltrating cells appear to be all of the small round cell and elongated fibroblast types, and polymorphonuclear cells were not observed. It seemed that they must have arisen from the adventitia and had spread inwards, and not vice versa.

Other investigations on the pathology of the condition were carried out and a brief record is made below of what was found.

The Wassermann reaction was negative, both before and after a "provocative dose" of salvarsan substitute. The red blood cells and the hæmoglobin showed nothing of particular interest, save a slight diminution in their respective values. The leucocytes, however, throughout our observations have shown an increase. Thus:—

—	Total leucocytes.	Polymorphs.		Monomorphs.	
		Neutrophil.	Eosinophil.	Large.	Small.
	per c.mm.	%	%	%	%
July 26, '21	18,000	71	1	4	24
Aug. 9 "	30,000	86	—	8	6
Sept. 23 "	18,000	68	2	3	27
Oct. 28 "	15,800	74	2	2	22
Mar. 18, '22	14,000	67	3	9	21

It is of interest to note that the highest count is that of August 9th, 1921, and that during this time the patient was having the very severe attack of pain in the arms alluded to in the clinical account of the case. A bacteriological examination (aerobic) of the blood made during this attack remained quite sterile. On one occasion, as a matter of interest, I made an Arnetz count of the lobes of the polymorphonuclear nuclei, and the result was as follows: 1 lobe, 38 per cent.; 2 lobes, 44 per cent.; 3 lobes, 18 per cent.; 4 lobes, nil; so that the count is "moved towards the left," and this, according to Arnetz, is indicative of some form of chronic toxæmia. As infection by worms (*Strongylus armatus*, &c.) is known in animals to be associated with periarterial and endarterial changes, leading in some cases (horses) to fatal multiple aneurysms, the feces of this case were very thoroughly examined on two occasions, both before and after santonin followed by a saline purge. No evidence of any worm infection was found.

Animal Experiment.—An experiment was made in order to confirm (or otherwise) the observations of v. Haun. For this purpose 2 c.cm. of whole blood of the patient (which had been prevented from coagulating by the addition

of a drop of sterile 10 per cent. citrate) was injected into the peritoneal cavity of a guinea-pig weighing 270 g. (Pig A). The injection did not have any immediate ill-effects, and the animal remained in perfect health till it was killed four months and two weeks after. Two c.cm. of citrated heart's blood from Pig A was injected into the peritoneal cavity of a second pig (Pig B), 2 g. of limb muscle of Pig A were taken under sterile conditions, and minced up with sterile sand and saline (5 c.cm.) and the final "mince" incubated for 24 hours. The supernatant fluid (about 3 c.cm. by this time) was injected into the peritoneal cavity of a third pig (Pig C). Pig B was killed three months later, but Pig C died from acute pulmonary congestion seven weeks later. In none of the pigs A, B, and C were there any lesions of the peritoneum, nor obvious lesions of muscles or blood-vessels. Pig C had only the pulmonary changes seen in this not infrequent incidental trouble of the animal room. The muscles and aortæ of these three pigs were carefully microscoped, and nothing abnormal was noted in

Endarteritis and periarteritis nodosa: from a drawing showing a typical cross-section.

the sections. We cannot confirm, therefore, the observations of v. Haun, who claimed that he had been able to reproduce the human lesions by injecting the patient's blood into guinea-pigs, and carrying on from the original series into a second series of pigs. We purposely allowed our pigs to live a long while after the experiment had been started, to enable such lesions as aneurysmal swellings, &c., to develop if there was the slightest chance of this occurring.

Literature of the Subject.

The literature is already extensive. Perusal of the most recent papers, which contain digests of the earlier ones, and to which references are given below, show that the cases resemble one another closely.

Age and Sex.—Most cases are in young men, from 22–42, but women are not exempt, and a case is noted in a man of 62.

Nationality.—German, Russian, French, Italian, and British names appear in the list.

Previous Illnesses.—Many patients had a clean bill of health; syphilis was frequently absent; for the most part such exanthematous or infective disorders as were recorded were long antecedent; no causal connexion was traceable.

Initial Symptoms.—The common initial symptoms are great weakness and pains in the limbs; loss of flesh going on to emaciation; colic and diarrhoea which may be bloody; painful nodules, intramuscular or subcutaneous, which, as with the symptoms, may be transient and recurrent. Oedema of the feet.

Diagnosis.—Hitherto recognition of the condition in life has only been made after a biopsy. The diagnoses offered before necropsy have been trichinosis, miliary tuberculosis, polymyositis, arteriosclerosis, neuritis, purpura, typhoid, myasthenia, acute pancreatitis.

Death.—Has usually resulted from uræmia or from asthenia following progressive emaciation, but also from other causes.

Blood Examinations.—These show a leucocytosis, sometimes with excess of polymorphs, sometimes transitional cells, sometimes monomorphs, and often a slight excess of eosinophils. Blood cultures, both aerobic and anaerobic,

which have been recorded, have generally been sterile. A staphylococcus and a streptococcus have been recovered, but both observations are admittedly open to doubt.

Urine.—Whilst sometimes normal, in many of the fatal cases nephritis has been the cause of death. A marked polyuria has been recorded.

Experimental Production.—Whilst Klotz and Lamb's results were negative, those of v. Haun, who injected blood from his patient into guinea-pigs, and inoculated emulsions of the organs of these into a second series, were lesions analogous in their gross appearances, in their situation, and in histology, to those characteristic in man.

Nature of the Disorder.

The disorder, seemingly a specific infection, is characterised in its early stages by an inflammatory infiltration of the adventitia of the smaller arteries and arterioles, which spreads to the media; this it breaks up by fibrinous exudate; then disintegrates the elastic lamina and invades the intima. The infiltration, though polymorphic in its initial stages, shows the succession of cell changes which are witnessed in those early reparative processes which lead to the formation of granulation tissue and eventual cicatrization. The intima, which is much thickened, shows sometimes a hyperplasia with stratification of its proper cells, such as is seen in endarteritis, but the thickening is to a large extent by granulation tissue which has appeared to many observers—and to us—to be an irruption from without, but it is right to say that the opposite direction—from intima outwards—is held by others to be the true course of the process. The results of the process, however initiated, are the formation of multiple aneurysms which either rupture with the formation of arterial hæmatomata; or thrombose and lead to infarcts or local necrosis, or degeneration in parenchymal tissues supplied; or cicatrize and recanalise and permit local recovery. The results to the organs are ulcers and hæmorrhages in the wall of the stomach and intestines, degeneration with or without infarction of the kidneys, liver, spleen, testicles, adrenals, pancreas, and heart muscle.

The characteristic picture at necropsy is of multiple aneurysms, some healed or healing, on the renal, hepatic, gastric, mesenteric, splenic, testicular arterioles, and those of the heart; occasionally those of the limbs, and rarely others. The viscera show the associated lesions that might be anticipated. Many of these aneurysms are as small as a grain of rice; the largest not bigger perhaps than a pigeon's egg. Attention has been drawn by several observers to the very similar disorder found in the horse, stag, calf, pig, and dog. In the horse the aneurysms, which are due to the larvæ of an intestinal worm, *Strongylus armatus*, variety *Sclerosomum bidentatum*, are found chiefly in the course of the anterior mesenteric artery, but occasionally in the visceral arteries, though apparently not in those of the limbs. The symptoms in the horse are very similar to those in some human cases—with severe colic, great muscular weakness, distress, and emaciation. It is a fatal disorder. The path by which the larvæ reach the walls of the arteries is not certainly known, but is probably via the adventitia and vasa vasorum. It is noteworthy that our patient's recovery followed upon intravenous injection of salvarsan substitute.

Note.—Since this paper was written Harris and Friedrichs (*Journal of Experimental Medicine*, 1922, xxxvi., 219) have transmitted the disease to rabbits, and shown that the virus is a filter-passer.

THREE CASES OF PARAPLEGIA FOLLOWING INFLUENZA.

BY H. WILLOUGHBY GARDNER, M.D.,
F.R.C.P. LOND.

THREE cases of paraplegia following influenza have recently come under my care. Two were of recent occurrence, the third dates from the autumn epidemic of 1918.

CASE 1.—The patient was a motor mechanic, aged 35, whom I saw in consultation with Dr. W. A. Lewis, of Oswestry, on Feb. 21st, 1923. He had then complete flaccid motor paralysis below the ninth dorsal level, with loss of all deep reflexes, and loss of sensation to touch, pain, and heat and cold over the corresponding area. The bladder and rectum were also completely paralysed. The history given was that he had fallen ill a month previously with what was thought to be influenza and that his wife and children and other members of the household had also suffered from it. He complained of dimness of vision and was noticed to have some retraction of eyelids with some slight protrusion of eyeballs. He was only ill for about a week, saw no doctor, and was only away from work for three days. About two weeks later he was down with a second influenza-like attack, again associated with dimness of vision, and this time with severe headache. The next day, Feb. 15th, he complained of stiffness and weakness of the legs, but walked round the room with his wife's help. On the 16th Dr. Lewis found him completely paraplegic, with a distended bladder, of which he was quite unconscious. There was at first but little loss of sensation, but all deep reflexes were absent. Trying to get out of bed he had fallen and bruised his sacrum; this bruise rapidly developed into an extensive bed sore.

When seen on Feb. 21st he complained of a curious defect of vision, and was found to have double optic neuritis and altitudinal hemiopia, especially of the right eye, the lower half of the fields of vision being deficient. He had been delirious the last few nights, though his mind was perfectly clear by day. He was moved next morning into the Royal Salop Infirmary, but by the time he arrived there he had developed acute hæmorrhagic cystitis and a large sloughing bed sore. He lived for about ten days, during the greater part of which time his mind was clear during the day, but he was wildly delirious at night. His death seemed chiefly due to the huge sloughing bed sore. The cystitis was rapidly clearing up under treatment, but the paralysis remained unchanged.

The initial "influenza," the early eye symptoms, the relapse, the headache, the double optic neuritis, the intensely hæmorrhagic nature of the cystitis and the wild nocturnal delirium and sleeplessness with mental clearness during the day seemed to point to an encephalitis accompanying the myelitis and to render it probable that the disease was essentially the same as encephalitis lethargica, but that its stress had fallen upon the spinal cord instead of the brain.

CASE 2.—A student, aged 21, was sent to me from Corris, Merionethshire, by Dr. E. C. B. Ibotson. His illness began on Jan. 4th, 1923, as an attack of influenza, from which other members of his family were suffering at the same time. It commenced with a rigor and he had severe pain in back and hips; his legs were weak and he was unable to sit up. He rapidly improved, and on the 11th he went for a 12-mile walk. This proved too much for him; he returned with difficulty, somewhat collapsed, and had to be put to bed at once. Motor paralysis from the waist downwards rapidly supervened. For the first three days there was loss of control of the bladder, but there have been no micturition troubles since.

He came into the Royal Salop Infirmary on March 10th. He was then found to have complete flaccid motor paralysis of both legs from the hips downward, with the exception of the toes of the left foot, which he could move fairly well. There was no loss of sensation, and there was slight flexor response in both feet, but the deep reflexes were absent and there was marked wasting. No contraction was obtained with the faradic current in the affected muscles. There seemed, however, to be no tendency to bedsores. Since admission there has been no definite improvement of the paralysis, though the patient's general condition, which was very poor, is better.

The points of resemblance between this case and the first are obvious—viz., the initial "influenza" affecting other members of the household, the early improvement and relapse following upon over-exertion, the complete flaccid paraplegia, showing no tendency

to get better, and the involvement of the bladder. In the second case the illness has been far less severe, and its stress seems to have fallen entirely upon the spinal cord, no cerebral symptoms having been noted.

CASE 3.—The patient is a woman, aged 21, in whom weakness of the legs followed a severe attack of influenza in November, 1918, with little change since. She is able to walk, but soon tires, and the left foot especially droops owing to weakness of the peronei. The knee-jerks are very slight and the ankle-jerks absent, but she has a well-marked extensor response in either foot. The unchangeable nature of the symptoms and the complete absence of any of the psychical or other symptoms characteristic of disseminated sclerosis differentiate the case from that disease; the presence of extensor response and the symmetrical distribution of the paralysis render it unlike anterior poliomyelitis. I think there can be little doubt that it has been a case of myelitis similar in its nature to the other two cases.

Remarks.

The occurrence of three such cases, two of them dating from the beginning of this year, makes one wonder if other cases are occurring in sporadic form throughout the country, possibly in sufficient numbers

to constitute a mild epidemic. As the three cases seem to be of the same nature, and the first case in many respects resembles encephalitis lethargica, I am inclined to think that all three have been really cases of that disease and ought to be notified as such, and that there are probably many others like them.

Dr. F. G. Crookshank tells me that many such cases have been described by American, German, and Italian writers as spinal types of encephalitis lethargica; he quotes Hippocrates as describing an epidemic of paraplegia occurring in the winter months followed by epidemics of "burning fevers" in spring, summer, and autumn—such burning fevers having been in all probability influenza. One practical point emerges from these histories. In the first two cases the paralysis definitely supervened upon over-exertion too soon after the initial attack of influenza; it is evident that we cannot be too careful to prevent over-exertion whenever there are early symptoms of weakness in the legs or symptoms pointing to a possible encephalitis.

Shrewsbury.

Clinical and Laboratory Notes.

A CASE OF INTUSSUSCEPTION STARTING IN A LARGE MECKEL'S DIVERTICULUM.

BY NOEL L. HOOD, M.D., B.C. CAMB.,
HON. SURGEON, YORK COUNTY HOSPITAL.

IN the case about to be described the patient was a boy, aged 8 years, apparently healthy, with no history of illness except a recently fractured elbow.

Present Illness.—For several years he had had occasional attacks of pain in the abdomen, almost always about bed-

and the minimum exposure of abdominal contents were main objects, and the lump was rapidly withdrawn from the abdomen and packed round. A very brief attempt to reduce the intussusception showed that this was unlikely to succeed, and that the condition of the gut was beyond reasonable hope if it did. The whole mass was therefore resected with a margin of healthy gut beyond at each end and an end-to-end anastomosis done. About 13 inches in all (after reduction) were removed, and the abdomen was filled up with hot saline and closed as quickly as possible. Recovery was uninterrupted and uneventful.

Specimen.—The intussusception was reduced after the operation with considerable difficulty and was in part definitely gangrenous. The involution began at the tip of a Meckel's diverticulum, where there was a dimple which persisted. It is an exceedingly pretty specimen (see illustration) and the complete intussusception could, with the aid

Portion of gut removed at operation, showing the intussusception: (1) removed, (2) partly reduced, and (3) wholly reduced, with the starting place shown by the dimple at the tip of the diverticulum.

time, which were relieved by a hot-water bottle. On Sept. 2nd, 1922, he walked round an 18-hole golf links with his father, had a hearty dinner on returning home, played ball in the garden, had a few ripe plums, and went to bed apparently perfectly well and in excellent spirits at about 8 P.M. Two hours later he woke with pain in the body and vomited. He was given some hot water, which he vomited, and then half an aspirin tablet and a teaspoonful of brandy. He seemed easier for a time, but had a bad night; on the morning of the 3rd he looked drowsy and ill and had severe pain in the right side, with a temperature of 99° F. Dr. E. O. Libbey, of Scarborough, was sent for, and saw the patient about 11 A.M. An enema was administered almost at once with a slight result, and about three-quarters of an hour later the patient passed a large, very offensive, motion with a considerable quantity of blood. Dr. Libbey saw him again about midday, found that a lump felt on his previous visit had not disappeared, and ordered immediate operation. I was sent for from York; pending my arrival the child was seen by Dr. J. Reid Dick, of Scarborough, and removed to a nursing home.

Operation.—I saw him about 4 P.M., and as the condition was obviously one of "acute abdomen" with an egg-shaped lump a little internal to the usual position of the appendix, and he was passing blood and slime at intervals, I spent very little time over any examination and operated at once. Seeing the child was not in a state to stand much, rapidity

of a long pencil, be reproduced, and reduced again by "milking" it back at will.

I have to thank Dr. Libbey for his prompt action and for an excellent anaesthesia, and Dr. Dick for very valuable and skilful assistance at the operation.

A CASE OF INTESTINAL OBSTRUCTION.

BY S. SUBBA RAO, M.B. MADRAS, M.R.C.S. ENG.,
MEDICAL OFFICER IN CHARGE, VICTORIA HOSPITAL,
BANGALORE, S. INDIA.

ALTHOUGH intestinal obstruction is fairly common, yet obstruction due to the formation of a complete adventitious sac by a process of chronic adhesive peritonitis is a rare condition. I have not found a case similar to the one here described in the surgical literature immediately available.

The patient was a woman aged 20 years, short, sparely built, and greatly emaciated. She had a history of frequent attacks of intestinal colic for over a year, and complained

that a few hours after taking food a round lump appeared in the right side of her abdomen, and moved all over the abdomen with a gurgling noise, causing excruciating pain. The attack generally lasted for an hour or two, and ended with vomiting. At first these attacks were few and far between, and the lump was small; but for the past six months they had occurred almost every evening, and lasted for longer periods. The lump grew steadily larger, and she had recently been unable to take any solid food for fear that the pain would increase. There was also a history of obstinate constipation.

Condition on Examination.—The patient was ill-nourished and anæmic. The only physical sign present was an ill-defined lump in the right iliac fossa, which felt much like a thickened coil of intestine; pressure over this produced a gurgling sound. Her troubles were at first attributed to hysteria, but a few days after admission I saw the patient in one of her periodical attacks of colic. It was a remarkable sight: a great coil of distended gut, almost as large as the tyre of a motor bicycle, was seen running obliquely across the abdomen from the right iliac fossa to the left lumbar region. There was marked visible peristalsis, accompanied by occasional gurgling. The abdomen was greatly distended and tympanitic to percussion, and the patient suffered agonising pain. A diagnosis of chronic obstruction was made, and exploratory laparotomy was decided upon.

Operation.—A median incision was made below the umbilicus and a small amount of clear serous fluid was found in the peritoneal cavity. A white glistening mass about the size of a large orange was brought out of the incision. It had a peculiar wormy feel, not unlike an intussusception. On tracing it, the lower end was found to be continuous with the last inch or two of the ileum, near its junction with the large intestine; and the upper end of this mass was found to be continuous with a loop of ileum, which was enormously distended and covered here and there with flakes of coagulated lymph. The mass, together with the dilated loop of gut, was clamped and removed, a triangular piece of mesentery being also excised. The remaining ends of the intestine were closed by the usual Czerny-Lembert sutures, and a lateral anastomosis was performed between the ileum and the ascending colon.

Recovery.—On the ninth day after operation sutures were removed. The patient made an uneventful recovery, and was discharged cured about a month after the operation; her general condition had greatly improved.

Specimen.—The mass removed was ovoid in shape, measuring 6 in. in its long diameter and 3½ in. in its short diameter, and was found to consist of a complete adventitious fibrous sac probably formed by the organisation of sero-fibrinous exudation. On carefully dissecting into the sac, it was found to contain five loops of small intestine closely compressed and adherent to each other, and measuring 4 ft. 2½ in. in length. The dilated and hypertrophied portion of gut above the adventitious sac was 3½ in. in width and 1 ft. 1½ in. in length. Thus a total length of 5 ft. 4 in. of ileum was successfully removed.

I am indebted to Dr. J. Jhirad for able assistance at the operation.

A NOTE ON THE TREATMENT OF CHRONIC ULCERATION OF THE LOWER EXTREMITIES.

By R. KELSON FORD, M.R.C.S. ENG.,

LATE OF THE BAPTIST MISSIONARY SOCIETY, TAI YUAN FU,
SHANSI, NORTH CHINA.

FEELING, as I do, that the line of thought followed below deserves considerable attention, I venture to quote a single case in its support. Chronic non-specific ulceration of the legs and feet is a condition too well-known to need description here. Treatment is usually very tedious, and the complaint is often a cause of despair to the sufferer, and of exasperation—or apathy—to his attendant, especially in the case of those patients who, finding it difficult to lie up for a long period, are the chief sufferers.

The bluish discoloration of the skin seen in the more stubborn of these cases is a sign of deficient blood-supply. It is in some instances a precursor of ulceration, and always a most potent factor in the delay of cure. Hence, any measures which tend to increase the circulation of the part may be expected to hasten cure very markedly. Acting on the theory that the arterial supply to the extremity is increased by dilatation of the artery consequent on paralysis

of the nerve plexuses in its walls, Leriche¹ practised the operation of sympathectomy. Removing a portion of the wall of the femoral artery to interrupt the vaso-constrictor fibres, he obtained peripheral dilatation in the leg. This effect started to pass off before the end of a week, and had ceased to be evident after a month. This method he used for such conditions as Raynaud's disease, trophic ulceration, prevention of gangrene, &c. Following on this, but desiring to produce a more prolonged effect, Mr. Sampson Handley² employed alcohol by injection into the walls of the femoral artery, and successfully treated cases of already established gangrene by this means. Few would deny that injection is simpler and safer than sympathectomy, and the results so far do not seem to show any advantage in favour of the latter. Further, sympathectomy was done for simple conditions, such as trophic ulceration; I would therefore ask—could not the method of vaso-constrictor blockage be applied to all forms of ulceration of the extremities? Alcohol, however, presumably paralyses these plexuses for at least a year (arguing from analogy—e.g., in the case of its employment for the treatment of trigeminal neuralgia), which is considerably longer than may be supposed necessary in the case of ordinary ulcerations.

In the following case, therefore, a local anæsthetic was employed instead:—

A Chinese male, aged 52, who had come two days' journey by cart for treatment, was admitted to the Mission Hospital, Tai Yuan Fu, early in September, 1922, suffering from chronic ulceration of the right ankle and dorsum of the right foot of several months' duration. The skin surrounding the affected area was bluish. The ulceration was superficial, though there was one area of about the size of a florin on each side of the ankle which was deeper. No history suggestive of syphilis was obtained.

The region was first cleansed by soaking daily in warm hypertonic saline solution for ten days, dry dressings being applied at night. During this period no improvement was noted apart from removal of crusts, discharge, &c. The common femoral artery was then exposed under chloroform anæsthesia, its sheath opened and its walls injected with 5 per cent eucaine solution at one point in each quadrant of its circumference. Less than 0.5 c.cm. of solution was used altogether.

The dressings applied before operation were left undisturbed until the fourth day after, when all superficial ulceration was found well healed; the skin was of normal healthy colour and the two deeper ulcers had markedly improved. They healed rapidly afterwards. The only complaint by the patient was of some tingling in the left thigh and leg on the day after operation. He was only under observation for a further fortnight, during which nothing untoward was noted, and was discharged as cured.

Remarks.

It might be suggested that the simple rest and cleansing fully account for this result, but I am strongly of opinion that it was much too striking to be disposed of in that fashion and did not occur in other cases treated only by these means. The ulcers were not merely dried, but were firmly healed, and the surrounding skin was uniformly of a healthy appearance. Never before have I seen such a rapid and satisfactory result as this, though it is regretted that the patient could not be followed up.

Circumstances unfortunately prevented repetition of this experiment. This case is reported, however, as it appears probable that such a procedure may prove of benefit in other cases of this description, and possibly also in those of varicose ulceration of the lower extremity. Should it appear desirable to aim at prolonging vaso-dilatation somewhat, the use of quinine urea hydrochloride (½–1 per cent.) in conjunction with eucaine or novocaine might prove effective, though some hold that it only acts on nerve terminals. In cases where there is no fear of gangrene, this method might prove of equal service in cases of bilateral affection, and even in cases of early gangrene it appears to me to offer chances, by reason of its transient effect, not available by any other means.

Portsmouth.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF SURGERY; SUB-SECTION OF PROCTOLOGY.

ULCERATIVE COLITIS.

A MEETING of this sub-section was held on May 9th, with Sir CHARTERS SYMONDS, the President, in the chair. Sir HUMPHRY ROLLESTON introduced a discussion on Ulcerative Colitis. His remarks appeared in full in THE LANCET of last week.

A Disease of Low Resistance.

Sir THOMAS HORDER said that one of the most striking features of the disease was its chronicity; by the use of the sigmoidoscope ulcers were still visible when all symptoms had disappeared and the disease was apparently cured. He therefore regarded the disease as a general one of low resistance to a certain infection, resembling in this respect pulmonary tuberculosis. As regards treatment, appendicostomy was required only if the patient were in a low state; if the disease was less severe much could be done by simple rest in bed in the open air. The Trendelenburg position should be adopted for a few hours every day in order to relieve the congestion of the colon which was one of the features of the disease. The diet should be as full as the patient could tolerate without causing diarrhoea. He found tonic intramuscular injections useful and employed vaccines as supplemental to this treatment, but without placing much reliance on the latter. Normal horse serum was also of use. There was a danger from over-energetic measures; in one case marked improvement followed the cessation of all treatment other than rest and dieting, where the patient had been going rapidly downhill under more vigorous measures. In all cases patients should be warned that a long convalescence was inevitable; three months should be allowed to elapse after the cessation of active symptoms before the patient was allowed to return to his ordinary activities.

Improved Results from Appendicostomy.

Mr. J. P. LOCKHART-MUMMERY pointed out that since the last discussion upon this subject, when the mortality of the disease was about 50 per cent., there had been a notable improvement in the results of treatment of the disease. Thus amongst 70 cases, which included all those at St. Mark's Hospital and in his private practice during the last nine years, the mortality was 15 per cent. The disease, which started in the solitary follicles from which ulceration spread to the surrounding mucosa, showed striking variations in severity; there might be a solitary ulcer or almost the whole surface of the colon, an area about half that of the body surface, might be involved. In many cases the disease arose from secondary infection with other organisms of a colon previously damaged by bacillary, amœbic, or sand dysentery. In one case a man who had previously suffered from several mild attacks of dysentery had, after drinking milk infected with streptococci, developed a severe ulcerative colitis from which he almost died. It was the variation in the organisms of secondary infection which was responsible for the differences in severity of the disease; the commonest were a paratyphoid bacillus and streptococci and staphylococci. The best results in treatment were obtained by appendicostomy, combined with the replacement of the organism of secondary infection by the Bulgarian bacillus, when the latter was possible; the method by which streptococci and staphylococci could be replaced had yet to be learned. A specially interesting type of ulcerative colitis was due to pneumococcal infection; two cases of this kind had occurred in his practice, both characterised by excessive hæmorrhage and a high temperature; neither case had pneumonia. Diagnosis could only be made by means

of the sigmoidoscope, and by means of this instrument it was possible to observe the natural healing of the ulcers. It was remarkable that healing was often complete; only in exceptional cases was there any appreciable scarring after the most severe ulceration. Stricture of the colon was therefore very rare, except as a sequel to the operation of cæcostomy. For this reason he preferred appendicostomy to cæcostomy in the surgical treatment; the former had the added advantage of being a procedure possible under local anaesthesia when the patient was in extremis. A catheter should not be tied into the stoma but passed as required, and the stoma should not be allowed to close for at least 12 months. As regards the solutions used for irrigating the colon, these should be non-toxic and preferably hypotonic to avoid dehydrating the patient, and they should be used at blood heat. Some of the silver salts were excellent, but silver nitrate should not be employed, as Mr. Lockhart-Mummery had seen a case of severe argyria from its use. Of all solutions the speaker liked best a hypotonic solution of sea salt, while solutions containing the Bulgarian bacillus were also excellent. Finally, the patient should be warned of the probability of recurrence from trifling exciting causes, such as chill.

Bacteriology of Ulcerative Colitis.

Dr. W. E. CARNEGIE DICKSON said that while the primary organism responsible for ulcerative colitis might be one of very many, such as the *Entamoeba histolytica*, *B. dysenteriae*, *B. paratyphosus*, *B. pyocyaneus*, the pneumococcus, streptococcus, or enterococcus, &c., the infection speedily became a mixed one. This was an essential point to be remembered in treatment by vaccines and sera. Thus in some forms of bacillary dysentery in which a vaccine of the bacillus could not be used on account of its extreme toxicity, the specific serum might be used with a mixed vaccine from the organisms of secondary infection. When treating cases of ulcerative paratyphoid infection with vaccines he had greater success from such mixed vaccines (including the patient's own strain of *B. coli*, streptococci, &c.) than from a pure autogenous vaccine of the primary organism. Originally he had laboriously isolated the various organisms and prepared a vaccine from the one which appeared to be the causal one, but now, by using a variety of culture-media, he was able to obtain a mixed bacterial emulsion closely resembling the mixture of organisms seen in a direct film. From this emulsion he made the vaccine. By this method he was able to grow all the organisms concerned in a few days, an advantage when a report was required as to the nature of the organisms, since the full scientific investigation, by isolating each individual organism, might well occupy weeks or months. Further, during this period fresh organisms, originally kept in check by others, often appeared. Most of these slowly-growing organisms were fortunately unimportant, although one such, the *B. pyocyaneus*, was, he thought, of considerable importance in connexion with colitis. This organism he had found in a number of cases of colitis often associated with severe ulceration and hæmorrhage, and in some of these cases, which clinically resembled paratyphoid fever, he had been able to obtain the organism from the blood and urine. Dr. Dickson emphasised the importance of regarding mixed vaccines as only one item in the treatment, which should include the eradication of a focus of infection in the teeth, sinuses, or the appendix, if such a focus could be found. The last source, the appendix, he believed often acted as a reservoir for the organisms after they had been driven out of the colon; a member of his family who had suffered from intermittent attacks of colitis for nine years had been cured by appendicectomy at the age of 10. It was interesting that cases of colitis commonly exhibited a leucopenia chiefly affecting the polymorphs; he suggested that the beneficial action of normal horse serum was due to its action in raising the white-cell content of the blood. In conclusion, Dr. Dickson suggested that the disease might be in some way connected with vitamin deficiency.

Ulcerative Colitis and Bacillary Dysentery.

Prof. L. S. DUDGEON, whose communication was read by Dr. A. L. URQUHART, referred to the divergence of views as to the identity or otherwise of ulcerative colitis and amoebic or bacillary dysentery. While Sir W. Hale-White believed the diseases were distinct, such an authority on dysentery as the late Dr. F. M. Sandwith held that ulcerative colitis was dysentery occurring in a population where dysentery was not endemic. Dr. Sandwith supported this belief by referring to the identity of the symptoms during life, and of the lesions as seen in the post-mortem room. Dr. H. P. Hawkins, in 1908, concluded that better bacteriological methods would lead to a solution of the problem, and for this purpose obtained scrapings from ulcers visible through a rectal speculum. From this material Prof. Dudgeon was able to isolate a Flexner bacillus from a case of ulcerative colitis, although repeated examination of the stools had been negative. Bacteriologists with experience of bacillary dysentery knew how difficult it was to isolate the organism from faecal material, so that Dr. Hawkins's method was of special value and had been adopted by Manson-Bahr and Gregg. Since the war six cases of sporadic so-called "ulcerative colitis" had yielded in one case a Flexner bacillus, in four a hæmolytic colon bacillus in almost pure culture, and in one case hæmolytic streptococci and a *Staphylococcus aureus*. He had not met with a case of ulcerative colitis from which an amoeba had been isolated or which had had a liver abscess. The lesions of ulcerative colitis always resembled closely those of bacillary dysentery; in the East during the war he had, however, seen similar symptoms and similar lesions in cases yielding *B. paratyphosus* B or C. He was therefore opposed to the view that ulcerative colitis and true dysentery were of necessity caused by the same organisms. In every case the infective agent could be determined by an investigation on the following lines: (1) Examination of the bowel by means of the sigmoidoscope. (2) If ulceration were present, material from the floor of the ulcer should be submitted to detailed bacteriological and protozoological investigation. (3) Repeated examination of the faeces. (4) Examination of the blood, more especially in relation to the presence of immune substances in the serum.

Value of Antidysenteric Serum.

Dr. A. F. HURST said that the first description of the sporadic ulcerative colitis occurring in England was published in 1875 by Sir Samuel Wilks, who pointed out that it was anatomically indistinguishable from dysentery. Saundby in 1906 and Hawkins in 1909 came to the same conclusion as a result of clinical and pathological investigations but without using the sigmoidoscope. In a report on an epidemic of "idiopathic ulcerative colitis," which resulted in 118 deaths in the Lancaster County Asylum in 1898, Gemmell expressed his belief that this condition, which had always been well known in asylums, was really dysentery. Vedder and Duval, working under Flexner in 1902, proved that epidemics of "dysentery" occurring in institutions in America were caused by the *B. dysenteriae*, and two years later Eyre showed that asylum dysentery in England was also caused by this organism. All attempts, however, to isolate the bacillus from sporadic cases had failed, though in a small number the blood had strongly agglutinated Flexner's bacillus. A diagnosis of ulcerative colitis could only be made with the sigmoidoscope. It was first necessary to exclude a growth beyond the reach of the finger. It was then necessary to decide what form of colitis was present, to ascertain the severity of the condition, and to exclude the possibility of amoebic dysentery, even if the examination of the stools had proved negative, for Dr. Hurst had seen a few cases in which this infection developed in patients who had not been out of England. An anæsthetic was very rarely required, as the passage of the instrument did not cause pain unless the anal canal was inflamed; in such cases a cocaine semple should be introduced a quarter of an hour before. If the sigmoidoscope was

carefully introduced under visual guidance without inflation and only as far as it went without difficulty, there was no danger, the few cases in which perforation had occurred having all apparently been due to its blind passage. In ulcerative colitis the mucous membrane was bright red and thick, the swelling being particularly obvious in the normally thin Houston's folds. It bled very readily when touched, and its surface was covered with blood-stained, purulent mucus. Superficial ulcers were invariably present, but in early cases they might be so small that they were difficult to recognise. More frequently they were of larger size and were sometimes so extensive that only small islets of mucous membrane were left, which might feel like small, flat polypi on rectal examination, the floor of the ulcers being mistaken for the surface of the mucous membrane. The ulcers were always superficial with irregular edges, and the thick mucous membrane was not undermined. The floor of the ulcers appeared greyish-yellow when the blood and mucus were wiped from their surface. In some cases the sigmoidoscope showed that the rectum or the rectum and lower part of the pelvic colon were alone inflamed, as normal mucous membrane was found higher up, but it was doubtful whether the proximal part of the colon was ever involved without the pelvic colon and rectum. Dr. Hurst had often watched with the sigmoidoscope the process of healing. When healing occurred new mucous membrane formed; owing to the superficial nature of the ulcers very little scarring occurred and strictures never developed. When the sigmoidoscope was passed after complete recovery from ulcerative colitis or bacillary dysentery, nothing more was seen than some very slightly puckered areas in the mucous membrane, which might be a little paler and smoother than normal. During the war Dr. Hurst had several opportunities of examining the colon with the sigmoidoscope in cases of acute dysentery, and since then he had examined a considerable number of chronic cases in the same way. The differences between the appearance of the mucous membrane in amoebic and bacillary dysentery were so marked that a diagnosis could be made with the sigmoidoscope of one from the other with a considerable degree of certainty. He was much struck from the first, however, with the fact that the appearance of the mucous membrane in bacillary dysentery was indistinguishable in life, as Wilks had observed post mortem, from that of the sporadic ulcerative colitis which occurred in England. On the other hand, in amoebic dysentery small, round, red elevations were seen on the otherwise normal-looking mucous membrane, corresponding to the collection of broken-down material in the submucous tissue caused by the invasion of the *Entamoeba histolytica*. In the centre of each elevation was a depressed yellowish ulcer, caused by the rupture of the submucous abscess through the mucous membrane.

In view of the very favourable effects Dr. Hurst had obtained in chronic as well as acute bacillary dysentery by the intravenous injection of large doses of the polyvalent antidysenteric serum of the Lister Institute, he decided to try the effect of the same treatment in ordinary ulcerative colitis. The results had been remarkably favourable. They were not, he believed, due simply to the use of horse serum, but were definitely specific. In a severe case under his care he tried the effect of large doses of ordinary horse serum; no improvement resulted, but the administration of antidysenteric serum after a week's interval had the usual rapidly favourable result. He generally began with an injection of 40 c.cm. intravenously; this was followed on consecutive days by injections of 60, 80, and 100 c.cm. The four injections were often sufficient, but it might be necessary to repeat the maximum dose two or three times. A considerable reaction often occurred; the patient's temperature rises and a profuse erythematous rash appears. The joints might become swollen and painful. But these symptoms generally only lasted a few hours, and never longer than a few days. Dr. Hurst thought they were less likely to occur if 15 gr. of calcium lactate were given three times a

day, the day before and during the days of treatment. No anaphylactic symptoms had been observed, even in patients who had previously had serum, but care was always taken to desensitize the latter by very small preliminary injections, and the same precautions would be necessary in any patient who was subject to asthma. He had used this treatment in about ten cases. Very rapid improvement had always occurred, though in one case in which appendicostomy had been performed some months earlier it was incomplete. A secondary streptococcal infection had apparently become grafted upon the original dysenteric infection, as complete recovery only took place after the removal of the teeth, which was followed by a temporary severe local reaction. An attempt to treat this patient with a vaccine prepared from streptococci isolated from the stools had to be given up owing to the violent reaction which followed the injection of only a quarter of a million bacteria. His colleagues, Dr. John Fawcett and Dr. J. A. Ryle,¹ obtained an equally satisfactory result in one case under their care. The treatment failed in two others, but in both of these they recognised the ulcerative colitis as being of a hypertrophic character quite different from the ordinary type, so that in all probability it was caused by a different infection. One of these cases died shortly afterwards from perforation, which rarely, if ever, occurred in the usual form of ulcerative colitis, and in the other an appendicostomy, which was subsequently performed, led to no further improvement. Dr. B. E. Jerwood² had also reported a case in which the patient was "incontinent, very weak, wasted, and quite determined to die," and in which rapid recovery followed treatment with antidysenteric serum.

In most cases the improvement was as rapid as that of amoebic dysentery with emetine and epidemic bacillary dysentery with intravenous antidysenteric serum. In Dr. Hurst's first case the patient was so ill when first seen that he advised an immediate appendicostomy. In spite of this the patient went steadily down hill, and a fortnight later, when the first injection was given, his condition appeared to be almost hopeless. But in three days the blood had disappeared from the stools; in five the sigmoidoscope showed that the mucous membrane was entirely free from ulcers, though still a little red, and in ten days the stools were normal and the mucous membrane was perfectly healthy, though the ulceration before the first injection was most extensive.

Dr. Hurst had discussed the details of treatment by rest, diet, albargin injections, and charcoal in the Guy's Hospital Reports for January, 1921, when he first described the results obtained with antidysenteric serum. They were of great importance before the introduction of the serum treatment, but recovery rarely took place in less than six months, and a year was often required. Until three years ago he was, therefore, inclined to advise appendicostomy as an additional measure in all cases of any severity. But since he had used large intravenous doses of serum he had not found it necessary to advise appendicostomy in a single case, and had only occasionally had recourse to albargin injections. He realised, however, that there must be cases, such as the two under the care of Dr. Fawcett and Dr. Ryle mentioned, in which the pathology was different and in which serum would be useless. In these the other methods of medical treatment and appendicostomy would be required. No case could be regarded as cured until the sigmoidoscope showed that the mucous membrane was perfectly healthy. It was then necessary to keep the stools soft by the use of paraffin or saline aperients for several weeks until the newly-formed mucous membrane had overcome its original vulnerability to mechanical irritation. He concluded with a plea for the more extensive use of the sigmoidoscope. It should no longer be regarded as an instrument for the proctologist or surgeon alone; it should be used by every physician, and to treat a case as colitis without first visually examining the

rectum and pelvic colon should be regarded as equally as absurd as the treatment of a case of tonsillitis without first looking at the tonsils.

A Surgical View.

Sir CHARLES GORDON-WATSON was much impressed by the results obtained by Dr. Hurst with antidysenteric serum, and thought that this form of treatment deserved a further trial. He agreed as to the identity of the lesions in ulcerative colitis and bacillary dysentery, and added that many cases of bacillary dysentery died during the South African War which might have been saved by the surgical treatment now employed for ulcerative colitis—namely, appendicostomy. This operation, if it were to be successful, must be performed early; there was still a tendency to call in the surgeon only when the patient was in extremis. In a recent case, for instance, a patient died of a perforation which occurred on the morning fixed for operation. The stoma should not be allowed to close too soon. As regards a primary focus, he had on one occasion found a subacutely inflamed appendix which he removed, thereby curing the patient, and in another case drainage of an antrum had cured a patient who had had repeated attacks. He also had seen severe reactions follow the extraction of two septic teeth, but cure in this case was much delayed. After a trial of many fluids he had found flavine the best for irrigation of the colon. On one occasion only had he found a vaccine helpful; this patient had had several attacks since 1911, when an appendicostomy was performed, and was going downhill in spite of reopening of the appendicostomy, when a mixed vaccine cured him for a time.

Mr. DOUGLAS DREW had given up appendicostomy since he had had a fatal case, and now always performed cæcostomy. He gave details of one case where cæcostomy had produced temporary benefit; a severe relapse occurred and he was persuaded to operate again with a view to performing colectomy, which, however, proved impossible owing to the condition of the bowel. He therefore brought the cæcum out at the middle line as a permanent colostomy with a definite improvement for two years.

The PRESIDENT remarked on the fact that whereas some cases were reported as cured by a certain form of treatment, others appeared to be refractory and were in no way benefited by the same treatment. He also commented on the success which had attended appendicostomy and the valuable results obtained by some of the speakers with antidysenteric serum.

Reply.

Sir HUMPHRY ROLLESTON, in reply, said that it would appear that the majority of cases of chronic ulcerative colitis were, in fact, cases of bacillary dysentery from which the organism could not be recovered. The physician regarded the disease from the point of view of a general condition, whereas the surgeon devoted his attention to the local condition. Since stricture was a rare sequel in this country and common in America it would appear to be possible that the disease existed in two varieties.

SECTION OF EPIDEMIOLOGY AND STATE MEDICINE.

A MEETING of this section was held on May 11th, Dr. R. J. REECE, the President, being in the chair.

Sir WILLIAM HAMER read a paper entitled *The Ultraviolet Viruses Considered from an Epidemiological Point of View.*

He said that the modern history of the subject dated from Buchner's demonstration in 1897 of an intracellular enzyme in the yeast cell, and pointed out that the germs of the bacteriologist might perhaps assume importance in disease mainly by reason of their being able under certain conditions to live in symbiosis with the generally speaking more deadly though more minute ultraviolet living particles. There were, in fact, important inter-relationships

¹ Guy's Hospital Gazette, 1923, xxxvii., 136.
² Ibid., 1921, xxxv., 292.

between the ultravisible germs and the bacteria. These had been compared to those between man and the tools he worked with; or alternatively to the partnership, on a far vaster though probably less important scale, between alga and fungus connoted by the term lichen. Two questions had to be considered: (1) were germs hitherto regarded as causal really primarily concerned with fermentations and with diseases, or merely concomitants—i.e., associated organisms; (2) what was the status, qua organisation, of the ultra-microscopic "enzymes"? In dealing with the first question, the speaker referred to Lord Lister's classical researches on the souring of milk, and quoted the remark that "it is far from impossible that there may exist ultra-microscopic organisms, as real, as distinct in structure, and as potent in their effects as is the *Bacterium lactis*." In these words Lord Lister remarkably anticipated the results of later research. He saw as in a glass darkly the phenomena now familiarly described as those of "sporting" or "mutation" in bacteria, and clearly discerned that ultra-visible particles might play a part in these. Passing to the second question, Sir William Hamer said that the experimental results suggested that to each germ must be assigned a very complex constitution qua enzymes; one enzyme might be represented by numerous particles in a condition of great activity and apt for rapid multiplication; another might be poorly represented by particles which were in an inactive or dormant condition. He outlined the present state of opinion respecting the physico-chemical status of catalysts and enzymes, and considered that it would simplify things if we boldly declared that many "organic catalysts" were really living organisms. He referred with approval to the late Prof. Minchin's speculations regarding the simplest forms of life and their origin. An outstanding difficulty of the epidemiologist, confronted with all the later developments of the germ theory, was that of explaining persistency of type in epidemic disease—persistency such as that displayed, for example, by measles or small-pox. In the case of ultravisible germs of epidemic disease, it might be that, while variability of type was favoured by association of the primary ultravisible organism with various satellite secondary invaders, there was an inevitable return, at appropriate intervals, to phases of influence which again and again repeated themselves. Just as syngamy prevented a species from breaking up into strains, so some equilibration between a primary influence and secondary influences encountered in the bodies of the hosts might bring about major waves of epidemic disease. De Vries had hinted at something of this kind in his "periodic mutations" of the higher plants, and analogous phenomena would at once suggest themselves to all those who had followed up Creighton's teaching with regard to influenza, scarlet fever, and diphtheria.

The paper was discussed by the PRESIDENT, Dr. J. A. ARKWRIGHT, Dr. W. MAIR, Dr. R. DUDFIELD, Dr. J. C. McVAIL, Dr. MAJOR GREENWOOD, and Dr. W. BUTLER.

LIVERPOOL MEDICAL INSTITUTION.

A MEETING was held on April 26th. Prof. J. HILL ABRAM, the President, being in the chair.

Mr. J. ST. GEORGE WILSON read a note on

Broncho-pneumonia in a Stillborn Fetus, Associated with Maternal Death.

The mother, aged 49, was a 14-para; all previous labours normal. The membranes ruptured 30 hours before onset of labour. The first stage occupied three hours. Forceps extraction failed. As the cord was prolapsed and pulseless the foetus was perforated, but there was still failure to deliver. The mother died five and a half hours after the onset of labour owing to shock. The foetus weighed 4.72 kilos; broncho-pneumonia was demonstrated in both lungs,

streptococci were found in the alveoli and cultured from the spleen. The reaction in the lungs was so marked that the inference drawn was that pneumonia commenced before the onset of labour, and it was surmised, in the absence of post-mortem examination, that foetal infection was a contributory cause, if not the sole cause, of the sudden death of the mother.—Dr. NORMAN B. CAPON stated that caution was necessary in assuming that micro-organisms found in a foetus which had died during labour were responsible for any pathological lesion discovered. This was especially true when perforation had been performed.

Mr. F. J. STRONG HEANEY read a short paper on

Cystoscopy and Pyelography.

He briefly reviewed the present position of cystoscopy and pyelography in the diagnosis of diseases of the bladder, ureters, and kidneys. He showed a series of lantern slides exemplifying the following lessons: 1. Cystoscopy by itself excludes the bladder and localises one or other kidney as the active septic focus in certain cases of chronic pyuria. 2. In the absence of tubercle bacilli in the urine cystoscopic examination in conjunction with clinical signs enables one to make a definite diagnosis of tuberculous kidney. 3. The appearance at the ureteric orifice in cases of intramural ureteral calculus alters when the stone remains a considerable time in situ. 4. In some cases of hydronephrosis it is not possible to demonstrate the condition by aspiration, whereas a pyelogram may successfully overcome the difficulties of diagnosis. 5. In cases of obstruction the appearances of the ureterogram or pyelogram vary according to the level of the obstruction. 6. A ureterogram differentiates between a phlebolith or mesenteric gland and a ureteral calculus. 7. The normal pyelogram enables one to exclude the possibility of a kidney condition in favour of other intra-abdominal lesions.

Dr. J. MURRAY BLIGH read a paper on Unexpected Death in Children. He discussed in particular its relation to lymphatism and the clinical signs indicative of this condition.

ROYAL MEDICAL BENEVOLENT FUND.

At a recent meeting of the Committee 25 cases were considered and £250 voted to 20 applicants. The following is a summary of some of the cases relieved:—

Daughter, aged 19, of M.D. Durh. who practised in Staffordshire and died in 1917. Applicant is a probation nurse at £40 per annum, but owing to a bad illness and an operation for appendicitis is unable to continue work until fully recovered. She asks for help towards paying convalescent home charges as her mother is unable to meet the expense incurred. Voted £5.

Widow, aged 37, of M.B. Vict. who practised in Manchester and died in 1914. Applicant has been able to support herself and daughter, aged 14, up to the present time, but she had an illness which increased expenses and also prevented her from earning. During the last 12 months she earned £100 by painting. Applicant is asking for a grant towards her daughter's schooling as she is in need of more advanced tuition. The Committee voted her a small grant to render her eligible for education help from the Royal Medical Benevolent Fund Guild.

Daughter, aged 53, of M.R.C.S. Eng. who practised in Manchester and died in 1876. She is a temporary clerk, but owing to illness has contracted debts and asks the Fund to help with her expenses. Voted £6.

Surgeon, aged 79, who was a house surgeon at a hospital in Wales for 12 years. He came to London during the coal strike and failed to secure an appointment. Stricken with paralysis he and his wife had to live on £100 they had in hand and then had to sell their belongings to enable them to exist. His wife is unable to earn anything owing to eye trouble and recently underwent an operation at Moorfields and has to be led about. The sole income is the applicant's Old Age Pension and £26 allowed by the Fund, and the R.M.B.F. Guild have supplied clothes.

Daughter, aged 43, of L.R.C.P. Lond. who practised in London and died in 1901. Has phthisis and is not strong. A friend at one time made her an allowance but this has now ceased. She had a post as lady help but has had to give this up and go into a sanatorium and asks the Fund to help with expenses. Voted £15.

Subscriptions may be sent to the Hon. Treasurer, Sir Charters Symonds, K.B.E., M.S., at 11, Chandos-street, Cavendish-square, London, W. 1.

Reviews and Notices of Books.

ENDOCRINOLOGY AND METABOLISM.

Presented in their Scientific and Practical Clinical Aspects. By 98 Contributors. Edited by LEWELLYS F. BARKER, M.D. (Toronto), LL.D. (McGill). In five volumes, totalling 4770 pages. London and New York: D. Appleton and Co. 1922. £12.

WHEN von Noorden's great treatise on Metabolism and Practical Medicine was made available to English readers in 1907, it must have seemed unlikely to many of them that the latter part of the title would ever be justified, and yet the change which has since come over text-books in all branches of medicine bears evidence to the influence of that work and to its author's intuition. So, too, we believe that Prof. Lewellys Barker is correct in his surmise that the time is ripe 15 years later for the publication in reasonable compass of all the essential facts that bear upon metabolism and the internal secretions in health and disease. The editor and his associates have succeeded in so balancing their materials—*anatomical, physiological, chemical, experimental, pathological, and clinical*—as to have produced a book of value both to research workers and actual medical practitioners, and that within a readable compass of four volumes, for the fifth is taken up with references and indexes. The writers of the several articles are all competent workers in the subjects allotted to them; they have exercised sound critical judgment in the sifting of statements and claims, and they have presented a valuable compendium of established facts in which mere speculation finds little place. The clinical descriptions of disease which accompany the physiological and pathological summaries are a new feature in medical literature. The medical student has been trained in his preliminary scientific and in his hospital education to bring his physiological conceptions to the bedside, but has found the difficulty almost insurmountable of carrying physiological thought with him into actual practice. Hitherto, it has been difficult for the busy practitioner to correlate the advances in physiology with applied medicine and surgery. In these volumes the correlation lies ready to his hand.

Volume I. contains general considerations regarding endocrinology, including an historical survey of the subject, and deals with the thyroid and parathyroid glands and the hypophysis cerebri. Volume II. treats of the pineal, suprarenal, and thymus glands, the gonads, the mammary glands, placenta, spleen, liver, pancreas, salivary glands, stomach, and intestines, all considered as endocrine organs with possible internal secretions. The special anomalies of gigantism, dwarfism, and infantilism are described, and the inter-relationships of endocrine glands considered. Volumes III. and IV. are devoted to normal and abnormal metabolism. Volume V. contains, it has been said, the general index and bibliography.

Among the most interesting of the sections are those on the physiology and experimental pathology of the thyroid gland by Swale Vincent, and on hypothyroidism by Nelson W. Janney. In the first volume the whole of Section III., which deals with the parathyroid glands and particularly Lewellys Barker's able survey of the clinical syndromes due to disorders of these glands, are worthy of the attention of clinicians. In the second volume Benson A. Cohoe on clinical syndromes due to suprarenal diseases, and R. G. Hoskins on the inter-relation of the endocrine organs are of especial interest; and in Volume III. Ringer and Baumann on the carbohydrates and their metabolism and John R. Murlin on normal processes of energy metabolism stand out. In Volume IV. D. D. van Slyke writes on acidosis, W. T. Longcope and G. M. Mackenzie on hypersensitiveness and protein intoxication, and Rollin T. Woodyatt on the pathological metabolism of diabetes mellitus. Two curiously divergent accounts of pellagra by Ward J.

MacNeal and E. V. McCollum serve to illustrate both the uncertainty of our knowledge and the impartial attitude of the contributors.

It has been well said that endocrinology needs a leadership willing to admit the magnitude of its shortcomings. The compendium before us establishes such a leadership with true scientific impartiality. The survey presented will help the physician to distinguish fact from fancy in a field in which the imagination has recently been allowed free play. The sifting has been rigorous, and some readers may be disappointed to find how many of the advantages claimed for "organotherapeutic" preparations rest upon no solid foundation either clinical or experimental. So widespread is the faith in promiscuous endocrine therapy that the negative conclusions of some of the workers in this field deserve quotation. John T. Halsey submits to critical examination the administration for medical purposes of various preparations of animal origin in his chapter on organo-therapy and hormone-therapy. He admits the value of thyroid preparations in cretinism, myxœdema, and obesity, but is unconvinced by many of the claims made as regards mental diseases, epilepsy, deafness, asthma, nephritis, and blood dyscrasias. Even in skin diseases he regards the use of thyroid extract as of only limited value. Concerning parathyroid, he says "there are reports of its more or less successful use in tetany, paralysis agitans, eclampsia, epilepsy, and chorea, but it is only in the treatment of tetany that parathyroid therapy rests on a firm and rational basis." He is doubtful whether the anterior portion of the pituitary has yielded results justifying the enthusiasm of its advocates. Suprarenal extract has given brilliant results in the relief of asthma, and, of course, is invaluable as a local vaso-constrictor in ophthalmic and nasal operations, but further than this he not inclined to go. Halsey has never seen any effects, good or bad, follow the administration of parathyroid preparations in paralysis agitans. As to testicular extracts given by mouth, the evidence shows them at best merely of suggestive therapeutic value.

G. N. Stewart, writing on the significance of the suprarenal glands, holds that there is no foundation for a supposed rôle of epinephrin in reactions associated with the expression of the emotions. The same chapter contains the observation, "the elaborate theory of the reciprocal relations of the endocrine organs originated by Eppinger, Falta, and Rudinger gains no support from such experimental observations as have been made either upon the epinephrin store or the epinephrin output." Hoskins, writing on the relation of the suprarenal glands to circulation, mentions the general impression that epinephrin acts as a vaso-constrictor and raises blood pressure, and observes that vaso-dilatation is a characteristic, and, perhaps, the most significant phase of the vaso-motor reaction to epinephrin. But, in summing up, he concludes that "the most that can be definitely said at the present time is that epinephrin in neither a vaso-constrictor nor a vaso-dilator substance, generally speaking, but is either, depending upon the dosage employed, the organ involved, and the condition of the organism as a whole." He protests that in many pharmacological experiments with epinephrin concentrations grossly out of proportion to those to which the tissues are exposed under normal conditions were employed. The entire pharmacology of epinephrin demands reinvestigation. The same author comes to the conclusion that there is little or no reliable evidence that the thymus has any true endocrine function. A. S. Warthin gives it as his experience that the majority of cases of diabetes (all adult cases and a few young adults) present a chronic pancreatitis. He is, moreover, strongly of the opinion that latent syphilis is one of the most important causes of chronic pancreatitis.

Hoskins, referring to the lack of proof that the various endocrine organs stand in intimate functional relationship with each other, finds facile theorising to have been indulged in by numerous uncritical

writers. A diagnosis of "pluriglandular dystrophy" or "pluriglandular syndrome" is more often mere camouflage for ignorance. C. E. de M. Sajous remarks, "If the general practitioner will take a personal interest in accurate diagnosis and carefully controlled therapy of the diseases of endocrine origin, he will give help that is much needed at this time." Practical medicine stands in need of iconoclasm of this sort, but it must not be supposed that the bulk of this book consists of denial or disproof. There remains an enormous mass of new facts which have passed the test of critical examination, and a further collection of observations which, though still unproven, are suggestive. Certain modern work is especially well set out here. Lewellys Barker's chapter on the clinical syndromes due to disorders of the parathyroid glands summarises most readably all the modern observations on this subject. J. P. Simonds's survey of the pathological anatomy and histology of the hypophysis is remarkably clear and includes the original observations of the writer. Philip B. Hawk contributes a chapter on water as a dietary constituent. He has proved by careful experiment that the evil effects of drinking water during meals are not only hypothetical but non-existent. His conclusion is that it is better to drink water with meals than between meals, since it aids gastric digestion if taken with well-masticated food. The idea that water dilutes the gastric juice and hinders digestion seems to be quite unfounded. Woodyatt deals briefly and succinctly with the dietetic management of diabetes. His method of calculating the "optimal" caloric diets is one of the best we have seen, particularly his formula for the proportion of fats to carbohydrate and protein. "Insulin" had not been introduced when these volumes were published.

The whole is a work which throws light as much on the common diseases of medical practice as on the obscure, and goes a long way towards the incorporation of experimental medicine and physiology in the everyday practice of physic. The book is admirably printed and full of beautiful illustrations.

PSYCHOLOGY AND PSYCHOTHERAPY.

The Mind and What we Ought to Know About It. The People's League of Health Lectures. Oxford Medical Publications. London: Hodder and Stoughton, Ltd. 1923. Pp. 252. 6s.

THIS series of essays by leading medical men opens with a stimulating paper by Dr. Bernhard Hart on Primitive Instincts, in which he sets his readers to study their conflicts and prejudices; then it passes on to what may be termed the old psychology. Dr. R. H. Cole casts aside Prof. Sherrington's belief in the incommensurable nature of the worlds of body and mind in telling us that "these two aspects of the reflex arc—the mental and the physical—are practically identical," so one need not interpret as a cry of despair his view that "a mental state connotes some nervous change in the individual, and without a proper grasp of this connection I can conceive no rational explanation of the workings of the mind." Yet to explain the mental state, let us say, of Mr. De Valera in terms of nervous change would seem a hopeless task.

One is surprised to find Dr. Rows discussing memory with no hint of the transfer of psychological interest to the subject of forgetting, and the light which that throws upon mental processes. Habit and Adaptation, and Fatigue and Sleep, are quite simply handled by Dr. Macnamara and Sir Robert Armstrong-Jones respectively, though the latter's summing up is not clear. "Remember that it is not the subjective feeling of fatigue that you feel, although it is present, but it is the objective symptoms that come on afterwards that are felt, and when they come on they take longer to clear up," he says. This is rather bewildering; and surely Sir Robert Armstrong-Jones does not believe the story of the three boys who killed themselves by keeping awake. Sir Frederick Mott describes the reciprocal

influence of the endocrine glands and mental processes, and, illustrating his thesis by reference to war cases, concludes that "If doctors paid more attention to the mental state of their patients in relation to bodily disorders . . . Coué cult, Christian Science, and other forms of faith-healing would not have laid hold of the popular imagination so deeply." In the whole series the only reference to the work of Freud—and the public interest in his theories of the mind, whether it should be encouraged or not, is undoubted—is Sir Frederick Mott's bewildering allusion to a "Freudian doctrine" that "all dreams with fear are related to forgotten sexual experiences causing a mental wound"; surely this is not derived from the study of Freudian writers. Dr. W. A. Potts's lecture on Crime and Delinquency is a description of modern views and methods with a too brief account of the work already being done at Birmingham in the rational treatment of the criminal. This is a practical subject on which the public should be enlightened, and the lecture is in itself sufficient to justify the book. Dr. Tredgold, in his discussion of Mental Deficiency, is under the disadvantage of being unable to formulate proposals, though he points out the direction in which action might be taken and gives a general account of the varieties and causes of mental deficiency.

To put a subject like this before the public is inevitably a difficult task, but one trusts that the authoritative title of the book is not meant to be exclusive; there is quite a lot more we ought to know.

Conditions of Nervous Anxiety and their Treatment. By Dr. WILHELM STEKEL, Vienna. Authorised translation by ROSALIE GABLER. London: Kegan Paul. 1923. Pp. 435. 25s.

OF a series of seven volumes on "Disturbances of the Impulses and the Emotions" by this prolific writer the present volume is the first to be translated into English. Dr. Stekel says in the preface that the material could have been collected only on the basis of a private practice and that as a specialist he now seldom sees the same kind of material. This paradox is understood when we read his description of the anxiety attack and its equivalents, which include palpitation, paroxysmal tachycardia, nervous dyspepsia, pseudo-angina, hay fever, attacks of night sweating, vomiting and headache, migraine, faintness, and collapse, all of these being common in general practice. He maintains that every neurosis is caused by a psychic conflict, and denies the existence of the "actual neuroses" that Freud attributes to disturbance of sexual life, placing them beyond the sphere of psychotherapy. (It is surely a translator's error when we are told that Freud ascribes them to "sexual abuses.") He also gives examples to show that the anxiety attack can occur without sexual foundation. In the wealth of his clinical material Stekel stands almost alone, and if his facts are accepted his unreserved discussion of sexual details is justified. Especially interesting is his analysis of a "heart neurosis" (chap. xvii.), when he gives the patient's anamnesis and remarks that the doctor who listens to it "will come to the conclusion that cares, anxiety, worry, over-exertion and over-work are accountable for the terrors of the neurosis;" then follows an account of the analysis, which gave a picture totally different from that of the simple anamnesis. His analyses are not always profound, nor are his theoretical dissertations, but his cases are described with such fullness that the conclusions are often inevitable if his observations are accepted. But there is often a dogmatic—not to say slapdash—quality about the dicta which puts the careful reader on his guard. A case of gastric disturbance with vertigo is diagnosed "sausage poisoning" for the reason that "After a detailed inquiry she admitted having eaten a thin slice of sausage the previous evening, of which all the members of the household had partaken without harm" (p. 97); and it would be hard to crowd into a few lines more material for disputation than is found in the statement—lonely and unsupported—

that "the root of all desire to know is to be found in curiosity about sex, and a premature enlightenment of the children would certainly be injurious to the development of humanity" (p. 443). This defect is more regrettable because there is so much valuable clinical material and experiment recorded in the book, with practical observation that seems well supported; the author's remarks on epilepsy, for example, are cautious and at the same time original and stimulating, and are accompanied by a sufficiency of evidence.

The translation shows many blemishes. Concerning sufferers from heart neuroses we read: "Or else they have 'incipient calcination' which patients rightly look upon as a death sentence." And no wonder! Cyclothymia appears in three different spellings; "Jackson-epilepsy," "sinew reflex" for knee-jerk, and other departures from orthodox terminology are likely to receive criticism. But in spite of many defects the book is a useful addition to clinical psycho-pathology.

JOURNALS.

QUARTERLY JOURNAL OF MEDICINE.—The April number contains the following articles: The Sequelæ of Epidemic Encephalitis in Childhood, with Notes on the Prognosis as regards Complete Recovery, by Grace H. Anderson. This paper is based upon an examination of 38 cases in hospital in Glasgow. The chief points upon which stress is laid are the frequent occurrence of night wakefulness and excitability, and various psychical disturbances. Mental impairment was noticed chiefly in younger children and changes in disposition, invariably for the worse, in the older. The most troublesome habits were spitting and hyperpnoic breathing, for which no treatment was found effective.—The Cholesterol Content of the Blood in Anæmia, and its Relation to Splenic Function, by William MacAdam and Cecilia Shiskin. The cholesterol blood content was determined for varying periods in three cases of splenectomy performed for hæmolytic jaundice, and in one case of splenectomy for splenic anæmia. Twenty-five cases of anæmia of varying types were subjected to a similar investigation. It was found that after splenectomy an increase occurred in the cholesterol blood plasma content, whereas the excessive fragility of the red cells persisted in cases of hæmolytic jaundice. The relationship of the hypercholesterolaemia to the cessation of splenic function is undetermined. In the anæmias a slight degree of hypocholesterolaemia was found.—Quinidine in the Treatment of Auricular Fibrillation, by Archibald E. Clark-Kennedy. This contribution is based upon the results obtained by treating 45 unselected cases of auricular fibrillation with quinidine sulphate. In 82 per cent. a normal cardiac rhythm was restored. A preliminary course of treatment with digitalis was invariably given, and when no further improvement could be obtained with this drug quinidine was substituted. The usual dose was 5 gr. six hourly for 12 doses, the amount being gradually increased until "severe toxic symptoms or signs and symptoms of heart failure were observed." The simultaneous administration of digitalis and quinidine is not recommended. One fatality due to the quinidine occurred, in this instance there was no embolus, but the drug presumably had a toxic effect upon the myocardium. The rheumatic cases were most favourably affected by the treatment.—Variations in the Threshold in Renal Glycosuria, by George Graham. In renal glycosuria sugar is always said to be present in the urine, and the level of blood-sugar before and after a carbohydrate meal falls within the normal limits of variation. The author describes here a new type of renal glycosuria in which sugar is not always present in the urine, but only occurs when carbohydrates are eaten. The blood-sugar curve, however, is normal. Four examples of this class are recorded, which are considered to form a link between normal individuals and those affected with typical renal glycosuria.—Observa-

tions with the Hæmatocrit Volume-colour Index, by George Rossdale. The hæmatocrit is an instrument for recording the red-cell volume of the blood. The results obtained with whole blood were more accurate than when citrated blood was used. The volume-colour index is obtained by dividing the hæmoglobin percentage by the hæmatocrit percentage; it is thought to be of more value than the colour index, in certain cases in which there is an alteration in the volume of the red cells.—Endocarditis Lenta, by H. J. Starling. The chronic variety of infective endocarditis is considered in this article. The clinical aspects are fully discussed: they are based upon observations made upon 30 soldiers under treatment in 1917-19, and upon 22 discharged soldiers admitted to hospital from 1919-22. The infection is thought to be a primary one of the endocardium, due to a streptococcus of low virulence. Two excellent plates of the post-mortem macroscopical appearances of the heart are included in the journal.

JOURNAL OF INDUSTRIAL HYGIENE. March and April, 1923.—The first article, which is the second report of the Commission on Resuscitation from Carbon Monoxide Asphyxia, is contributed by C. K. Drinker and W. B. Cannon. It deals with the present practice in resuscitation from poisoning by illuminating gas, and the eventual course of patients poisoned by carbon monoxide. The authors report that gas companies in America are providing means for resuscitation; the Schäfer method is most advocated. The lungmotor and pulmotor are used, but are not strongly recommended. Most of the serious cases are removed to hospital, where records show a death-rate of 14.5 per cent. of cases admitted. The patients have a high average pulse-rate, and in 27.8 per cent. undue moisture in the lungs. The Commission is undertaking a series of experiments on the problem and will offer recommendations later.—An article on Ventilation in English Factories and Workshops in Hot Weather is provided by T. C. Angus, who has worked with Dr. Leonard Hill. He advocates the use of jet tubes for causing air movements. A stream of air driven at high velocity is passed through a jet well over the heads of the workers; its force is sufficient to set in motion a great volume of air around its path. The results obtained are illustrated by diagrams which are based on tracing the movements by smoke clouds.—Messrs. F. P. Underhill and B. R. Harris discuss the Influence of Benzol upon Certain Aspects of Metabolism. From laboratory experiments upon animals they conclude that benzol acts not only on the blood elements, but exerts a katabolic influence on body tissues as a whole. This influence is manifested by a sharp rise in creatine and total nitrogen, within a very short period after subcutaneous injection.

In the April number the therapeutic use and toxicity of picric acid is dealt with by C. T. Pack. Picric acid, trinitrophenol, is distinctly less toxic than trinitrotoluene. Two cases of dermatitis following upon the application of picric acid for burns are described. The dermatitis is ascribed to the employment of alcohol as a solvent for picric acid, which causes increased absorption. The resulting dermatitis resembles that caused by trinitrotoluene.—R. Williamson reports investigations into the effect of aniline-black dyeing on factory workers. Three yarn-dyeing works were visited and the workers examined. Changes in the blood were carefully estimated and are given in detail. Aniline was found to be associated with anæmia, distinguished by a decrease in total hæmoglobin, a decrease in the number of red cells, a lower colour-index, but with little alteration in the leucocyte count or in the differential count.—J. S. Owens describes his Jet Dust Counting Apparatus, which is probably the best method for estimating atmospheric dust yet produced. In it a given sample of air is made to impinge suddenly upon a cover-slip. The device ensures that any particles in the air adhere to the cover-slip, which can then be examined under the microscope. The mechanism of the apparatus is clearly illustrated, and microphotographs are given of results obtained by its use.

THE LANCET.

LONDON: SATURDAY, MAY 19, 1923.

THE MANAGEMENT OF PERITONITIS.

AT a recent meeting of the Hunterian Society, Mr. H. W. CARSON chose as a subject for the annual oration the evolution of the treatment of septic peritonitis. In this interesting survey, an abstract of which appears elsewhere (p. 1035), the slow advance of knowledge is strikingly shown. The painful emergence of truth from the realms of superstitious belief, hampered by authoritative pronouncements based upon faulty deductions from a too limited trial of newly advocated methods, provides a lesson which may well be taken to heart. That great master, DUPUYTREN, because of an unfortunate result in a single case, declared that the opening of localised abdominal abscesses should never be undertaken, and even SYME lacked the vision to perceive that he had evolved a general principle, and that results might be obtained in abdominal surgery as brilliant as those he was already getting in operations upon other regions of the body, by insistence on the most careful personal cleanliness. It was left for LAWSON TAIT to further the cause of abdominal surgery by establishing the first crude system of aseptic surgery. The operative treatment of peritonitis therefore had its beginning not quite fifty years ago, whilst all the important knowledge dates back for scarcely twenty years.

During this time certain problems have been solved, but others have remained subjects of controversy. The outstanding established facts are the great powers of resistance to infection of healthy peritoneum, the ability of this membrane to localise the disease when the source of infection has been timely removed, the existence of a critical point which corresponds with the absorption of a fatal dose of toxin, the tendency for the infection to travel upwards towards the diaphragm, where absorptive activity is greater than in any other region of the abdomen. The disputed point is really the measure of surgical activity which is indicated at different stages of the disease. All are agreed, however, that the chances of success are immeasurably greater when earlier treatment can be instituted. During the first few hours the only really essential thing is to remove the source of infection. Generally speaking, the earlier an inflamed appendix is removed or a perforation sutured, the greater the likelihood of a happy issue. But even here the surgeon can be too precipitate, for a patient whose perforated gastric ulcer was sutured within an hour of the catastrophe occurring has succumbed to the operative intensification of the extreme initial shock from which he was suffering, a condition of depression which usually passes off in two or three hours. A point which is much debated is the advisability or not of draining the peritoneal cavity after the primary source of infection has been dealt with. Very free drainage at one period was universally advocated, but we no longer see three or four tubes protruding from the abdomen of the convalescent patient. The most ardent advocate of drainage will scarcely ever insert more than one, and that into the lowest part of the cavity. But a large group of surgeons main-

tains that even this tube is unnecessary. This school relies solely upon the admittedly almost miraculous natural powers of defence. It is recognised by the advocates of the method that sometimes the process is limited but not eradicated, so that a pelvic abscess may require to be evacuated in one or two weeks' time, but they will not allow that after the removal of the infecting focus the likelihood of diffuse spread of the peritonitis is lessened by the insertion of a tube. The onus of the proof of this declaration should rest upon the advocates of the procedure, and until it is forthcoming the interests of the patient will probably be served better by retaining the drainage-tube, for the dissenters can point to cases where they believe life has been saved only by reopening the abdomen to allow of the exit of accumulating peritoneal exudate. Yet no one will deny that many abdomens may be sewn up with impunity in a way which would have been inconceivable some years ago. Irrigation of the cavity where the inflammatory process is diffuse has been given up by nearly all surgeons. It is impossible to remove the infective material by this means; on the contrary, irrigation forces this material into unattacked regions, prolongs the operation, and damages the peritoneal membrane. MURPHY's advice to "get in quick and get out quicker," is based on a sound policy.

When the inflammatory process is nearing the critical stage or when it appears to be localising itself, the question must be settled whether any surgical intervention at all is right. One school of surgeons strongly advises against any operative measures being taken, for they believe that the opening up of healthy tissue-spaces, and the possible further dissemination of the infective material may just suffice to turn the scale against the patient. Every effort should be made to assist the victim in delimiting the inflammatory process. This object is best achieved by securing absolute rest for the alimentary canal by starvation and the administration of opium, whilst saline is given by the rectal path in as large a quantity as the patient will absorb. Rectal saline is universally recognised as a very valuable measure in combating peritoneal infection, but the administration of opium is regarded as dangerous by some surgeons who, on the contrary, give aperients in small repeated doses. They point out that if in peritonitis the bowels can be got to act, recovery usually follows. But a movement of the bowels is simply an expression of the removal of the inhibitory impulses going to the bowel wall and is in itself a sign of the subsidence of the pathological process. To give opium with the object of abolishing peristalsis is an attempt to ensure for the inflamed area that rest which HILTON emphasised so strongly as necessary. Nevertheless, the greatest care must be taken not to overdose with opium and so substitute one pathological state for another. Pituitary extract, because it is a motor excitant of the bowel, is contra-indicated. It is against the teaching of pathology. Whether operation be carried out or not, the sitting posture has proved itself undoubtedly a valuable adjunct in preventing the spread of peritonitis to the upper dangerous area of the abdomen, so that from the moment when the diagnosis of peritonitis is made the patient should be propped up in this position.

THE VACCINIA VIRUS.

IN all work upon vaccinia and the preparation of vaccine lymph the elimination of the calf has been an end towards which attention has been constantly fixed. Recent studies of the properties of the active

principle of lymph have given reason to hope that this achievement is within measurable distance of being accomplished. The possibility of the propagation of the virus through rabbits' brains has been brought into prominence by A. MARIE,¹ who found that the intracerebral inoculation of this substance causes, in these animals, a form of encephalitis which terminates fatally in four or five days and, further, that it is possible to carry on the passage of such a malady from brain to brain in series. According to MARIE such a new habitat causes an increase in the virulence of the active agent towards the central nervous system, accompanied by a loss of virulence for the skin; ultimately a vaccine was obtained which had lost the power of causing vaccinia, which originally characterised it, but which was very active in causing the characteristic vaccinal form of encephalitis. The subject has been recently taken up with great thoroughness by C. LEVADITI and S. NICOLAU,² who have confirmed and extended the previous observations upon the neurotropic affinities of vaccine virus; their results differ from those already quoted in that even after many cerebral passages, in which it acquires a high degree of virulence towards the central nervous system, the virus still retains its affinity for the skin.

Such a neuro-vaccine, as they call it, consisting of the emulsified brain-substance of rabbits which have succumbed to the cerebral malady after intracranial inoculation, is sterile in so far as ordinary bacteria are concerned, and is still capable of setting up vaccinia when inoculated into the skin of susceptible animals; it does, however, appear somewhat less potent in this respect than the ordinary vaccine which has been cultivated continuously upon the skin (dermo-vaccine). This result is especially seen in the fowl, where the additional interesting fact emerges that although no eruption of vaccine pustules is observed, yet the animal becomes refractory to a subsequent inoculation with the dermo-vaccine. The neuro-vaccine has been used with success upon the human subject, in whom it produces typical vaccinia; an advantage is claimed over the usual calf lymph in that the emulsified brain is entirely free from septic organisms. In further studying the properties of their neuro-vaccine the authors show its affinity for the cutaneous system. When the virus is injected intravenously in the rabbit, an abundant crop of cutaneous pustules occurs, which is especially localised in any region of the skin which has been previously irritated by shaving and pulling out the hairs. They also adduce evidence that the germ localises itself electively in such portions of the body as are developmentally allied to the skin, as being products of the ectoderm, thus bringing the condition within the group of the neurotropic dermatoses which LEVADITI has laboured to establish. His work in this direction we have noticed previously.³ Thus, after intravenous injection, the virus can be detected in the skin, saliva, buccal mucous membrane, mammary glands, and brain; whilst showing little, if any, tendency to remain in mesodermal organs such as the blood, spleen, bone marrow, lymphatic glands, muscles, or kidneys. Previous injury seems to aid this localisation in organs for which the germ has a special affinity. This inter-relationship of the various structures of embryological fraternity is further emphasised by the fact that where the immunity

of one of them is acquired by inoculation a refractory state is simultaneously engendered in the others; the production of a crop of vaccine pustules on the flank of an animal will render its brain resistant to direct inoculation with the virus.

Such immunity would appear to be a localised tissue immunity, since no trace of anti-bodies is to be found in the blood, whilst the brain, in such a case, has the property of destroying the virus when mixed with it. In view of the fact that the immunity in vaccinia is of limited duration, the authors put forward the thesis that this resistance is a property residing locally in the tissues in question, which is developed in them at the time of the original vaccination and which is transmitted from cell to cell, becoming gradually attenuated and worn out as the tissues are constantly renewed. Such an immunity would therefore tend to disappear most quickly from those tissues which reproduce most rapidly. This theory is supported by experimental evidence which is extremely ingenious and interesting, though not, in our view, conclusive.

PSYCHO-PATHOLOGY IN THE CURRICULUM.

ANY proposal to add to the medical curriculum calls for special examination, and Sir GEORGE NEWMAN, in the Memorandum on which we commented in a recent issue, proposes additions which entail considerable encroachment upon the student's already well-filled table of subjects. Particularly in psychology and psycho-pathology does he call for instruction of a kind that has hitherto been almost entirely absent, and the schedule suggested by him—which appears elsewhere in this issue—is supported by his more detailed criticism of present deficiencies. Instruction in the psychoses has not kept pace with the progress of pathological, clinical, and therapeutic methods, and only a minority of the examining bodies include the subject in their examinations. The clinical side of the subject is generally taught in an asylum to which the student pays the visits necessary to procure the certificate of instruction demanded by his examining body; the patients he sees are already in a condition involving certification, and he is left without experience of the perplexing cases of early or doubtful insanity which will form some of his problems in general practice. The institution of the various diplomas in psychological medicine has led to the establishment of instructional courses such as those at Bethlem and the newly-opened Maudsley Hospital, so that post-graduate work on the subject is now available. In Birmingham, which already leads the way in the practical application of psycho-pathology to the study of the delinquent, a department of clinical psycho-pathology is now attached to the medical school of the University, and we may expect soon to see the subject included in the ordinary curriculum. From this example we may judge that the needs of the situation are already on the way to recognition.

Some of the scheduled proposals concerning the psychoses might be criticised on the ground that the practitioner is commonly relieved of the responsibility of treating patients when they have reached the stage of being certified, but the case of the psycho-neuroses is in strong contrast. There are few institutions which will receive, on what might be called "hospital terms," the sufferers from those psycho-neurotic

Annotations.

"Ne quid nimis."

YOUTH AND THE RACE.

ENCOURAGED by Dr. Addison, then Minister of Health, the National Council of Public Morals resolved in 1920 to investigate the problem of sex education in its relation to the care and training of adolescents. Dr. Addison was of opinion that parents generally had either shirked their duty to their children in this matter or were afraid to do it, while it was difficult for teachers to take their place. The National Council referred the consideration under six heads to a Commission of Inquiry, including such representative medical men and women as the late Sir G. S. Woodhead, Dr. Mary Scharlieb, the late Dr. J. W. Ballantyne, Dr. A. K. Chalmers, Dr. Eric Pritchard, and Dr. Charles Porter. The inquiry narrowed itself down to the development and education of young citizens for worthy parenthood, and even with this limited reference the volume of important and closely reasoned evidence is enough to fill a substantial book. Competent and authoritative witnesses representing psychology, education, and medicine, assisted the inquiry, and the report of the Commission is contained within the 26 opening pages of a volume,¹ the bulk of which contains the verbatim evidence. The Commission was soon satisfied by the evidence laid before it that instruction in regard to sex could not be shirked with due regard to the moral safety and welfare of youth, and that such instruction should be considered not as an irksome duty but as a privilege. Dr. Lyttelton put the age of 9 years as the time when boys should be perfectly able to understand the facts of maternity, and Miss Edith Cooper showed as the result of instructing thousands of mothers in Birmingham that the more precisely detailed teaching of later years should be prepared for in the infant schools. The Commission records its conviction that instruction in sex matters should be given whenever curiosity in regard to them appears or when there is any indication of the formation of bad habits. At the same time it recognised the serious mistake of isolating sex instruction from moral education generally and thereby giving undue emphasis to it. Chastity, the report wisely lays down, should be treated as only one element in the good life, and the child should not be led to take a greater interest in this than in any of the other functions of life. As is so often the case in the reports of commissions, the notes of reservation are instructive in showing the points on which interest specially centred. A group of five members regard it as urgently necessary for the State, through the Ministry of Education, to ensure that every boy and girl leaving school should receive definite biological and physiological instruction about the facts underlying sex and the sex relationships, the first step to attain this being to secure a supply of teachers equipped with the necessary knowledge. Another group of six members regard as desirable the prohibition of the sale of alcoholic liquors of whatever kind to young people under the age of 21, in order to diminish the risk of sexual excitement resulting from intoxication by beer. Dr. Chalmers registered his personal feeling that the report laid insufficient stress on the physiological inhibitions of infancy and childhood, which may so readily become a pathway to the exercise of reasoned choice in later life. To him the basis of education is laid when the intelligent mother teaches her infant to exercise little acts of self-control. The volume is worth having for these 26 opening pages in themselves, but its chief value resides in the store of wise experience contained in the minutes of evidence.

¹ Youth and the Race. The Development and Education of Young Citizens for Worthy Parenthood (being the fourth report of, and the chief evidence taken by the National Birth-rate Commission, 1920 to 1923). Sir James Marchant, K.B.E., LL.D., Secretary. London: Kegan, Paul, Trench, Trübner and Co. 1923. Pp. 378. 15s.

disorders which, as Sir GEORGE NEWMAN says, are responsible for much misery and invalidity. Nearly two and a half centuries ago SYDENHAM wrote, in his Epistolary Dissertation to Dr. Cole: "Of all chronic diseases hysteria—unless I err—is the commonest," and in this Memorandum almost the same view, though with an important addition, is expressed in modern terminology: "Pure psycho-neuroses, or bodily derangements coloured by a psycho-neurotic element, will provide the general practitioner of medicine with a very large proportion of his most difficult cases. Yet at present we teach the student nothing of the make-up of the normal mind; we give him no help in separating the false from the true in the wordy strife as to the nature, ætiology, and treatment of psycho-neuroses." This explicit and authoritative statement crystallises a body of opinion which has been steadily growing since the many thousands of cases of "war neuroses" revealed a defect in our medical training which necessitated the establishment by Government departments of centres—first at Maghull and later at Tooting—where men already qualified were taught the elements of psychopathology. The interest then roused has found a further field in the neurotic disorders of civil life, for experience has shown that the same mental processes are involved in what was erroneously called "shell-shock" and in the "nervous breakdowns" in times of peace. And, just as in time of war the maintenance of the health and efficiency of the soldier made imperative a training in this subject, so the chief medical officer of the Ministry of Health finds it imperative that for the maintenance of a high degree of mental health and capacity in the population the general practitioner should have received instruction in the ætiology, symptoms, diagnosis, treatment, and prognosis of the morbid mental states most commonly met in general practice.

Yet psycho-pathology remains a neglected child of medicine—it sometimes seems almost an illegitimate one, and unless an individual member of the teaching staff chances to take a live interest in the subject the student will leave hospital knowing not even the meaning of anxiety neurosis or obsessional state; these and other common disorders will remain, as before, unrecognised and untreated. Only one or two London hospitals provide systematic lectures, and little is heard of out-patient departments where students would be sure of receiving the necessary clinical instruction. On the other hand, the recent progress of both interest and knowledge in regard to the psycho-neuroses has been rapid; we may regard Sir GEORGE NEWMAN'S outspoken formulation of the position as in some degree an indication, even a result, of that progress, as well as an expression of the growing realisation of the clinical opportunities afforded by the psycho-pathological material to be found in our hospitals and in private practice.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—A further series of post-graduate lectures, open to members of the profession, will be given in the house of the Royal Society of Medicine, 1, Wimpole-street, London, W. 1, during the session. The opening lecture on Wednesday, May 30th, at 5.30 P.M., will be given by Mr. Ernest Clarke on Tips in Ophthalmology for the General Practitioner, and others will follow by Mr. R. A. Hendry, Mr. James Berry, Sir Sydney Russell-Wells, Sir Henry Gauvain, Mr. Harold Chapple, and Mr. H. S. Souttar. A course of eight practical lecture-demonstrations on Gastro-Intestinal Diseases of Children, &c., will be given by Sir William Bayliss, Dr. Bernard Myers, and Mr. E. T. C. Milligan at the Children's Clinic, Western General Dispensary, Cosway-street, London, N.W. 1, from June 11th to July 5th, inclusive, at 5 P.M. A complete syllabus of either course will be forwarded on application to the Secretary to the Fellowship of Medicine, 1, Wimpole-street, London, W. 1.

the Socratic method being singularly productive where those who questioned were as competent as those who were to answer the questions. The preface foreshadows the publication later on in the year of the results of a further scientific investigation into the educational value of the cinematograph, conducted by expert physiologists under the chairmanship of Prof. C. E. Spearman.

OCTO-CENTENARY OF ST. BARTHOLOMEW'S.

Wolmer, a cripple, who had sat for 30 years in St. Paul's Cathedral asking for alms, in 1123 was borne in a basket before the altar of St. Bartholomew's and there stretched out his limbs and walked out well. The late Sir Norman Moore, historian of St. Bartholomew's, who tells this story, adds that in the same year Rahere began his priory, and founded the hospital upon a bed of gravel on the highest part of the open space of Smithfield—a site well and truly chosen. At the solemnity just 800 years later, which will open the celebrations at noon on Tuesday, June 5th, there will be a representation of the episode of Rahere returning from his pilgrimage to Rome and meeting Richard Belmeis, Bishop of London, through whose instrumentality Henry, King of the English, granted land upon which the hospital was built. The second episode will record the presentation, by King Henry VIII. on June 23rd, 1544, of a charter to the Lord Mayor and Commonalty of the citizens of London, restoring to the hospital the lands alienated on the dissolution of the monasteries. The provisional programme of celebrations which has now been issued gives the events which will occupy the remainder of the week. On Tuesday the Lord Mayor will entertain the delegates to luncheon at the Mansion House, and at 3 o'clock that afternoon they will present addresses to the Prince of Wales, as President of the Hospital, at the Guildhall. Bartholomew Fair will be opened at 1 P.M. on Wednesday by the Lord Mayor, and on that and the following afternoon tableaux by the Royal Academicians, Mr. Charles Ricketts, Mr. Charles Sims, Mr. S. T. Solomon, and Mr. George Harcourt, with music arranged by Sir Alexander Mackenzie, illustrative of events in the history of the hospital, will be shown in the Great Hall. On Wednesday afternoon there will be a reception at the Royal College of Surgeons, and old students will dine together at Merchant Taylors' Hall at 7 P.M. On Thursday evening a conversation will be held in the hospital and medical college. On Saturday afternoon a cricket match, Past v. Present, will be played on the hospital ground at Winchmore Hill, and the League of St. Bartholomew's Nurses will be at home to delegates. An exhibition of historical and scientific interest is to be held during the week within the hospital precincts.

THE VOLUME OF THE HEART BEAT IN MAN.

THE volume of blood put out by the heart at each beat is one of the most fundamental quantities in physiology, and among the most difficult to measure. The ancients speculated brightly with imaginary premises; when they found that their calculations from the quantity of blood in the body and the rate of the heart beat led them to the conclusion that the whole blood must go round the body several times a day they were frightened at their extravagance and compromised with the suggestion that it probably really went round twice in sympathy with the ebb and flow of the tides.¹ We realise now that blood pours along the aorta at a rate which few bath taps could equal, though we are still far from understanding the variations of rate and its smaller niceties as we should like to. The chief difficulty is that the available methods are indirect and become less and less satisfactory as the experience and skill of the subject diminish; the crucial determination is the measurement of the amount of oxygen in the mixed venous blood in the

right side of the heart, and no one has yet had the courage to show that this can be done by direct puncture with a needle and syringe. The main problem at present outstanding is whether the output is relatively constant or highly variable under ordinary conditions of life, and Prof. Yandell Henderson gives an illuminating discussion of the question in *Physiological Reviews*.² The argument that the output of the heart varies considerably has generally been somewhat as follows. In violent exercise the consumption of oxygen may increase to ten times the resting level; the pulse-rate rarely increases more than twice. Hence, during exercise either much more of the oxygen in the arterial blood must be consumed before it returns to the veins, or the heart at each beat must put out a good deal more than the resting volume of blood. It has been assumed that about one-third of the oxygen is used up in the tissues during rest, and if this proportion were doubled during exercise we could account only for a six-fold, as against a ten- or twelve-fold, increase in oxygen consumption during violent exercise, unless we allow that the heart's output at each beat is also about doubled. Henderson points out that recent knowledge is on the whole against this view, and urges that the "stroke volume" in a normal man is, within 20 or 30 per cent., a uniform quantity during all the activities of life. The mistake appears to have been that the difference in oxygen content between arterial and venous blood during rest has been exaggerated; the consumption is less than one-third and hence the resting circulation-rate is higher than has been supposed, and there is a large margin of oxygen consumption to be drawn on. An increase of two to three times in the pulse-rate and three or four times in the proportion of oxygen used will give the tenfold augmentation in the respiratory metabolism which is required during violent exertion. Thus in the beautiful experiments of Douglas and Haldane,³ Douglas at rest consumed 233 c.cm. oxygen per minute, and while doing violent work on the ergometer 1974 c.cm., an increase of 8.5 times; his pulse-rate rose from 53 to 137 (2.6 times), the percentage utilisation of his arterial oxygen from 19 to 64 (3.4 times), the minute blood flow from 7.5 to 18.7 litres (2.5 times), while the output of the heart at each beat remained constant at 135-136 c.cm. The important practical conclusion emerges from this that the circulation-rate is pretty nearly proportional to the pulse-rate in the changes due to rest and exercise. It remains to discover how far this holds in disease; whether, for example, the increased pulse-rate in fever means an increase in circulation-rate.

MEDICAL WOMEN'S FEDERATION: FIRST PUBLIC DINNER.

THE annual meeting of the Medical Women's Federation concluded this year with a highly successful dinner, to which a number of important guests were invited. Members of the Federation from all parts of England and Scotland sat down with their friends to the number of about 220. Lady Barrett, who presided with great geniality, stated that the membership of the Federation now amounted to about 800 and that it was affiliated to an International Federation, on which medical women of 19 countries were represented. The Earl of Onslow, who proposed "The Medical Profession," alluded to the opportunities for service now open to women, particularly in the sphere of the early treatment and prevention of mental disease. Sir William Hale-White, in response, spoke feelingly of the rewards of faithful medical work which were not generally of a material kind. Sir Sydney Russell-Wells, M.P., proposed "The Federation," reminding his hearers of the pioneer position of London University in the education of women, and of his experience that to be successful was to make the best use of disabilities; anyone could utilise opportunities. He spoke of the likelihood of the struggle for existence shortly becoming acute among medical women. Miss Ivens, in respond-

³ *Journal of Physiology*, 1922, lvi., 83.

ing, set out the main purpose of the Federation as to raise the standard of work among medical women and to promote active friendship among them, especially for the support of those in isolated places. Dr. Jane Walker proposed "The Guests" in anecdotal vein. Mrs. Wintringham, M.P., and Sir George Berry, M.P., responded. Mr. H. J. Waring proposed "The Chairman," suggesting to the Federation the appointment of an advisory body to weed out unsuitable entrants at the outset of their career. Lady Barrett, in responding, laughingly disclaimed on behalf of medical women the sagacity to foresee the successful practitioner in the girl leaving school. She and other women speakers refused to be pessimistic in regard to the outlook for the woman practitioner or her ability to earn her own living.

GONORRHOEA, EPIDIDYMITIS, AND STERILITY.

THE treatment of gonorrhoea and its complications in the educated man may be one of the most subtle problems that can confront a practitioner, and happy is one who can point to a series of cases where no permanent damage, physical or psychological, has been sustained. The widely disseminated knowledge of the aetiology and possible end-results of gonorrhoea, though it may be, and probably is, to the interests of the community as a whole, may complicate the position of the individual sufferer without bringing him much compensatory advantage. For though much is known in a general way, it is mostly impossible in the early stages even for an expert to inform a patient exactly where he is likely to stand as regards the two great horrors which may fill his mind with apprehension—infertility and sterility. Of these it is easier to prophesy hopefully as regards the former. The practitioner may nowadays with a fair degree of safety assure the patient that under careful treatment he will eventually be non-infective. The second remains a more doubtful proposition and depends largely on the success with which complications are avoided. The danger of sterility following an attack of gonorrhoea is, perhaps happily, less well known among patients, who do not realise that gonorrhoeal epididymitis is the commonest of all sources of sterility in the male. The figures published¹ by Benzler in 1898 are instructive. This observer followed the record of German soldiers with a previous history of gonorrhoea who had been married for three years or over, special attention being directed to a history of epididymitis. Of those who had escaped epididymitis, 10.5 per cent. were childless, of those who had had unilateral epididymitis 23.4 per cent. were childless, of those who had had bilateral epididymitis 41.7 per cent. were childless. It is clear that a great number of childless marriages must be due to a previous attack of gonorrhoea in the husband, and particularly to an attack complicated by epididymitis.

On page 1020 of our present issue Mr. Kenneth Walker sets out the main points of importance in treatment if inflammation of the epididymis, or at least such extensive fibrosis of its minute channels as may lead to sterility, is to be avoided. Physical problems, however, are less difficult to tackle than the psychology of the patient at the time of onset of the disease, at the time of the complicating factor of epididymitis, and at any future time when he may desire to marry. It is at these crucial moments, when the patient is suffering from the misery of self-reproach, that the practitioner may be called upon for information or reassurance, neither of which he is in a position to give without reserve. Here a word of warning may be in place. Many patients do not realise that the rigorous so-called "marriage tests" insisted on by careful surgeons are tests for infectivity only. It is unwise, however, to leave it at that and to allow them to marry, especially if they have had bilateral or even unilateral epididymitis, without a hint that they are less likely to be fertile than the normal man. The results of well-meant reticence on this point may be unhappiness or even recrimination

if the wife is subsequently examined and the probable cause of sterile marriage is traced to the unconscious husband. On the other hand, the practitioner who knows the temperament of his patient may fear to produce morbid questionings which may wreck two lives without due cause. In hospital practice it may be impracticable to do more than answer definite inquiries, but in private practice the suggestion of a fertility test would give opportunity for a discussion of the situation, even should no final verdict be reached. The best time to bring up the subject will hardly be the last of the three stages of anxiety to which allusion has been made. Rather let the first stage be chosen when, in the presence of personal physical discomfort and the possibility of infectivity, the menace of ultimate sterility seems, as indeed it is, remote. A warning uttered then could hardly further depress the spirit of one afflicted, and might help to ensure that rest in the early stages which Mr. Walker, in common with other authorities, regards as one of the most important factors in the prevention of complications which may lead to sterility.

EXPERIMENTAL CHOLECYSTITIS.

NEARLY 100 years separate us from the time when Louis first demonstrated the association of typhoid fever with lesions in the gall-bladder, but it was only in the "eighties" of the last century that experimental work on animals began to show us the true importance of such associations. These and subsequent researches are admirably summarised in a long essay¹ by M. G. Peterman, of the Washington University School of Medicine. In the same paper he gives an account of his own work, which confirms previous experiments and throws into strong relief certain important aspects of the problem of gall-bladder infections. His experiments may be briefly summarised as follows:—

1. Injections of cultures of *Staphylococcus albus* into the portal circulation of rabbits led to the appearance of the organisms both in the heart-blood and in the bile within three minutes of the injection.
2. The same result followed injection of the organisms into the veins of the ear; but if the cystic duct and neighbouring vessels were tied the results were negative. If, however, the cystic ligature was performed ten days before the injection the results were positive.
3. In another series of animals virulent organisms were injected into the ear veins. Seven or more days later four of the seven animals (rabbits) were found to have the organisms present in the bile and the remainder had an acute cholecystitis, although in none of them did the heart-blood now yield organisms.
4. A series of seven dogs were injected with cultures of *Staphylococcus aureus* into the portal vein, three of them were given a second injection, this time of *Streptococcus hemolyticus*, two to six days later. In all these animals the autopsy revealed cholecystitis affecting the wall of the gall-bladder and leaving the mucosa almost intact.
5. In the above animals an acute hepatitis was demonstrable in addition to the cholecystitis, and in four of them there was an interstitial pancreatitis as well.
6. In a series of rabbits a hemolytic streptococcus was recovered from the wall of the gall-bladder a few hours after injection of the organisms into the portal vein, and the same result followed injection of the organisms into the appendicular vein. In all such cases the liver and pancreas were also affected.
7. In one rabbit in which the organisms were injected into the walls of the appendix similar results were found.

Discussing these results Peterman lays stress on the lymphatic route of infection both in the production of cholecystitis and of its complications, hepatitis and pancreatitis, and argues that in cases of gall-bladder infections secondary to lesions in the bowel and portal system the organisms travel first to the liver and produce a hepatitis to which the cholecystitis is secondary. If this be the case it seems probable that the path from the liver to gall-bladder is via the lymphatics. He also calls attention to the relatively small degree of damage to the mucosa, as compared

¹ Arch. f. Derm. u. Syph., xiv.

¹ M. G. Peterman: Surgery, Gynecology, and Obstetrics, 1923, p. 522.

with the other layers of the wall of the gall-bladder in cases where that organ has been removed for inflammatory disease in human subjects, and finds in this confirmation of his view that such cases are examples of infection via the lymphatics from the liver. We notice that in this essay the author attaches considerable importance to the work of Rosenow who claims² to be able to produce specific lesions in rabbits—appendicitis, cholecystitis, gastric ulcer—by injection of streptococci recovered from abscessed teeth, or similar lesions in human subjects with such diseases. It is perhaps significant that this dramatic work, which was published in 1915, has as yet received no sufficient confirmation, and it is but fair to point out that without some such confirmation of the origin of such infections we remain very much in the dark as to the true nature of the pathology of cholecystitis and its complications.

PITUITARY SECRETION.

IN a contribution to the current number of the *Journal of Physiology*, Prof. W. E. Dixon deals with the conditions which cause secretion of the pituitary gland to meet the needs of the animal economy. Anæsthetised dogs were used; tracheotomy was performed, the blood pressure recorded, and all injections were made into the right femoral vein. The cerebro-spinal fluid was collected from the subcerebellar cisterna. The normal cerebro-spinal fluid showed every known chemical and physiological action of pituitrin, although the amount of this substance in the fluid varies greatly. A very large number of negative experiments was obtained; no form of stimulation of sensory nerves or of vagus and sympathetic in the neck caused any change in the secretion of the pituitary, and the inhalation of oxygen and carbon dioxide was likewise without effect. Certain drugs—e.g., alcohol, chloroform, urea, caffeine, histamine, adrenalin, several alkaloids, and glucose were injected or given by inhalation, all with negative results. Preparations of the posterior lobe of the pituitary injected into the general circulation caused pituitrin to appear immediately in the cerebro-spinal fluid. What purpose the pituitrin serves in the cerebro-spinal fluid is not clear, but any excess rapidly disappears. An excess in the blood is absorbed by the gland and some of it reaches the cerebro-spinal fluid; an excess in the cerebro-spinal fluid is excreted rapidly into the blood. The pituitary gland secretes into the cerebro-spinal fluid; pituitary extract injected into the circulation causes the gland to secrete, and when it is injected into the cerebro-spinal fluid it rapidly causes the ordinary systemic effects by passing into the general circulation. A balance is struck between the amount in the blood and the cerebro-spinal fluid. Many animal extracts were tried, and it was found that ovarian extract specifically excites the gland to secrete. The effect is immediate and lasts only two or three minutes. The active substance is not in the corpus luteum. Duodenal extract causes a secretion after one hour, but neither so much nor so constant as that caused by ovarian extract; the effect, however, is more prolonged. Some ingenious suggestions, hinging round the fact that the pituitary is a remnant of a gland once secreting into the alimentary canal, are made, so that it is perhaps not extraordinary that its secretion should be associated in some way with the functions of the alimentary canal. Pituitary extract increases tone in the small intestine, and diminishes tone in the large intestine.

THE LIBRARY OF THE COLLEGE OF PHYSICIANS OF PHILADELPHIA.

THE libraries of the New World continue to flourish, and the Library of the College of Physicians of Philadelphia ranks among the most prosperous. The total number of volumes in this great collection now numbers 136,489. During 1922, 6430 volumes were received, in addition to 10,418 pamphlets and 16,016

numbers of various periodicals. Donors in 1922 numbered 412, who between them have made 955 distinct presentations. The library is especially famous for its incunabula, of which it possesses 316 volumes. A score of works, some wellnigh priceless, have now been added, and these include the very early "Zophilogium" of Jacques Le Grand, printed by Rysch at Argentoratum (Strasbourg) in about the year 1470. This is the editio princeps of the once famous work, which Caxton translated into English under the title "A Book of Good Manners." Other very early books are the "Expositio Librorum Naturalium" of Aristotle, printed by Valdarfer of Ratisbon at Milan, 1476, and "Quæstiones de Tribus Principiis Rerum Naturalium" by Antonius Andreas, printed at about the same date by Canozius at Padua. The gem of these additions to an already unique collection is perhaps the "Contra Pestem" of Johannes Mercurius, printed at Rome by Johannes Besicken in 1493. The book is not mentioned by Hain, and is pronounced by Mr. Voynich to be the only known copy. It is not, however, the earliest treatise on the Plague, for Stainhöwel, of Ulm, had already in 1480 published "Von der Pestilenz" ("Regimen Pestilentiae"), although the latter fact does not seem to have been known to his translator, C. Ehrle, who described his manuscript in 1880. Other specifically medical works are the "De Plinii et Aliorum in Medicina Erroribus," of date 1492 (Ferrara), by Nicholaus Leonicensis, and Maimonides' "De Regimine Sanitatis ad Soldanum Babylonie," published at the Monastery of St. James de Ripoli in Florence in 1477. The works we have mentioned have been purchased by the "Fund for Rare Books" and the Funds of William F. Norris and Horace Magee. These agreeable resources are a feature of the Philadelphia Library for which English librarians can only envy their learned colleague, Mr. Charles Perry Fisher. To the Fund for Rare Books is also due the acquisition of a number of specially interesting sixteenth and seventeenth century works, including editions of David Abercromby, Abraham Aben Ezra, Henricus Cornelius Agrippa, Albertus Magnus, Valerius Cordus, Descartes, Raymund Lully, Simon Portius, to name only a few authors among many.

AN INDICTMENT OF THE PANEL SYSTEM.

THE panel system has been brought into the limelight by the criticism of the coroner for North-East London at a recent inquest. The conduct of the practitioner concerned will be a matter for further inquiry, but it appears to be necessary to remind the public that the conditions of medical practice so severely condemned by the coroner were in existence long before the panel system was established. In the *Daily News* there was recently published a very interesting article on "The Back-Street Practice," by Dr. F. G. Layton, in which a true picture is drawn of the state of things which formerly prevailed. "The club doctor was willing to work for a capitation fee so low that only numbers, extraordinary numbers, of capitation fees made it worth while. He had so many names on his list that he could deal with little, if any, of his work properly. In those days strangulated hernias were poulticed until they sloughed; appendicitis patients perforated and died . . ." Readers of THE LANCET may recall the investigations which resulted in the publication of the "Battle of the Clubs." If the poor man's doctor was overworked in those days, he is more heavily burdened to-day, when the poor industrial centres are in question, because the provision of medical benefit brings to his surgery insured persons who hitherto had recourse to the out-patient departments of our large hospitals, or who were treated under the Poor-law.

How is this state of things to be remedied? Some provision must be made for the great mass of illness which occurs in the overcrowded industrial neighbourhoods. The panel system has presented the best solution of the difficulty up to the present. The statement attributed to the coroner for North-East

² E. C. Rosenow: Collected Papers of Mayo Clinic, 1915, p. 276.

London, that "the panel system is a retrograde step, not too strongly described as a disastrous blunder and a miserable failure," is more than exaggerated. "Replace the present system," he says, "by one under which the doctor is paid for the actual work done, and the patient is free from restrictions both in choosing and in changing his medical attendant." But this proposal does not touch the root of the evil. The problem is one of adequate provision for the amount of work which requires to be done. Mere change in the method of payment cannot provide better attention and treatment when it is admitted that the number of practitioners in poor neighbourhoods is too small so that each has too many people to attend to. How can the frequent transfer of patient from practitioner to practitioner reduce the volume of work or make the work any easier? Payment on the basis of attendance is not likely to attract more doctors to these overcrowded areas. There are but 24 hours in the day, and it might be well if some of the critics of the panel system could experience the burden of the day's work of a busy panel practitioner. There is a limit to the time which can be devoted to consultations, not only because of the limits of physical endurance, but because the time devoted to visiting must not be curtailed.

The remedy which could be immediately applied would be a substantial increase in the number of practitioners in these areas. But well-qualified men will not be attracted to industrial areas if the remuneration is reduced.

STERILISATION OF TYPHOID CARRIERS BY REMOVAL OF THE GALL-BLADDER.

THE problem of the typhoid carrier in the general population is difficult enough in all conscience, and in asylums for the insane it is even more knotty for obvious reasons. The sane carrier can, in some cases, be persuaded to take certain elementary precautions which the insane cannot be expected to observe, and, as every asylum physician knows, it is often difficult to detect typhoid fever at an early stage in the insane. These, and kindred difficulties, are discussed in two papers published by Dr. A. Hottinger and Prof. C. Arnd (the latter since deceased, see THE LANCET, March 31st, p. 673) respectively in the *Schweizerische medizinische Wochenschrift* for April 26th. The asylum to which they refer has been unable for the past 20 years to stamp out an endemic of typhoid and paratyphoid fever, the staff as well as the patients falling ill from time to time. Various prophylactic precautions were taken, but new cases continued to crop up, doubtless because it was impossible effectively to isolate all the carriers. Accordingly, an attempt was made to sterilise 15 of these carriers by cholecystectomy, the whole of the gall-bladder being removed. In eight of ten persons who were typhoid carriers no typhoid bacilli could be found after the operation, but as far as the paratyphoid carriers were concerned, the operation proved to be futile. In two cases cholecystectomy in typhoid carriers was followed by the disappearance of typhoid bacilli from the stools, which then, however, were found to harbour paratyphoid bacilli. A somewhat disconcerting observation was made in the case of four typhoid carriers whose gall-bladders proved to be completely sterile; three of the five paratyphoid carriers were also robbed of perfectly sterile gall-bladders. At first sight it would seem that the operation in all these seven cases was ill-advised and useless. Perhaps it was. And perhaps the disappearance of typhoid bacilli from the stools in some of these cases immediately after the operation was a coincidence; the patients might have ceased to be carriers spontaneously and without the discomforts and dangers of an operation. There is, however, the possibility that the attendant incidents of the operation—ether anaesthesia and a restricted dietary for four to five days—may have played a part. Be this as it may, the prospects of sterilising paratyphoid carriers seem to be meagre on this showing, and even in the case of typhoid carriers cholecystectomy has

a very uncertain action. It has recently been pointed out by Dr. Murstad, of Bergen, that cholecystectomy is of personal advantage to the carrier of typhoid bacilli as well as to his potential victims, because the gall-bladders of carriers often harbour calculi as well as typhoid bacilli. But among the 15 patients treated by Dr. Hottinger and Prof. Arnd there were only eight in whose gall-bladders calculi were found.

THE YALE SCHOOL OF NURSING.

THE tenth anniversary on May 14th of the granting of a charter to the Rockefeller Foundation was the occasion of a statement by the secretary of the total sums disbursed during ten years. Public health has benefited to the extent of 18 million dollars; medical education to the extent of nearly 25 million. The most recent gift of the Foundation has been to endow a School of Nursing to be founded in the University of Yale. This Foundation is the outcome of the increasing recognition by leaders of public health work in America of the importance of the public health nurse. The school will not, however, be limited to training for this field, but will provide instruction in every branch of nursing. Unnecessary drudgery is to be no part of the student nurse's curriculum. The length of the course, the periods to be allotted to theory and practice, and the question of a degree in nursing still remain to be settled. The novelty of the scheme necessitates cautious development, but it may safely be assumed that the school will play an important part in the future of nursing. The first director of this school has been appointed. She is Miss Annie W. Goodrich, now assistant professor of nursing at Teachers' College, Columbia University, and for the last seven years director of nursing at the Henry Street Settlement.

DECAY IN STONE.

UNTIL Pasteur showed that decay was the result of bacterial infection it was generally supposed that foodstuffs, and indeed organic matter in general, underwent a natural and inevitable process of dissolution. In the same way the view has too long been held that decay in building stones is a natural process, and that the only way of preserving historic buildings and ancient monuments is to replace with new material as occasion arises the parts which have disappeared. It has now been decided to set up under the Department of Scientific and Industrial Research a special committee of the Building Research Board to report on the best methods by which such decay may be prevented or arrested. It is presumed that the investigation is likely to be complex, and in order to approach it from different angles with the help of wide scientific knowledge three Fellows of the Royal Society have been appointed members of the committee which will be presided over by Sir Aston Webb. Communications may be addressed to the Secretary of the Department at 16, Old Queen-street, London, S.W. 1.

THE next session of the General Medical Council will begin on Tuesday, May 29th, at 2 P.M., when a report will be made by Sir Donald MacAlister on the work of the Council since the November session, and penal and other matters will be considered.

THE twelfth Biennial Huxley Lecture on Recent Advances in Science and their bearing on Medicine and Surgery will be given at the Charing Cross Hospital Medical School by Sir Arthur Keith, at 3 P.M., on Wednesday, June 27th, when the chair will be taken by Dr. William Hunter. Admission to the lecture free without ticket.

MEDICAL OFFICERS OF SCHOOLS ASSOCIATION.—A meeting will be held at 11, Chandos-street, Cavendish-square, London, W. 1, on Tuesday, May 29th, at 5 P.M., when Dr. Alice E. Sanderson Clow will read a paper on the Effect of Physical Exercise on Menstruation.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

XX.

TREATMENT OF GONOCOCCAL EPIDIDYMITIS AND ITS BEARING ON STERILITY.

SINCE it is mainly on account of the complications to which it may give rise that gonorrhœa is such a serious disease its successful treatment lies in the avoidance of complications and especially of such complications as prostatitis and its sequelæ. Unfortunately, it is not in the power of the medical man to safeguard his patient from all the dangers to which his attack of gonorrhœa has exposed him. The factors that determine the spread of infection from the anterior to the posterior urethra are no more within his control than are those that determine the spread of a pharyngeal infection to the larynx within the control of a laryngologist. Nevertheless, by judicious treatment he can, at least, minimise the chances of epididymitis with its attendant risks of sterility.

Preventive Treatment.

The most important of all the measures directed to this end in a case of acute gonorrhœa is undoubtedly rest. Were it possible to do so I would confine to bed every patient of mine who was suffering from acute gonorrhœa, and would keep him there until the acute stage of the disease were over. By such means alone the number of those who subsequently developed epididymitis would certainly be halved. If complete rest is impossible owing to the circumstances of the patient his doctor must, at any rate, insist on the avoidance of all unnecessary exertion for the first three weeks or so of the attack, and must strictly limit the amount of exercise allowed during the whole of the time that the patient is undergoing treatment. Many an attack of epididymitis occurring at a later stage in the disease has followed an injudicious bicycle ride embarked on when the patient has been under the impression that he was cured and able to do what he liked.

The second point of paramount importance in the prevention of epididymitis is the avoidance of all trauma to the testis. In my opinion gonococci are in a large percentage of cases present in the tissues of the testicle even although signs of active inflammation are absent. It wants but the additional factor of bruising and lowering of tissue resistance to precipitate an acute inflammation, and since few structures in the body are more exposed to continual trauma than those in the scrotum every patient suffering from acute gonorrhœa should be provided with a suspensory bandage designed to keep the testicles well braced up and, as far as possible, out of harm's way. The adoption of such a precaution should be immediate and not undertaken merely when the patient complains of aching in the testicle, and it should be regarded not as a curative but as a preventive measure.

The third factor of importance is the avoidance of irritation of the posterior urethra. Whether the infection of the epididymis be due to the spread of organisms down the lumen of the vas, as is generally believed, or whether it be due to their spread along the surrounding lymphatics, as I have attempted to prove,¹ it is, at any rate, certain that irritation of the posterior urethra is generally the exciting cause of the attack. The mucous membrane of the posterior urethra is one of the most sensitive and easily damaged lining membranes in the body, and must be treated with immense respect, especially when it is in a state of inflammation. Hence the necessity for excessive caution in the technique with which irrigation is carried out.

Precautions in Irrigation.

High irrigators and strong lotions were together productive of thousands of cases of epididymitis during the war, and even at the present time certain clinics produce an unnecessarily large crop of epididymitis cases as a result of unskilful irrigation. The question as to whether posterior irrigation should be carried out at all in the earlier stages of gonorrhœa is one on which experts differ. A widespread fear exists in the minds of the public and the profession alike that posterior irrigation may carry infection back from an infected to an uninfected area, and thus help the spread of the disease. This danger is, however, theoretical and more apparent than real. The answer as to whether it is wise to proscribe posterior irrigation from the start is one that can only be supplied by a careful comparison of clinical results. Are complications commoner when posterior irrigation is used as a routine, even in cases that clinically give no indication of an infection of the posterior urethra? Personally, as the result of observations at my clinic at St. Bartholomew's Hospital and elsewhere, I believe they are, and for this reason I recommend that when treating an acute or subacute urethritis, which clinically at any rate appears to be confined to the anterior urethra, anterior irrigation alone should be carried out.

Before leaving this subject it is advisable to utter a word of warning against the employment of two methods of treatment—the syringe and the medicated bougie. Both are highly productive of epididymitis and have the additional quality of being inefficient. It is almost impossible for a patient when injecting himself with a syringe to regulate the pressure at which the fluid is introduced, for it is very seldom that the piston runs with uniform smoothness in the barrel. Of medicated bougies little need be said, except that most of us have at one time employed them and have quickly abandoned them. Additional exciting causes of epididymitis are the passage of instruments during the acute stage of the disease, and over-vigorous or premature massage of the prostate, both of which may be grouped under the aforementioned heading of irritation of the posterior urethra.

The Relief of Pain.

The treatment of epididymitis, once it has occurred, consists of measures directed to the relief of pain and to the hastening of resolution. The pain is sometimes intense and may call for somewhat drastic methods of treatment. It is due to intense congestion and oedema of the testicle and to the fact that the tunica albuginea only allows a certain amount of expansion. For such cases the rational treatment is puncture of the congested epididymis. This may be done by means of a hypodermic needle and syringe, the syringe being used to draw off as much serum and blood as possible. More drastic proceedings have been advocated, such as puncture with a fine tenotome or even open incision. These methods would certainly appear to involve the risk of inflicting permanent damage on the epididymal canal, and thus be productive of future sterility. Fortunately they are rarely if ever required. If necessary the puncture may be combined with the use of a morphia suppository.

Various applications to the scrotum have been recommended from time to time—guaiacol ointment, belladonna, ichthyol, and various preparations of iodine. I am convinced that none of these is so effective as the application of heat. Heat may be applied as fomentations, hot baths, steaming, or best of all by means of diathermy. Without doubt the most satisfactory results at my own clinic have been obtained through the use of diathermy, but when this is not available the simpler remedies will be found not only to give relief but also to hasten resolution. During the attack of epididymitis all intra-urethral treatment must be postponed. When the attack has subsided it is as well to warn the patient that it will take a month or two for the swelling of

¹ THE LANCET, 1913, i., 435.

the epididymis to disappear entirely and that for a long time a small nodule will be found in the lower pole. When resolution is very tardy I have sometimes found the use of a large dose of vaccine and the provocation of a strong reaction to hasten matters.

KENNETH M. WALKER, F.R.C.S. Eng.,
Lecturer in Venereal Diseases, St. Bartholomew's
Hospital; Surgeon in Charge of Genito-urinary
Departments at the Royal Northern and
Miller General Hospitals.

Special Articles.

DENTAL BOARD OF THE UNITED KINGDOM.

ADDRESS FROM THE CHAIR.

THE fourth session of the Dental Board of the United Kingdom was held on May 9th, 10th, and 11th at 44, Hallam-street, London, W., the Rt. Hon. F. D. Acland being in the chair. In his address, Mr. Acland referred to the fact that upon this occasion the Board met for the first time in its own Board Room, and spoke of the harmonious and useful work which he hoped would there be carried out. He expressed the gratitude of the Board to the General Medical Council for help given by lending their offices, and in every other possible way, and to Sir Almeric Fitzroy for conspicuous services rendered to the dental profession, in his capacity as clerk to the Privy Council, in the formation of the committee upon whose reports the Dentists Act of 1921 was founded, and in active membership of that committee. The Finance Committee, continued Mr. Acland, would submit to the Board an estimate of receipts and expenditure for the year ending Dec. 31st next. The estimated income of the Board for the year, about £45,000, would be sufficient to discharge its ordinary expenses, to pay the balance of about £13,000 not provided for in the previous year for building and equipment, and to leave about £20,000 available for research and education, of which approximately £3,000 had already been appropriated for grants and loans. The Finance Committee had estimated that £1500 would be required for legal expenses; the Board was now practically concluding one chapter of work entailing legal expense—that of registration—but another, connected with discipline, was now opening before it. Mr. Acland emphasised the fact that, to the exact extent to which it was necessary to take proceedings for the enforcement of a proper standard of conduct in the profession, money was subtracted from the funds available for the advancement of the profession through education and research.

Assistance of British Students.

Progress had been made, he continued, towards assistance of persons who were debarred from registration as dentists by being under the age of 23 at the date of the passing of the Dentists Act. At the request of the President of the General Medical Council some of the Licensing Bodies had agreed to accept them as students without requiring the usual standard of general education preceding their entrance upon professional study. The Board would be asked to approve the setting aside of a sum to assist with regard to fees, and in some cases maintenance, such of these persons as satisfy examiners appointed by the Board of their competence in mechanical dentistry, and show that they are unable to qualify without this assistance.

As, however, it did not yet appear very likely that suitable persons from this class would come forward up to the numbers which the Board could afford to assist, letters had been written to head masters and mistresses of a large number of secondary schools, informing them that the Board hoped to be in a position to assist students suitable for, but unable to

take, the dental curriculum owing to want of means, and asking them to recommend names. Twenty recommendations had already been received. It would be a proud boast if in course of time the Board could say that no suitable student was debarred from entry to the profession by lack of means.

Lectures and Post-Registration Study.

Admirable courses of four lectures had been delivered, under arrangements made by the Board, in London, Edinburgh, and Manchester, on diseases of the periodontal tissues due to infection in their relation to toxæmia; these lectures were, he believed, very keenly appreciated by large audiences at every centre. He was sure that the Board would wish to receive proposals for future similar courses, and would desire to consider the development of post-registration study.

Grants to Ex-Service Students.

Grants had been made to ex-Service students, who would otherwise have been left stranded towards the end of their professional courses by the cessation of grants from the Government; these grants might involve a total payment of about £3500 out of this year's revenue. In not a few cases the persons assisted had already qualified, and several of them had written expressing their gratitude for timely assistance. The Education Grants Committee had begun on a small scale to make loans to students not in receipt of Government grants who found themselves unable for unforeseen reasons to complete their courses. The Committee would present to the Board an abstract showing the accommodation and facilities for training possessed by the dental schools, with an outline of their future needs, showing in general that extension and improvement of premises are both desirable and desired by the school authorities, and that, while space for extensions is available, funds are not. The Board would, in Mr. Acland's opinion, not be able at any very early date actively to assist development, but he hoped that before the end of the year they might be in a position to make offers of future help.

Research.

Progress would be reported as regards research, both on its medical and on its scientific side. The Board would be able to consider a definite scheme of research in which they were asked by the Medical Research Council to coöperate. The Department of Scientific and Industrial Research had welcomed the possibility of help as warmly as the Medical Research Council. The Board was represented on a provisional committee set up by the Department, whose task was to inquire how the problems which it was desired to examine could best be fitted into work already under investigation, and to make recommendations for carrying the work forward.

Discipline.

The Discipline Committee had given much consideration to problems arising in the interpretation of the Board's Warning Notice. Many inquiries had been received as to the circumstances under which it was to be allowable to insert a notice in a newspaper as to change of address or hours of attendance at a particular address, to use the words "dental surgery," and to use illuminated signs. Without committing the Board on the subject, the Committee had given provisional rulings on these points, which rulings, he suggested, should be considered by the Board during its session, and if approved should be published for general information. He was very much impressed by the evident desire of the vast majority of those newly admitted to the Register to maintain honestly and honourably a standard of conduct which would accord with the Board's wishes; and the Board, he thought, owed it to them to give as clear a ruling as possible upon points which might be genuinely in doubt.

Coöperative Societies and Dental Treatment.

Negotiations had been proceeding between associations and societies of dentists on the one hand and representatives of the industrial coöperative move-

ment on the other, with regard to the conditions under which coöperative societies should arrange for their members and members of their families to receive dental treatment. These negotiations arose out of the proceedings at the meeting of the Board on Nov. 21st, 1922, which were followed by a conference between the parties at the offices of the British Dental Association. Only unimportant details remained for settlement, and complete agreement had been reached on the main principles of a scheme of working. A panel would be formed of all dentists willing to accept a certain scale of fees mutually agreed upon, thus avoiding the advertising of a particular dentist which had hitherto frequently occurred; and the dentist would receive the agreed scale of fees from the society without deduction, which would avoid other undesirable aspects previously occurring in certain cases. If, as Mr. Acland hoped, the Board's scrutiny of the agreement when presented revealed no undesirable features, only its administration would remain to be watched, in which direction he anticipated no difficulty, being convinced that the coöperators' representatives, like the dental bodies, would do their utmost to see the agreement speedily and loyally carried out. The Board might, however, have more difficulty in securing the elimination of undesirable elements in the arrangements between dentists and bodies of persons outside the coöperative movement.

Practice by Unregistered Persons.

In conclusion, Mr. Acland dealt with the proceedings which the Board has already taken to secure that dentistry shall not be practised by unregistered persons, and that it shall be practised by dentists in conformity with the Warning Notice. The Board's solicitor had up to Easter taken action in 132 cases of persons continuing wrongfully to practise after Nov. 30th last. The majority of these were persons registered last year who had not paid the retention fee for this year, or persons whose applications were found to be in order last year but had paid the fee neither for last year nor this. Several had pleaded illness as an excuse, but, as the Board's solicitor had pointed out, a man well enough to practise was well enough to sign a cheque. A minority of cases—22 in all—were of persons who had either never applied to be registered, or who in their applications had not satisfied the Board's requirements. The work of clearing up these cases had been proceeding satisfactorily. It had seemed necessary to take actual legal proceedings in only four cases as yet, and in all of them the prosecution was successful. He was glad to be able to bear witness to the valuable assistance rendered in these cases by the police.

Breaches of Warning Notice.

With regard to alleged breaches of the Board's Warning Notice, which it was necessary to remind certain writers in the dental press were not breaches of law and therefore could not be dealt with through the police, a vigorous and systematic taking up of cases properly reported had served in very many cases to secure immediate promises of amendment, which had been without doubt generally carried out. A residue of cases in which by direction of the Discipline Committee persons would be charged with infamous or disgraceful conduct in a professional respect, remained for the Board's consideration. The experience so far gained, Mr. Acland stated, had shown that the Board was not unwise in requiring a complainant in certain cases to set out the facts of the case in a statutory declaration. The Board did not necessarily want the complainant to conduct the case before it, but he must show that there were genuine grounds for inquiry, this being a necessary guarantee that the complaint was bona fide and not vexatious. The Board must ask for some slight element of coöperation from the profession, and he could not imagine that any one affording it would, as had been suggested, be placed in an invidious position to the prejudice of his social and professional status.

DISCIPLINARY AND OTHER MATTERS.

At the conclusion of the Chairman's address the Registrar reported the restoration to the Dental Register of the names of Emile H. Chapman, Richard K. Devonshire, Wm. E. Ganney, and Wm. H. Loosely.

Dentists Carrying on Another Business.

Mr. E. L. Sheridan asked whether it was permissible for a dentist to carry on another business (e.g., that of bookmaker or dancing master) at the same time as he is practising dentistry. The Chairman gave the following ruling: "It is permissible for a dentist to carry on any other occupation which is itself lawful at the same time as he is practising dentistry, and the Board have no power to interfere."

Registration.

The Chairman of Business, in the absence of Mr. Stirling, in his behalf called attention to the concluding words of the first schedule of the Dentists Act, 1921: "Provided that the powers of the Board in connexion with admission to, erasure from, and restoration to the Register shall be exercised by the Board itself and shall not be delegated to any committee." He pointed out that in accordance with these words all the business of the Registration Committee must be reported to and confirmed by the full Board before it can have any legal effect.

The Chairman gave the following ruling: "The proviso to Section 9 of the first schedule to the Dentists Act, 1921, relates only to the powers of the Board and the method of their exercise. The proviso does not apply to the purely ministerial act of the Registrar in admitting to the Register. The Registrar and other officials of the Board act under the direction of the Board, and when an applicant for registration has complied with all the requirements of the Act he must be registered, and the Board have no power to refuse him. It is true that in certain cases of doubt or when objection has been lodged the regulations of the Board provide that the Registrar shall refer the matter to the Registration Committee, who ascertain the facts. If the Committee find on the facts that the applicant has complied with the requirements of the Act he is registered. If they find otherwise the case is referred to the Board. The refusal to register is an exercise of one of the powers given to the Board. This power has never been delegated; it is always exercised by the Board itself whenever the refusal has been questioned by an applicant."

Penal Cases.

Ten cases were considered by the Board. Of these, two were forwarded for the consideration of the General Medical Council. A third case, in which the offence was covering, had been twice adjourned from previous sessions of the Board; the Board did not see fit to recommend erasure from the Dentists Register. In the remaining seven cases the offences consisted of various forms of advertising or canvassing; of these, two cases were dismissed with the customary warning as to future conduct, and the remainder were postponed till the November session of the Board, the dental practitioners concerned being required to supply satisfactory evidence of their conduct in the interval. In several of these seven cases the Chairman emphasised the fact that the offence was among the first of its kind to be brought before the Board, and a certain leniency was exercised in view of possible misunderstandings. The majority of practitioners concerned had discontinued the practices complained of, and readily undertook that there should be no repetition of them. Two cases were of advertising in newspapers, and in two other cases the practitioner had "sought to procure patients by sending out circulars to patients . . . suggesting that they should canvass" on his behalf. In one case an advertisement which had appeared in a theatre programme for 20 years was overlooked by a practitioner admitted to the Register under the Dentists Act, 1921. In another case advertisements had been hung in an hotel and in a restaurant, and a dentifrice had been supplied to chemists with transparencies and wrappers bearing

the name and address of the registered dentist in question; the latter had, however, taken steps to replace the chemists' stock and to secure the removal of the advertisements.

A Dentist's Street Signs.

The remaining case was that of a practitioner summoned to appear before the Council on a charge of advertising by exhibiting on numerous parts of his premises his name and qualification, together with other words (e.g., "The old-established dentist," "advice free," "moderate charges," &c.), "such being in size and quantity greatly in excess of anything required for legitimate professional purposes."

This practitioner, who had first been registered as in practice on July 22nd, 1878, had appeared before the General Medical Council in 1914 and 1915, and claimed to have received the sanction of that body for the signs complained of, as represented in photographs. He also claimed that his signs (some of which were in letters 18 inches high) were necessary in the busy thoroughfare in which he practised, and asked for a definite ruling as to what size of lettering would be sanctioned by the Board. The Chairman explained that the Board could not indicate exact sizes or brightness of lettering, or the number of times a practitioner might display his name, as that would entail visiting every place in the country where the profession of dentistry was carried on. Different rulings were necessary in different places; what the Board wished for, and intended to enforce, was that amount of indication which might reasonably be regarded as sufficient to guide persons desiring treatment to the location of, and entrance to, the premises where that treatment could be obtained. Nothing would be tolerated which might be construed as advertisement.

The practitioner indicated on a photograph the extent to which he felt prepared to modify his business signs; the Board could not accept the degree of modification proposed, and the case was adjourned till the November session, the Chairman advising the practitioner to reconsider his position and to be guided by the Board's advice.

PSYCHO-PATHOLOGY FOR THE GENERAL PRACTITIONER.

A SUGGESTED SCHEDULE OF TRAINING.

In his Memorandum to the Minister of Health on Recent Advances in Medical Education (see THE LANCET, May 5th, p. 809), Sir George Newman points out that the practitioner's approach to mental disorder should be through a twofold training, in psychology and psycho-pathology. The former should belong to physiology in its wide sense, the latter falls within the clinical years. Between the two, or as part of either, may well come a brief course of a few lessons in medical psychology, with particular reference to psycho-neuroses, with instruction as to the examination of patients, the practice of suggestion and persuasion, psychological analysis, and mental testing. To these courses would be added clinical work, first in a mental hospital and then in the out-patient clinic for nervous and mental disorders at the general hospital.

The curriculum in mental diseases which he suggests is as follows:—

1. A short course of lectures (5-10) in normal psychology, preferably as part of the course in physiology (reflexes, habit, instinct, emotion, intelligence, the conscious and the unconscious mind, Binet tests, investigational methods, &c.).
2. Half a dozen explanatory discourses in abnormal psychology to be taken concurrently with clinical work in mental disease.
3. Ten or 12 systematic lectures on mental disease, concurrently with clinical work, and clinical demonstrations at a mental hospital of in-patients, pronounced cases (recent or chronic), and the usual types of insanity.
4. A series of demonstrations in the out-patient clinic for nervous and mental disorders at the general hospital.

What the student needs is instruction in the ætiology, symptoms, diagnosis, treatment and prognosis of the morbid mental states most commonly met in general practice. And Sir George Newman adds a statement which comprises suggestions as to the principal sphere of psycho-pathology for the medical practitioner. Its purpose is to set out in schedule form the main points and their mutual relationship.

"*Unsoundness of Mind*" as a comprehensive term, including mental deficiency and mental disorders: conception and ætiology of—including the biological aspect; physical and toxic factors and the relation of endocrine disturbance; and such mental factors as mental trauma, prolonged mental stress, the repression and operation of "complexes," and subconscious states. The relation of psychological to general medicine. The preventive importance of the foregoing considerations.

Mental Deficiency.—Degrees of, as defined by Statute. "Stigmata" of degeneration. Sociological importance of "moral imbecility." Distinction between mental deficiency and backwardness. Recognition of the more important clinical forms. Principal lines of treatment, supervision, and training.

Mental Disorders—including the psycho-neuroses and the more important of the psychoses. The symptomatology includes insomnia, confusion, delirium, hypochondriasis, depression, agitation, exaltation and excitement, illusions, hallucinations and delusions, sexual perversions, &c.

(a) *Psycho-neuroses*.—Hysteria, anxiety neurosis (including possible relation to exophthalmic goitre). Neurasthenia. Obsessional states: their symptoms, diagnosis, prognosis, and treatment. Differential diagnosis between so-called functional and organic conditions.

(b) *Psychoses*.—General paralysis: its ætiology, early symptoms, course, prognosis, and treatment. Mental disorders in connexion with epilepsy. Dementia præcox, paraphrenia, paranoia, and manic-depressive psychosis—outline of these conceptions and group forms and of their respective phases, with symptoms and treatment of the earlier stages. Confusional psychosis (states of confusion and delirium): toxæmia, exhaustion, and other ætiological factors; symptoms; diagnosis; prognosis and treatment; multiple foci of infection. Alcoholic psychoses: Delirium tremens, chronic alcoholic hallucinosis, alcoholic paranoia, and polyneuritic psychosis. Alcoholic excess and other psychoses. Drug-habit psychoses: Morphinism, cocaineism, &c. Arterio-sclerotic psychosis, especially its earlier symptoms and their treatment, and senile dementia. Traumatic psychoses and others associated with organic brain disease. Endocrinal psychoses: Myxœdema; exophthalmic goitre, acromegaly, &c.

(c) *Epical and other "Critical" Influences*.—Puberty, adolescence, climacterium, and senescence; gestation, puerperium and lactation. The relative likelihood at each of these periods of the onset of one or other of the psychoses. The milder mental disturbances, not amounting to a psychosis, liable to be associated with each period, and the treatment of these disturbances.

The Services.

ROYAL ARMY MEDICAL CORPS.

THE undermentioned retire on ret. pay: Lt.-Col. G. B. Riddick; and Maj. G. R. Painton, on account of ill-health contracted on active service, and is granted the rank of Lt.-Col. Surg. Capt. G. O. Chambers, from Life Guards, to be Maj.

Maj. W. E. Marshall is restd. to the estab.

Capt. and Bt. Maj. N. V. Lothian retires, receiving a gratuity, and is granted the rank of Maj.

General List: Capt. E. E. Lightwood (late of R.A.M.C.) to be Capt. Capt. J. C. Newman, having attained the age limit, is retired and retains the rank of Capt.

Capt. A. G. M. Middleton resigns his commn. and retains the rank of Capt.

Lt. H. Mather to be Capt.

W. J. Roche to be Lt.

General Hospitals: The undermentioned, having attained the age limit, are retired and retain their rank except where otherwise stated: Lt.-Cols. H. R. Vachell, T. Wallace, and E. Le C. Lancaster; Majs. W. M. Stevens (granted the rank of Lt.-Col.), P. R. Griffiths (granted the rank of Lt.-Col.), C. Lewis, D. R. Paterson, B. W. Broad, A. Howell, C. A. Griffiths, W. F. Brook, A. T. Waterhouse, J. S. Bury, and Sir W. Milligan; Capts. A. Sellars (Bt. Maj.), R. W. MacKenna, R. T. Williamson, C. H. Melland, W. J. S. Bythell, R. W. Marsden, A. Donald, H. Lund, C. Roberts, A. E. Barclay, R. C. Elsworth (granted the rank of Maj.), H. A. Scholberg, W. J. Greer (granted the rank of Maj.), T. M. Thomas (granted the rank of Maj.), W. Nicholson, E. Reid

(granted the rank of Maj.), F. G. Thomas, O. W. Morgan, C. B. Gratte, R. J. Coulter.

Cpts. T. B. Mouat and E. M. Woodman relinquish their comms. and retain the rank of Capt.

Capt. R. Ollerenshaw relinquishes his commn. and is granted the rank of Maj.

Supernumerary for service with O.T.C. : Capt. C. H. Budd to be Local Maj. whilst comdg. a Section of the Field Amb., Cambridge University Contingent, O.T.C.

TERRITORIAL ARMY RESERVE.

Capt. E. J. Y. Brash relinquishes his commn. and is granted the rank of Maj.

Capt. W. Seymour, from 1st Northern Gen. Hosp., to be Capt.

Capt. S. G. Webb, from 1st Southern Gen. Hosp., to be Maj.

ROYAL AIR FORCE.

The undermentioned are granted temporary commissions in the ranks stated : Flight Lt. T. Sheehan ; Flying Officer K. R. Smith.

The undermentioned Flying Officers to be Flight Lieutenants : W. E. Barnes and C. A. Lindup.

Squadron Leader A. G. Higgins relinquishes his temporary commission on ceasing to be employed.

INDIAN MEDICAL SERVICE.

Majors R. Kelsall, J. McC. A. Macmillan, C. A. Gill, R. F. Steel, G. W. Maconachie, E. W. C. Bradfield, A. W. M. Harvey, C. I. Brierley, J. B. D. Hunter, and E. T. Harris to be Lt.-Cols.

Ram Mansoor, Santosh Kumar Ganguli to be temp. Lt.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following table gives the principal statistics of a group of sanitary districts for 1922.

Name of district.	Estimated population (mid-year).	Birth-rate.	Death-rates per 1000 of population.				Death-rates per 1000 births.		
			All causes.	Tuberculosis.	Cancer.	Respiratory with influenza.	Infant mortality		Maternal mort. in childbirth.
							Legit.	Illegit.	
Stafford B. . .	29,260	16.9	11.2	1.2	1.0	3.0	67	167	0.0
Cambridge B. . .	58,900	15.3	11.4	0.8	1.5	2.5	68	97	3.3
Ramsgate B. . .	30,030	19.5	14.8	1.3	1.5	2.7	57	71	6.8
Finchley U.D. . .	46,830	16.6	10.5	0.6	1.4	1.8	43	173	2.6
Chingford U.D. . .	9,494	21.1	10.4	—	—	—	56	200	0.0
Barnstaple R.D. .	17,980	17.9	13.5	1.3	1.1	2.4	56	46	3.1
Plympton St. } Mary R.D. . }	21,080*	17.7	12.4	1.0	1.2	1.8	39	100	—
Thedwastre R.D. .	8,493	21.8	12.6	0.2	0.9	—	59	200	0.0
East Stow R.D. .	6,422	17.9	11.4	0.9	2.3	—	82	0	8.7

* For deaths. B., borough. U.D., urban district. R.D., rural district. Where a short line is given the figure is not available from the report.

Stafford.

Dr. J. T. MacNab reports that the very success of the infant welfare centre is hampering its work. More sessions are needed and a second health visitor. The "free milk" has been of the greatest value in promoting breast-feeding. The sanction of the Ministry is being asked for a grant towards work done for the centre by the orthopaedic clinic. A large proportion of the water-closets are of the waste-water type and give rise to trouble through stoppages. The housing difficulty continues to be a serious problem. Dr. MacNab advocates the building of simple houses in rows or terraces for the poorest families, to be kept under supervision; the private landlord will not accept tenants of this type; some of them are known to be bad tenants.

Cambridge.

Dr. Andrew J. Laird reports an unusual outbreak of scarlet fever at Addenbrooke's Hospital which appears to have been due to a healthy carrier in the person of a wardmaid, E. B., who was subject to sore throats, but had never had an attack of scarlet fever. Of 32 cases, in addition to sore throats, 18 occurred in E. B.'s ward. Visits by E. B. to a distant home and to another ward to see the child of a friend were followed by cases of scarlet fever. E. B. had tea with the wardmaid who succeeded her and her successor sickened with scarlet fever in a few days.

Otherwise the cases, which had continued from December, 1921, to May, 1922, ceased after E. B. left the service of the hospital. E. B. had chronic enlargement of the tonsils and a deflected nasal septum; her brother and sister had scarlet fever in 1910 but she escaped. Dr. Laird says that "the provision of more housing accommodation is still the great outstanding need." During the year 97 houses have been completed by the corporation and 38 by private enterprise. Dr. Laird advocates the building of a smaller and cheaper class of house and suggests mixing the three bedroom type with small terrace blocks of houses, containing two bedrooms, a living-room, and scullery and no bathroom. A nuisance has arisen from some of the college ditches. Sewage was not the cause, and the trouble was found by Dr. L. Cobbett to be due to the growth of algae on the surface of the dead leaves. In one ditch a beautiful purple coloration was found to be due to the growth of *Bacillus violaceus* on the leaves. The public dental officer, Mr. W. B. Grandison, reports on the progress of the maternity and child welfare dental scheme inaugurated in 1921. The expectant and nursing mothers have free treatment (with dentures, &c. at cost price) on condition that they enrol their pre-school children for dental inspection once a quarter. Under the scheme 139 mothers have been treated and 91 pre-school children enrolled. The condition of the mothers' teeth before and after treatment was as follows:—

Condition of Teeth of Nursing and Expectant Mothers.

—	Sound.	Saveable.	Unsaveable.	Missing.
Before treatment. .	987	95	1525	1489
After „	1053	29	185	2829

The treatment for the children was advice as to correct diet and oral cleanliness and the application of nitrate of silver to decayed saveable teeth to arrest decay until such time as the teeth can be filled.

Ramsgate.

The two special points stressed by Dr. W. J. Bannister are housing conditions and the pollution of shell-fish. Housing conditions are as they were in 1919, and houses unfit for human habitation and overcrowding cannot be dealt with. The Ministry have promised a special inquiry with regard to shell-fish from polluted sources. Out of three notified cases of typhoid fever, two were associated with the consumption of cockles from the mouth of the Stour. The council have a shell-fish station where cockles, &c., can be sterilised. No charge is made for shell-fish intended for consumption in the borough and a nominal charge for those exported to other districts. A suspected milkman was caught in the act of watering milk. He was charged by his employer with "damaging milk" and fined £5 or 21 days, and 6s. 9d. for the damage to the milk. Analysis showed the milk to have 12 per cent. added water and to be 14 per cent. deficient in fat. There are two council schools and seven "non-provided." The former are satisfactory, but most of the latter are old, of defective design, and as regard lighting, ventilation, and equipment, cannot be considered to comply with modern requirements.

"Surprise" cleanliness inspections have effected considerable improvement in verminous conditions. Out of 166 children needing treatment for tonsils and adenoids, only 18 received operative treatment, many of the cases yielded to regular breathing exercises following dental treatment. Dr. Bannister favours the appointment of an organiser of physical training and the formation of classes for corrective exercises for commencing deformity, round shoulders, and flat-foot.

Finchley.

Dr. Wilson Jameson reports that the negotiations for a joint isolation hospital with Hornsey and Wood Green were successfully completed in 1922. Refuse continues to be dumped and burnt at the sewage farm, and negotiations are in progress with Friern Barnet for a joint scheme for the disposal of refuse. 188 houses were erected during the year, 102 of which were part of a municipal scheme. The opening of the new cleansing station has brought about a definite improvement in the cleanliness of the school-children. The school dentist, Mr. G. H. W. Randell, reports that the parents are the chief obstacle to conservative work on

the temporary teeth of the school-children. Swimming is a feature at Finchley; the head teachers take a great interest in it and there were over 20,000 attendances during school hours at the public baths.

Chingford.

Dr. E. J. F. Hardenberg reports that the objectionable practice of dumping refuse at various tips has now been discontinued, and that furnaces erected at Old Church Brickfield now deal with the refuse in a satisfactory manner.

Barnstaple.

Dr. J. R. Harper draws special attention to the lack of an isolation hospital and to the need for greater cleanliness of persons milking and distributing milk.

Thedwastre and East Stow.

Dr. S. C. Houndsfield reports that the isolation hospital used for these two districts and Stowmarket, which was in great demand for most of the year, is "in a bad way," and that unless something drastic is done in the way of rebuilding, the work cannot be carried on and the hospital must be closed.

"Audi alteram partem."

THE PAIN OF PSEUDO-ANGINA.

To the Editor of THE LANCET.

SIR,—In my paper on Angina Pectoris in THE LANCET of May 5th I referred to some experiments of Dr. E. P. Poulton in which a substernal oppressive pain was produced by artificially distending the oesophagus. Since then I have found that Stephen Hales¹ (who tested distensibility and fatigue of vascular coats, &c.) "found the gullet very distensible with a small force of water or wind," and that the gullet when dilated "compresses the descending aorta where the gullet is confined in its passage between that and the heart" (and so offers an explanation of vertigo). This observation is worth considering as a possible explanation of the particular class of quasi-anginal cases I described; and of the relief given by Mr. Verdon in angina by deflation of the stomach with a tube.

I am, Sir, yours faithfully,

Cambridge, May 11th, 1923.

CLIFFORD ALLBUTT.

L'AFFAIRE SPAHLINGER.

To the Editor of THE LANCET.

SIR,—Having been commissioned to investigate Mr. Spahlinger's treatment, I visited his Institute in Geneva, in company with medical men from other British Dominions, and came to the following conclusions:—

Spahlinger has developed his methods after a long period, some 16 years, of research work. The methods at present are vaccine and serum therapy. Spahlinger claims and proves conclusively that tubercle bacilli, under different conditions of temperature, environment, &c., give forth different toxins, many of which he is able to isolate either as exotoxins or endotoxins. The methods of preparation of his various antitoxins, &c., are very elaborate and involve the description of many brilliant mechanical methods, which have not been adopted elsewhere. By his preparation of vaccines, he can apparently produce an artificial immunity such as that acquired by most humans who go through the world resisting all tuberculous infections. This has been well worked out by animal experiments.

The vaccine, in addition to its curative effects, may be used for prophylactic purposes, producing a degree of immunity that will last for many years. This vaccine therapy is used in treatment of all cases where the disease has not advanced too far. I saw many patients who had been treated by vaccines, and in most cases the results had been very good. Above all, the use of vaccine therapy seems to be specially indicated in what is commonly called surgical tuberculosis—e.g., glandular enlargements and bone infections. Some of the results obtained were most instructive, as in the gland

cases the swellings had completely disappeared, with no evidence whatever of fibrous tissue response; from which one makes the inference that the cure resulted in the destruction of the bacilli rather than in the encapsulation by fibrous tissue.

The serum prepared by Mr. Spahlinger is a long process, and briefly the method is as follows: By the use of different processes he isolates different types of toxins of different chemical constituents and of profoundly varying degrees of virulence, as demonstrated by him in experiments both in vivo and in vitro. Each of these toxins is injected at varying intervals into separate horses over a period of one year. In addition he also prepares an immune serum against pneumococci and streptococci in order that mixed pulmonary infections may be combated. The sera from the different strains are mixed together to form his complete serum. The use of this is only indicated in advanced cases.

The methods of preparation are a model of thoroughness and scientific research. Everything is faithfully controlled and the findings filed. The preparation of the vaccine takes some nine to ten months, whilst the serum takes nearly four years. The course of treatment varies in different cases, whether vaccine or serum therapy or both are used. The vaccine course should not last more than six months, but it may be necessary to carry it on longer. The serum is only used when the conditions are severe.

I saw many patients that had been treated and many that were under treatment. The treatment appears to be most effective and almost dramatic in all cases and types of surgical tuberculosis, regardless of how long standing the condition may be. Pulmonary cases respond, but not so rapidly. Yet in many I could find no evidence of disease, although from trustworthy documentary evidence there had been gross lesions present.

One case shown was a young Englishman, who some eight months before had reached Geneva in a practically moribund state exhibiting extensive pulmonary tuberculosis in both lungs with ulceration of the larynx. Reliable West-end physicians had diagnosed these conditions. Under a course of vaccine with a short period of serum therapy the man had made a wonderful recovery, and when seen by me exhibited no evidence of tuberculous infection and was able to do a hard day's work.

My conclusions coincide with those of my colleagues. After carefully weighing over the evidence and fully realising how difficult judgment is in such cases, we are of the opinion that in his methods we have advanced into a realm quite unexplored by any other observers. We have no hesitation in stating that Spahlinger is working on lines which, if fully developed, will bring the treatment of tubercle into the same plane as the treatment of diphtheria, tetanus, and from the prophylactic aspect will give results as followed the administration of T.A.B. vaccine. Mr. Spahlinger's work is a great one and will, I am sure, if given sufficient light and support, do more to alleviate the sufferings of those afflicted with this disease and eradicate the tubercle bacillus in one year than all the present-day methods will do in 100 years.

I am, Sir, yours faithfully,

H. B. JEFFS, M.D. Toronto,
Immigration Medical Adviser, Canada.

THE ABUSE OF VENEREAL CLINICS.

To the Editor of THE LANCET.

SIR,—May I ask if THE LANCET is aware of the following facts concerning the venereal clinics and whether it proposes to use its influence to rectify these matters?

1. That these clinics are abused by a great many persons who can well afford to pay.
2. That the free treatment of diseases contracted by promiscuous sexual intercourse is a direct encouragement to vice and immorality.
3. That this is an injustice to the ratepayers and a waste of public money.
4. That many practices hitherto more or less dependent on the treatment of these diseases have depreciated in value, and in some cases ceased to exist, owing to the abuse of the venereal clinics.

I am, Sir, yours faithfully,
C. F. MARSHALL, M.D., F.R.C.S.

Welbeck-street, W., May 9th, 1923.

* * The report of the Trevethin Committee is expected to deal with the sound points raised by our correspondent. The feeling is undoubtedly widespread that patients who can afford it should pay for their treatment at the clinics, but no satisfactory method of compulsion has yet been devised. In some places instruction and warning are given as well as treatment, and where this is done as it should be there can be no question of encouragement to vice. Until practitioners generally are equipped to deal efficiently with venereal disease, we have repeatedly advocated a panel of practitioners through whom treatment could be provided.—ED. L.

SUBCUTANEOUS CALCAREOUS DEPOSITS.

To the Editor of THE LANCET.

SIR,—In THE LANCET for May 5th (p. 900) Dr. J. R. Logan is reported as having shown a case of subcutaneous calcareous deposits in the hands in an elderly female, suffering from a mild degree of Raynaud's disease. Most similar cases, as far as I am aware, have shown sclerodactylia of the hands, and sclerodactylia is often accompanied by angiospastic symptoms resembling mild Raynaud's disease. I would suggest that the case is of the same class as the one of sclerodactylia with subcutaneous calcareous concretions in a woman that I described, jointly with Dr. R. F. Scholefield, in 1911.¹ The patients are mostly females. In Haldin Davis's case there were "Raynaud-like" symptoms, but no definite sclerodactylia, when brought before the Dermatological Section of the Royal Society of Medicine in March, 1912. The publications on cases of subcutaneous calcareous concretions and "Kalksteingicht" have become very numerous. In France and Italy cases have sometimes been described under the heading "Profichet's disease" owing to G. C. Profichet's thesis "Sur une variété de concrétions phosphatiques sous-cutanées (pierres de la peau)," Paris, 1900. Considerably earlier was the writing by a Swiss doctor, H. Weber, on the subject. A recent paper of interest on "Kalksteingicht" is that of E. Holländer.²—I am, Sir, yours faithfully,
F. PARKES WEBER.

London, May 8th, 1923.

TREATMENT OF LIVER ABSCESS BY ASPIRATION.

To the Editor of THE LANCET.

SIR,—In their interesting paper on this subject in THE LANCET of May 12th Dr. P. Manson-Bahr and his collaborators refer to the method of evacuating a pointing abscess by means of a trocar, which was practised as long ago as 1828. So close and ingenious an approximation to this method was recommended by Aretæus, the Cappadocian, who flourished about the

¹ Brit. Jour. Dermat., 1911, xxiii., 276.

² Deut. med. Wochenschr., 1917, xliii., 431.

middle of the second century A.D., that I thought it might be of historical interest to quote the words of that great physician. The following sentences are from the translation by Francis Adams of the "Extant Works of Aretæus" (London: Printed for the Sydenham Society, 1856). Writing of liver abscess he says:—

"If the process incline inwardly, nature is far superior to the physician . . . but if it incline outwards, it is bad not to make an incision, for otherwise the liver is corroded by the pus, and death is not long deferred. But, if you intend to make an incision, there is a danger of hæmorrhage, from which the patient may die suddenly; for hæmorrhage in the liver cannot be checked. But if you are reduced to the necessity of making an incision, heat a cautery in the fire to a bright heat and push it down to the pus, for it at the same time cuts and burns; and if the patient survive, there will run out a white, concocted, smooth, not fetid, very thick pus, by which the fever and other bad symptoms are diminished, and altogether the health is restored."

Dr. Manson-Bahr also stresses the diagnostic importance of right shoulder pain, which we now believe to be due to involvement of the under surface of the diaphragm and reference via the phrenic to the fourth cervical area. With this symptom of hepatic abscess Aretæus was quite familiar, though his interpretation of it was different. In referring to inflammations of the liver, he states:—

"If it be converted into pus, a sharp pain possesses the parts as far as the clavicle and the tops of the shoulders, for the diaphragm from which the liver is suspended is dragged down by the weight, and the diaphragm drags the membrane lining the ribs to which it is attached, and this membrane (the pleura) is stretched up to the clavicle and the top of the shoulders, which also are dragged down."

He further recognises that the painful, difficult respiration which may be present is due to impairment of diaphragmatic movement . . . "for," he says, "the diaphragm does not coöperate with the lungs, by assisting them in contraction and dilatation."

I am, Sir, yours faithfully,

J. A. RYLE.

The Warden's House, Guy's Hospital, S.E., May 14th, 1923.

THE DOSE OF BAYER "205."

To the Editor of THE LANCET.

SIR,—In view of the dearth of experience at present available as to the dosage of Bayer "205," it may be worth while recording that as much as 5 g. have been given intravenously in 50 hours to a native of this country. There were no untoward symptoms, but although no readily recognisable albuminuria resulted the presence of a few casts in the urine could be detected for a month afterwards. During the last few months, however, no casts have been seen and the patient is back at work. The dosage suggested by Dr. G. C. Low and Dr. P. Manson-Bahr for the treatment of Europeans may require modification when the African native for whom the drug was prepared comes to be treated. His greater tolerance may enable him to receive a single curative dose of 3 to 5 g. or more. I am indebted to the courtesy of Dr. C. H. Hennings for placing a small quantity of the drug at my disposal.

I am, Sir, yours faithfully,

N. A. DYCE SHARP,

Kaduna, Nigeria, April 19th. West African Medical Service.

OTITIC MENINGITIS.

To the Editor of THE LANCET.

SIR,—In the report last week of my paper on Otitic Meningitis, read before the Section of Otology of the Royal Society of Medicine, there is an error which reads: "Otitic meningitis of the middle fossa and cortex of the brain was much more frequent than that of the posterior fossa." It should be infrequent. The large majority of cases of otitic meningitis commence in the posterior fossa, and involve the base of the brain.

I am, Sir, yours faithfully,

Harley-street, W., May 14th. EDWARD D. D. DAVIS.

Parliamentary Intelligence.

HOUSE OF LORDS.

THURSDAY, MAY 10TH.

Dangerous Drugs and Poisons Bill.

THE Dangerous Drugs and Poisons Bill was read a third time and passed.

HOUSE OF COMMONS.

WEDNESDAY, MAY 9TH.

International Labour Conference.

Sir M. BARLOW (Minister of Labour) moved: "That this House approves the policy of H.M. Government respecting the draft conventions and recommendations adopted by the third and fourth sessions of the International Labour Conference held at Geneva in 1921 and 1922 respectively." He said that the subject of the use of white lead in paint proved a very contentious one at the 1921 Conference. The workers pressed for an international effort along the lines of eliminating altogether what they held to be a serious peril in industrial life. On the other hand, evidence was adduced, both as to the greater effectiveness of paint containing white lead and also as to the possibility of minimising, if not eliminating, the peril to the worker if proper precautions were taken. The British Government had reserved freedom of action in the matter, and proposed to have further consultation and to take up, if necessary, with the labour organisation at Geneva the question of the amendment of the draft convention. Article 1 of which prohibits, with certain definite exceptions, the use of white lead or sulphate of lead in the internal painting of buildings; and Article 3 of which prohibits, with certain exceptions, the employment of males under 18 years of age, and of all females, in any painting work of an industrial character involving the use of white lead. The second recommendation at the 1921 Conference dealt with the protection, before and after childbirth, of women wage-earners in agriculture. This raised the whole question of the famous Washington Maternity Convention, which the Government had refused to ratify on the ground that we had already, under the National Health Insurance Act, and the Factory Acts, a scheme of this sort. The Washington Maternity proposals were, to some extent, more intensive, and the existing English provisions were clearly much more extensive. For each woman affected, the Washington provision would give rather more elaborate protection. For instance, they would require six weeks off work before and after confinement; while the analogous provisions of our Factory Act was four weeks off work after confinement. On the other hand—and this was the great difference—the Washington Maternity proposals only affected women who were themselves engaged in industry. In this country there were about 440,000 married women so engaged. But the English provisions under the Health Insurance Act covered, not only women engaged in industry, but the wives of employed contributors under the Act. Further, the Maternity and Child Welfare Act, 1918, and the schemes of local authorities under that Act, with the aid of the State grant, provided for the use of all women such services as midwives and doctors, post-natal treatment, supply of milk, and so on. In these circumstances, and for reasons similar to those which prompted the late Government to refuse to ratify the Washington Maternity Convention for industry generally, the Government did not propose to accept this recommendation. The Government proposed to accept the recommendation that women wage-earners in agricultural undertakings during the night should be given not less than nine hours, if possible consecutive, off work. It was proposed also to accept a recommendation of a similar character providing for not less than ten hours off work for children under the age of 14 years of age of either sex, and female young persons of between 14 and 18 years of age. On a division Sir M. Barlow's motion was carried by 235 votes to 176.

Milk for Infants and Children.

Mr. HOPE SIMPSON asked the Minister of Health whether he proposed to take any action in accordance with the recommendations of the Departmental Committee on Distribution and Prices of Agricultural Produce, recorded in para. 142 of their Interim Report on milk and milk products, with the object of stimulating the consumption of liquid milk by infants and children; and whether he would consult other departments concerned, including the Board of Education, in furtherance of this object.—Mr. NEVILLE CHAMBERLAIN replied: This matter is under consideration. I may, however, remind the hon. Member that a circular and pamphlet were issued by my department in October, 1920, in regard to the use of milk, in which advice was given as to the best

means of disseminating information on the special value of milk as a food, the desirability of largely increasing the consumption per head of the population, and the need for an adequate supply of fresh and pure milk.

The Cost of Slum Clearances.

Captain WEDGWOOD BENN asked the Minister of Health on what grounds he based his estimate of £230,000 as the money required to assist local authorities in slum clearance in any one year; and whether, if local authorities demanded a larger sum, the necessary estimates would be introduced.—Mr. NEVILLE CHAMBERLAIN replied: The estimate of £230,000 referred to in the memorandum explaining the financial provisions of the Housing Bill was the best estimate that could be made of half the annual deficit on schemes to be approved under Clause 1 (3) of the Bill which local authorities might be expected to carry out in the near future. If local authorities submit schemes which would involve in the aggregate a larger contribution from the Exchequer the matter will be further reviewed on the annual estimates.

Small-Pox in Doncaster.

Mr. BROMFIELD asked the Minister of Health whether he was aware that two cases of small-pox were recently removed from a street in Doncaster three weeks after vaccination had been performed in each case; and whether any other small-pox cases at Doncaster, or elsewhere, during the past two months had developed after recent vaccination.—Mr. NEVILLE CHAMBERLAIN replied: The answer is in the negative. I am informed by the medical officer of health that in no case has small-pox occurred in Doncaster after recent vaccination where the interval between vaccination and the development of the disease has exceeded 14 days; and I am not aware of the occurrence of any such case elsewhere during the past two months.

Minimum Salary for Health Visitors.

Mr. ALBERT BENNETT asked the Minister of Health if he could now make any statement for the guidance of local authorities as to the reasonable standardised minimum salary which should be offered by them to health visitors.—Mr. NEVILLE CHAMBERLAIN replied: The salaries of health visitors cannot be considered without reference to other analogous occupations, and the general question is still under my consideration. I am arranging that a deputation on the subject shall be received at my department shortly, when I hope that the situation will be further elucidated.

Dental Registration Fees.

Mr. SEXTON asked the Minister of Health if, in accordance with the statement of the chairman of the Dental Board in the House on March 8th, 1922, any attempt to lessen the annual fees demanded from dentists registered under the Dentists Act, 1921, was to be made in the year commencing January, 1924.—Mr. NEVILLE CHAMBERLAIN replied: The undertaking to which the hon. Member refers was an undertaking to reconsider the fee in two years' time from March, 1922. No undertaking was given that the fee would be reduced. I am informed that the Dental Board will duly consider the matter in accordance with the undertaking given by their chairman, but they are not yet in a position to come to a decision.

Overcrowding and Tuberculosis.

Mr. TREVELYAN asked the Minister of Health what proportion of the patients under the care of the London tuberculosis dispensaries lived in dwellings with one or two rooms only; and whether he intended to make any special provision for dealing with the overcrowding in the Metropolitan area.—Mr. NEVILLE CHAMBERLAIN replied: I have no information as to the first part of the question. As to the second part, overcrowding in the Metropolitan area will be automatically reduced as the erection of new houses proceeds.

Administrative Allowance of Approved Societies.

Sir KINGSLEY WOOD asked the Minister of Health when he proposed to lay before Parliament the draft of the regulation to reduce the administrative allowance of approved societies; and what opportunity would be afforded of Parliamentary discussion.—Mr. NEVILLE CHAMBERLAIN replied: The draft regulation referred to by the hon. Member will be published within the next few days and the regulation will be made and laid before Parliament as soon as the statutory period of 40 days has elapsed. There will be usual opportunities for Parliamentary discussion under the procedure whereby the regulation becomes operative unless within 21 sitting days either House signifies its disapproval.

Exemptions from Vaccination.

Sir WALTER PRESTON asked the Minister of Health what percentage of newly-born children were vaccinated in 1907; what percentage of children were vaccinated in 1922; and what was the total number of exemptions from vaccination granted in 1907, and the total number of exemptions in 1922.—Mr. NEVILLE CHAMBERLAIN replied: In 1907 70.9 per cent.

of the newly-born children were vaccinated; in 1921 the percentage was 38.3. The total number of exemptions from vaccination was 76,709 in 1907, and 382,155 in 1921. Figures for 1922 are not yet available.

Small-pox Statistics.

Mr. BECKER asked the Minister of Health if he could give figures showing the number of small-pox cases and suspected cases notified during 1921, 1922, and for the first three months of 1923.—Mr. NEVILLE CHAMBERLAIN replied: The following are the figures:—

Period.	No. of cases notified.	Other cases reported but not notified.	Cases subsequently withdrawn or not regarded as small-pox.	Net total of cases.
1921 ..	343	23	30	336
1922* ..	1042	17	80	979
1923† ..	533	5	18	520

* The figures are provisional, as full particulars of certain cases have not yet been received.

† First three months.

Infanticide.

Mr. WILLEY asked the Secretary of State for the Home Department whether, in view of the fact that in 1922 the Infanticide Act was passed providing that a woman charged with the murder of her infant child may, under certain conditions, be convicted of manslaughter, he could state how many women were now in gaol for offences which, had this Act existed at the time of their conviction, would have come under it; whether he would give the average term of imprisonment they had collectively suffered; whether the Home Office had reviewed all such cases; and, in that event, how many women had been released, how many had had their sentences reduced, and how many had not been notified of any concession whatever.—Mr. BRIDGEMAN replied: Only one woman convicted before the passing of the Infanticide Act and sentenced to death for the murder of her newly-born child is now in prison. She had served a previous sentence of 18 months for the manslaughter of another child. She has now served 26 months under her present sentence. Further interference with the sentence cannot yet be recommended.

Canadian Cattle and Tuberculosis.

Lieut.-Colonel FREMANTLE asked the Minister of Agriculture if his attention had been called to the report of the medical officer of health to the Manchester port sanitary authority to the effect that the first batch of Canadian cattle were not altogether free from pulmonary tuberculosis; and what steps were being taken to test imported cattle for tubercle infection and to exclude the importation or distribution of cattle so infected.—Sir R. SANDERS replied: The reply to the first part is in the affirmative. Canadian store cattle imported into this country are not required to undergo a test as to freedom from tuberculosis. Cattle affected with tuberculosis to a dangerous degree would be liable to be dealt with under the Milk and Dairies (Amendment) Act, 1922.

Post Office Medical Referees' Reports.

Mr. AMMON asked the Secretary to the Treasury whether he would consider introducing a regulation to enable Post Office employees appealing to a medical referee to be supplied with a copy of the referee's decision, for which the appellant pays.—Sir WM. JOYNSON-HICKS (Postmaster-General) replied: The referee's report is made in confidence; and there would be strong objections to its being communicated to the appellant. The deposit paid by the latter does not represent the referee's fee.

THURSDAY, MAY 10TH.

Appeal Tribunal Cases.

Mr. PIELOU asked the Minister of Pensions the number of cases brought before the House of Lords appeal tribunal, Birmingham, for the six months ending Dec. 31st, 1922, and also for the same period in 1921; and if he would state the result of these appeals.—Colonel GIBBS replied: During the six months ending Dec. 31st, 1921, eight tribunals sat at Birmingham. During the six months ending Dec. 31st, 1922, five tribunals sat at that centre. The results of the sittings during the two periods in question were as follows: (1) Six months ending Dec. 31st, 1921: Heard, 2746; allowed, 693. (2) Six months ending Dec. 31st, 1922: Heard, 1285; allowed, 312.

Lip-Reading and Ex-Service Men.

Captain BERKELEY asked the Minister of Pensions whether lessons in lip-reading were granted as of right to all ex-Service men suffering from deafness due to war service; whether he was satisfied that 25 lessons were sufficient to enable unlettered or backward men to acquire proficiency in lip-

reading; and whether, if cases could be brought to his notice of men who had been unable to learn lip-reading in the prescribed number of lessons, he would be prepared to increase the number of lessons in such cases.—Major TRYON replied: Where a man is likely to benefit by it, instruction in lip-reading is provided by my department. After a certain amount of instruction proficiency in lip-reading is entirely dependent upon regular practice, and it is the considered opinion of my advisers that a course of 25 lessons affords the man of average intelligence ample opportunity of acquiring the faculty. Experience has shown, however, that the unlettered man of less than normal intelligence is incapable of acquiring facility in the art. I shall be pleased to inquire into any individual cases if the hon. and gallant Member will let me have particulars.

Motor Cycle Pillion Accidents.

Mr. BURGESS asked the Secretary of State for the Home Department the number of serious and fatal accidents, respectively, which had occurred during each year since 1919, as a result of riding on the pillions of motor bicycles.—Colonel ASHLEY (Parliamentary Secretary to the Ministry of Transport) replied: No separate record is kept, either by the Home Office or by my department of accidents in which motor cycles with pillion riders are involved. Although the Minister of Transport is not vested with any legal powers in the matter, it is the practice of my department to hold informal inquiries and inspections into the circumstances attending all serious road accidents. There is no evidence, so far as these investigations go, that accidents on the nature referred to are particularly frequent, or show any tendency to increase in number.

Deafness among Children.

Mr. FOOT asked the President of the Board of Education the number of children in the special schools for teaching the deaf; and if there were any statistics to show the number of deaf children in the country for whom no educational provision was made.—Mr. E. WOOD replied: The accommodation in the certified special schools for the deaf is 4636. The latest returns from local education authorities show that there are approximately 6000 deaf and dumb and partially deaf children in the country. On the basis of these figures the provision for such children in special schools is deficient by about 1400 places.

Cost of Tuberculosis Treatment.

Mr. LEACH asked the Minister of Health the total amount spent by local authorities on tuberculosis treatment during 1922.—Lord E. PERCY replied: The gross expenditure of local authorities during the financial year ended March 31st, 1923, is estimated to amount to £2,813,610, exclusive of capital expenditure for which particulars are not yet available.

Death-Rate in Doncaster.

Mr. RILEY asked the Minister of Health what was the death-rate in the Doncaster rural area, and what was the infant mortality in this district.—Lord E. PERCY replied: In the year 1922 the death-rate in the Doncaster rural district was 12.2 per 1000 living, and the infant mortality-rate 89 per 1000 births.

Medical Officer of Health at Frizington.

Mr. GAVAN-DUFFY asked the Minister of Health if he would state what salary was paid per annum to the late medical officer of health at Frizington, Cumberland; if his salary was fixed by agreement; had the period stated in that agreement expired; if not, had he agreed to its cancellation, and, if not, why had the Minister of Health agreed to the appointment of a second medical officer of health before the agreement with the first one had expired or been properly terminated; could he state if the present medical officer of health for Frizington had any qualification in the public health service, and at what salary he had accepted the position.—Lord E. PERCY replied: The salary for this part-time appointment agreed between the Council and the medical officer of health was £130 per annum, rising by £5 per annum to £150. His appointment was terminable by the council without my consent at three months' notice, which was given to expire on March 31st last. The council advertised the vacancy at £100 per annum, and have had one applicant, who has not a diploma in public health.

MONDAY, MAY 14TH.

Medical Practice in the Colonies.

Lieut.-Colonel FREMANTLE asked the Under Secretary of State for the Colonies in which colonies it had recently been considered necessary to amend the ordinances regulating medical practice in order to enable persons not holding qualifications registrable in the United Kingdom to practise medicine; and whether this modification of the standard required for registration or licensing of medical practice had the approval of the Secretary of State for the Colonies.—

Mr. ORMSBY GORE replied: The only three colonies in question (including dependencies) are British Honduras, Turks Islands, and St. Vincent. His Majesty has not been advised to disallow the ordinances in question, but in two of the three cases the governor has been instructed not to use the power conferred upon him without previous reference to the Secretary of State except in emergency. The Secretary of State attaches great importance to the maintenance of a high standard of professional qualification in the colonies, but he recognises that there may be circumstances in which rigid adherence to the rules in force in the United Kingdom are impracticable in some of the poorer or less developed communities.

Medical Officers in West Indies.

Lieut.-Colonel FREMANTLE asked the Under Secretary of State for the Colonies what payment had been made to the medical officers in the West Indian Colonies who have carried out treatment of yaws on an intensive system during the past four years; and what saving to the revenue had been effected by closing the hospital in Granada owing to the success of this treatment.—Mr. ORMSBY GORE replied: The medical officers in Granada undertook to perform this work without additional remuneration; but, as the committee appointed to inquire into the Windward Island Medical Service have recommended that some special allowance should be granted, the matter, together with the other recommendations of the committee, is receiving consideration. The Yaws Hospital was closed at the end of 1921. The cost in that year was £902; but as a certain amount of treatment is still being carried out, I am unable to say what proportion of this sum represents a saving.

Gas-poisoning Experiments.

Mr. LANSBURY asked the Under Secretary of State for War what species of animals were being used in gas-poisoning experiments at the Porton experimental station, near Salisbury: how many animals had been employed in the research since Feb. 23rd, 1922, when the figures were given in reply to a question by Mr. J. F. Green; and whether any of the experiments had consisted in dropping bombs containing poison gas among these animals.—Lieut.-Colonel GUINNESS replied: The species and numbers of animals which have been employed in the experiments referred to since Feb. 23rd, 1922, are as follows: cats, 66; goats, 48; guinea-pigs, 118; mice, 148; monkeys, 23; rabbits, 139; rats, 209. None of the experiments have consisted in dropping bombs containing poison gas among these animals.

Open-air Schools for Children.

Mr. FOOT asked the President of the Board of Education the number of local education authorities who had established open-air schools for the reception of children suffering from physical disability, and the total number of such schools now established throughout the country.—Mr. E. WOOD replied: Twenty-nine local education authorities have established 37 day open-air schools, and nine have established 13 residential open-air schools. In addition, voluntary managers have established 12 residential open-air schools; making a total of 62 open-air schools in England and Wales.

Alleged Contraventions of Lunacy Act.

Mr. THOMAS GRIFFITHS asked the Attorney General whether any steps had been taken by the Board of Control to inquire into the number of instances in which the managers of mental institutions run for profit had themselves taken measures, in contravention of the Lunacy Act, to summon doctors and magistrates for the incarceration of voluntary boards; and in the case in which one such offence had been brought to light in the Law Courts had any disciplinary measures been resorted to by the Board to check the recurrence of abuse.—Mr. NEVILLE CHAMBERLAIN replied: The Board of Control have no record of any instance in which such action has been taken in contravention of the Lunacy Acts.

Dentists Act Amendment Bill.

The Dentists Act, 1921, Amendment Bill, introduced by Lieut.-Col. Dalrymple White, which provides that the age of ex-Service candidates for qualification as dentists shall be reduced from 23 to 21 years, was read a second time.

TUESDAY, MAY 15TH.

Medical Service in the Army.

Lieut.-Colonel FREMANTLE asked the Under Secretary of State for War if he was aware that, owing to discontent in the Royal Army Medical Corps, especially among the better qualified officers, many of the best had already resigned and others were prepared to send in their papers; and what steps he proposed to take to avoid such weakening of an essential arm of the service.—Mr. GWYNNE replied:

I am aware that an unsettled feeling has been caused in the army generally by uncertainty as to the future establishment and rates of pay, and by the conditions of service that have prevailed during the period of reconstruction after the war. In the case of medical officers the attractions of the civil profession have doubtless reinforced these causes. It is hoped that the army will now be able to return to normal settled conditions, and it is not proposed at present to take any special steps in regard to the Royal Army Medical Corps.

Neurological Hospital at Saltash.

Mr. FOOT asked the Minister of Pensions when the premises of the Queen Alexandra's convalescent centre at Saltash were to be used for the treatment of neurasthenic patients, and the number of such patients who were to be treated there.—Captain CRAIG replied: It is hoped that these premises will be ready for the accommodation of about 400 neurasthenic patients in the course of the next two months.

Medical Certificates and the Drug Habit.

Sir EDWIN STOCKTON asked the Secretary of State for the Home Department whether, in view of the increase of the drug habit, he was in possession of any information to show that there was any abuse of medical certificates containing drugs which did not contain words prohibiting repetition; and, if so, whether he would take any action thereon.—Mr. BRIDGEMAN replied: The regulations made under the Dangerous Drugs Act expressly provide that the drugs shall not be supplied more than once on the same prescription, with an exception for cases in which the prescription explicitly directs that the drugs may be supplied at specified intervals on not more than three occasions; and, in view of this, the Committee which considered the regulations thought it unnecessary to require that the words, "not to be repeated," should be inserted in the prescription. To obtain or supply drugs on a prescription otherwise than in accordance with the regulations is an offence against the Act; and I have no reason to think that the regulation in question is not generally observed.

Medical Officers of Pensions Ministry.

Mr. CAIRNS asked the Minister of Pensions what were the names, grade, and salary of the 33 whole-time medical officers in the employ of the Ministry who had not served in the forces of the Crown; where they were employed; and whether action would be taken to replace these officers by men who served in the great war and in consequence suffered financial loss.—Captain CRAIG replied: I regret that in the answer which I gave last week the number of non-Service medical officers was overstated, the correct number being 31. It is, and always has been, the policy of the Ministry to give preference to ex-Service candidates for appointments whenever that course can be followed consistently with due regard to efficiency.

DONATIONS AND BEQUESTS.—The late Mr. William Howard Palmer, of Wokingham, Berks, left by will £3000 to the Royal Berkshire Hospital.—Among other bequests the late Miss Anne Louisa Black, of Castle Bank, Cupar, Fife, left £1000 (in her own memory) of which the income is to be applied by the Sick Nursing Society and Women's Guild of Cupar in providing food and clothing on the lines of the Samaritan Society and for small pensions to deserving women; £1100 for division between the Royal Infirmary, Edinburgh, and the Longmore Hospital; £1000 (in memory of her late brother Dr. Alexander Black) upon trust to apply the income in the provision of bursaries, scholarships, library books, or other purposes in connexion with the Royal College of Physicians, Edinburgh; £500 to the Adamson Cottage Hospital, Cupar, for an Anne Louisa Black bed for women and children; £500 to the Sick Children's Hospital; £500 to the Royal Blind Asylum for the training of men blinded in the war; and £100 to the Dundee Royal Infirmary. Certain residues of the property will go to the Sick Nursing Society, Cupar; the Edinburgh branch of the National Society for the Prevention of Cruelty to Children; the Edinburgh Royal Infirmary, and other charitable institutions.—Among other bequests the late Mrs. Mary Alice Clegg, of Alston Lodes, Waterhead, Oldham, left £1000 to the Oldham Royal Infirmary; £250 each to St. Dunstan's Blinded Soldiers' Fund, Oldham Poor Children's Holiday Fund, and the Society for the Prevention of Cruelty to Children; £100 to the R.S.P.C.A. The residue of the estate, if not exceeding £8000, to be divided between the Oldham Educational Committee for Scholarships, and for certain schools.—Lord Glendyne has given £200 in response to the appeal for £30,000, urgently required by the Cancer Hospital, Fulham-road, for the fitting up of an operating theatre and for structural alterations.

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—An extraordinary Comitia of the College was held on May 10th, the chair being taken by Sir Humphry Rolleston, the President. The following were admitted as Fellows, having been elected to the Fellowship at the last Comitia: Drs. R. Hingston Fox, J. Porter Parkinson, D. G. Hall, W. S. Fox, F. E. Tylecote, J. Owen, L. G. Parsons, John Parkinson, A. H. Gosse, and P. H. Manson-Bahr. The following were nominated by the Council: Sir Hugh Kerr Anderson, M.D., and Dr. Byrom Bramwell. A letter was read from Dr. J. J. Perkins resigning his examinership in medicine as from July next. A report was received from Dr. Drewitt, who represented the College at the bicentenary of the death of Sir Christopher Wren. A vote of thanks for his services and for his report was accorded to Dr. Drewitt. Dr. Edwin Goodall was appointed a representative of the College at the University of Wales vice Dr. H. W. G. Mackenzie resigned. The thanks of the College were accorded to Dr. Mackenzie. An address to His Royal Highness the Prince of Wales, President of St. Bartholomew's Hospital, on the occasion of the 800th anniversary of its foundation, was sealed. The President then dissolved the Comitia.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—An ordinary Council meeting was held on May 10th, with Sir Anthony Bowlby in the chair. Surgeon Vice-Admiral Sir Robert Hill was introduced and was admitted a Fellow of the College. A report from the Court of Examiners respecting candidates found qualified for the diploma was read, and diplomas were granted to 155 candidates mentioned in the report. A report was read from the Secretary to the Conjoint Examining Board respecting candidates found qualified for the Diploma in Public Health, and diplomas were granted, jointly with the Royal College of Physicians, to 20 candidates mentioned in the report. A report was read from the Secretary to the Conjoint Examining Board respecting candidates found qualified for the Diploma in Tropical Medicine and Hygiene, and diplomas were granted, jointly with the Royal College of Physicians, to 10 candidates mentioned in the report. Mr. Hugh Lett, F.R.C.S., was elected a Member of the Court of Examiners. A letter was read from the Clerk to the Barbers Company stating that the Court of the Company had resolved that, subject to the consent of the Royal College of Surgeons, the Thomas Vicary lecture should be continued for a further period of five years. The Council agreed to accept the offer.

A HOSPITAL FOR RICKETS NEAR DUBLIN.—A committee has been formed in Dublin, under the chairmanship of Dr. Ella G. Webb, for the purpose of establishing a hospital for rickets near Dublin. At present the accommodation for children in the special and general hospitals of the city is sufficiently taxed, and there is no institution specially suitable to deal with cases of rickets. A lady has offered the committee £5000, and it is believed that if another £5000 can be obtained there will be enough to meet initial expenses. Near Dublin there are plenty of sunny sites with sea or mountain air suitable for treating such cases.

MANCHESTER AND DISTRICT RADIUM INSTITUTE.—At the annual meeting held in Manchester on May 10th the chairman expressed his appreciation of the fact that the Institute was progressing satisfactorily in every way except financially. The expenditure has exceeded income by several hundred pounds, though the cost of radium has fallen by about 40 per cent. During 1922, 799 persons presented themselves at the Institute with a view to radium treatment; 514 emanation plates and 1281 emanation tubes were made during the year, and 59 cases of malignant disease, exclusive of rodent ulcer, were rendered free from signs and symptoms of disease. The total number of malignant cases treated was 584, and the usual average of something over 10 per cent. of perfect immediate results had been maintained. The number of rodent ulcers treated was 85, and 41 had apparently been cured, in addition to 15 patients suffering from non-malignant conditions. The attendances were 4000 of out-patients and 912 of in-patients. It was also stated that Dr. J. Holker had studied the effects of alpha, beta, and gamma rays on serum. These rays, it was found, had a marked effect on serum and on its colloidal condition—a condition for the determination of which by a special technique only a very small quantity of blood was required. The colloidal changes in blood due to absorption of a vaccine injected subcutaneously could be followed by this method. A natural extension of this work would be to follow the colloidal changes in blood due to the absorption of the products of the destruction of a tumour in a patient who was treated by radium.

INDIAN MEDICAL SERVICE: ANNUAL DINNER.—This dinner will be held on June 20th, at 7.45 P.M., at the Trocadero Restaurant, London, W. 1.

ST. PAUL'S HOSPITAL.—The annual board of governors will be held at the "Pickett-Thomson" Research Laboratory, St. Paul's Hospital, Endell-street, London, W.C. 2, on Wednesday, May 23rd, at 4 P.M.

UNIVERSITY OF MANCHESTER.—Prof. J. S. B. Stopford has been appointed Dean of the Medical School from September next in succession to Prof. R. B. Wild. A ceremony for the conferment of degrees in the Faculty of Medicine will be held on July 14th.

UNIVERSITY OF DURHAM COLLEGE OF MEDICINE, NEWCASTLE-UPON-TYNE.—The new building for the Bacteriological Department will be opened next Friday, May 25th. Visitors will be received by Sir David Drummond, president of the College of Medicine, in the King's Hall, Armstrong College, at 4.30 P.M., and at 5 P.M. an address will be delivered by Sir Frederick Andrewes in the Physics Lecture Theatre. The opening and inspection of the new building will follow.

LLANDRINDOD WELLS OPEN MEDICAL GOLF CHALLENGE CUP.—This event was played off on May 2nd, 3rd, and 4th. The winner was Dr. D. Saunders Jones, who beat Dr. F. C. Hunot, the winner last year, by 6 and 5. Lady Mayo Robson presented the cup and replica. The competitors were entertained to luncheon at the Golf House by the local committee. Toasts were proposed and responded to by Dr. Jones-Evans and Dr. Baird, who spoke highly of the claims of Llandrindod as a health resort.

WELLINGTON (N.Z.) GENERAL HOSPITAL.—At a meeting of the Hospital Board held on March 22nd it was decided to provide over a three-year period a sum of £150,000 to remodel and extend the hospital, the additions to include a new admission block and a new genito-urinary block. If the board could establish its right to incur such expenditure, it was agreed to send the medical superintendent, Dr. D. McD. Wilson, on a visit to the U.S.A. and Canada, in order to study the latest hospital methods.

COURSE ON MEDICAL HYDROLOGY.—This course, already announced as taking place from May 29th to June 2nd, will include lectures at the University of London, South Kensington, and demonstrations at the National Institute for Medical Research, Hampstead, at the Special Surgical Hospital at Shepherd's Bush, and at Harrogate. Medical students interested in physical methods of treatment are invited to avail themselves of the course, without fee. Those who propose to attend are asked to send their names, preferably before May 21st, to the Hon. Secretary, Dr. W. Edgecombe, c/o University Extension Department, University of London, South Kensington, S.W. 7.

ANCOATS HOSPITAL, MANCHESTER.—At the ninety-fourth annual meeting it was stated that there was still a deficit of £8000 on the new nurses' home. The number of in-patients in 1922 was 2307, compared with 2194 in the year before, and of out-patients 8937 compared with 9132; accident cases numbered 18,912, against 17,361; 1329 major operations were performed, against 1139 in 1921; and 477 minor operations, against 722. Attendances at the X ray department 3395, compared with 3156. There was a decrease of £2938 in income, attributable to the severe trade depression, but the workpeople's contributions continued to be maintained. Expenditure showed a reduction of £3691.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—The report for 1922 will be submitted to the annual meeting, which is to be held at 11, Chandos-street, London, W. 1, on May 23rd at 5 P.M. Since the last report seven new members have been elected and four have been lost owing to death and resignation. The Society now consists of one honorary, 166 life, and 139 ordinary members, making a total of 306. During the year the Society has suffered the loss of its President, the late Sir Alfred Pearce Gould, Dr. F. de Havilland Hall being elected to take his place. The invested capital of the Society now stands at £146,650; under the by-laws only income may be used for the payment of grants and expenses. The income from investments amounted to £4744, £321 was received from subscriptions and donations, making a total income of £5065; the working expenses were £335. During the year three widows came on the funds and three died; on Dec. 31st, 1922, there were 51 widows and four orphans in receipt of grants. £4407 10s. was distributed in grants during the year. The income limit for widows has been raised from £100 to £125, and that of orphans from £50 to £60, so that in future any widow of a member left with an income of £125 or under and any orphan with an income of £60 or under, is eligible to receive a grant from the Society.

GRESHAM LECTURES ON PHYSIC.—Sir Robert Armstrong-Jones will deliver four lectures at Gresham College, in the City of London, at 6 P.M., on Tuesday, May 22nd, and the three days following. The subject will be Medical Hydrology and Hydropathy, with special regard to the climate of health resorts in England and Wales. The lectures are free to the public.

MEDICAL GOLFING SOCIETY.—The annual summer meeting of this society will be held at Addington Golf Club on June 14th. All medical men on the Register are eligible for membership of this society. Entries for the meeting must be accompanied by the annual subscription of 10s., if due, and should be sent, with lowest handicap, to the hon. secretary, Dr. Rolf Creasy, jun., 25, Devonshire-place, London, W., on or before Monday, June 11th.

SOUTHAMPTON AND DISTRICT ANNUAL MEDICAL DINNER.—The fourth dinner was held on May 9th at the South Western Hotel, Southampton, and was well attended. The chairman, Dr. G. S. Farquharson, made a reference to the late Dr. W. P. Purvis, whose memory was honoured in silence. A musical programme was supplied by Mr. Leonard Munn and Dr. H. L. Hamilton, and a very entertaining evening was spent.

INVERNESS HOSPITAL.—The annual report states that the total number of patients for the year was 869 in-patients and 400 out-patients, a considerable number of the latter being discharged soldiers and sailors. H.M. the Queen visited the hospital on August 24th, when she inspected the children's wards and other parts of the institution. The year opened with a debt of £2762 and closed with a balance of £1569, the apparent improvement being due simply to the withdrawal of capital which had been necessary to meet deficiency in revenue for some years.

HERTFORDSHIRE COUNTY SANATORIUM.—On May 7th the new sanatorium established by the Hertfordshire County Council at Ware Park, near Hertford, was opened by the Marchioness of Salisbury. Sir George Newman, Chief Medical Officer of the Ministry of Health, stated in the course of a short speech that although 100 persons a day died of what John Bunyan called "the captain of the men of death," there was undeniable evidence that tuberculosis was curable for the large proportion of the population affected by it, to the extent, at least, that they might be restored to a long period of useful life. In 1850 the deaths were 3200 per million, but the number was now 800, or a reduction to one-fourth in about 70 years.

ROTARY INTERNATIONAL ASSOCIATION: A SECTION OF MEDICINE AND PHARMACY.—At the invitation of Councillor George Whitfield, who is himself a pharmacist, 20 Rotarians connected with pharmacy, medicine, and allied professions met at the Mayor's parlour, Scarborough, on May 9th, for the purpose of constituting a vocational section. Dr. T. Stephenson, of Edinburgh, interim convener, occupied the chair. It was decided to include registered pharmacists, together with the allied professions of medicine, dentistry, veterinary surgery, and analytical chemistry. Dr. Stephenson was elected chairman for the ensuing year, and Mr. Kenneth McLennan, of Edinburgh, was appointed hon. secretary to the section. An executive was elected, consisting of the chairman, with Major E. Saville Peck (Cambridge) and Sir T. Robinson (Dublin). The first regular meeting of the section will be held in London in July, during the British Pharmaceutical Conference.

"AMBULANCE."—Hitherto the only publication issued by the College of Ambulance has been a small booklet brought out each term. Last month saw the first issue of a new quarterly magazine entitled *Ambulance*, which will supersede the former publication, and is intended to be not only a chronicle of the work of the College, but also a link between all at home and abroad who are interested in the various subjects which may be grouped together as ambulance work in general. Sir James Cantlie contributes an article on the Origin of Ambulance Work; Dr. W. Salisbury Sharpe writes of the Use and Abuse of Tourniquets, and Dr. F. R. G. Heaf of the Tuberculous Patient's Life After the Sanatorium, whilst the "Bookshelf" is arranged by Dr. T. N. Kelynack. Amongst other contents of interest are an article on Pestology by Mr. A. E. Moore, director of the Incorporated Vermin Repression Society; an account of a Sudan cholera camp during Kitchener's Nile campaign of 1896, by Mr. E. F. Knight; and a sketch entitled *Medicine Men*, by Mr. E. E. Bond, who indicates the value of knowledge of first aid in an uncivilised and, in this instance, a tropical country, beyond the sphere of qualified medical practice. We wish this new venture a wide success in its work of education towards public health. The magazine is to be obtained only at the College of Ambulance, 56, Queen Anne-street, Cavendish-square, London, W. 1. Annual subscriptions, 2s. 6d. Single copies, 6d., post free 8d.

MEDICAL SOCIETY OF LONDON: ONE HUNDRED AND FIFTIETH ANNIVERSARY.

THE one hundred and fiftieth anniversary of the founding of the Medical Society of London was celebrated by a dinner at the Hyde Park Hotel on May 15th, the Prince of Wales being the principal guest. Lord Dawson of Penn, President of the Society, occupied the chair, and there were present prominent representatives of the learned, scientific, and artistic professions, including—

The Lord Chief Justice (Lord Hewart), Viscount Astor, Viscount Burnham, Viscount Gladstone, Viscount Knutsford, Lord Kenyon, Lord Riddell, Lord Justice Atkin, Mr. Lloyd George, Mr. Neville Chamberlain, Sir W. M. Abbott-Anderson, Sir T. Clifford Allbutt, Sir Charles Allom, Mr. Donald Armour, Sir Charles Ballance, Sir P. W. Bassett-Smith, the Bishop of Birmingham, Prof. Blair Bell, Sir David Bower, Sir Charlton Briscoe, Sir John F. H. Broadbent, Prof. C. K. Clarke (Toronto), Sir Frank Colyer, Sir Maurice Craig, Sir Anderson Critchett, Prof. E. Emrys-Roberts, Sir Crisp English, Sir Walter Fletcher, Dr. Herbert Morley Fletcher, Sir Robert Fox-Symonds, Sir Archibald Garrod, Lieut.-General Sir John Goodwin, Sir Robert Hadfield, Sir E. Marshall-Hall, K.C., Sir William Hale-White, Sir William Hamer, Surgeon-Vice-Admiral Sir Robert Hill, Sir Arthur Holbrook, Sir Thomas Horder, Sir Robert Jones, Sir Arbuthnot Lane, Sir Arnold Lawson, Major-General Sir William Leishman, Sir John Lynn-Thomas, Sir John MacAlister, Sir Frederick Mott, Mr. C. A. McCurdy, K.C., M.P., Sir George Newman, Sir William Orpen, Sir Charles Parsons, Sir Cooper Perry, Sir Arthur Pinero, Sir Richard Powell, Sir D'Arcy Power, Sir James Purves-Stewart, Sir James Reid, Sir Arthur Robinson, Sir Milsom Rees, Sir Hugh Rigby, Sir Leonard Rogers, Sir Samuel Sheaf, Sir Charles Sherrington, Lieut.-General Arthur Sloggett, Sir Squire Sprigge, Sir Arthur Stanley, Mr. St. Loe Strachey, Sir Harold Stiles, Sir C. Gordon-Watson, Sir Aston Webb, P.R.A., Sir Dawson Williams, Sir J. Thomson Walker, Sir William de C. Wheeler, Dr. Douglas Webster, Sir Alfred Yarrow, and many other well-known members of the medical and other professions.

The toasts of the King and the Queen, Queen Alexandra, and the other members of the Royal Family having been duly honoured, the PRESIDENT gave the toast of "Our Principal Guest, H.R.H. the Prince of Wales" and in doing so remarked that his Royal Highness followed the traditions of his illustrious ancestors in his interest in medicine both as a branch of learning and as an instrument for promoting the health of the nation. In anything which appertained to the interests of our hospitals and their work they might always rely upon his encouragement and support. That interest owed its strength to an appreciation of the other man's difficulties to a kindly feeling for human frailty—qualities which brought unity and goodwill among men.

The PRINCE OF WALES, in replying, said that it was a common boast among members of the medical profession that they practised the oldest science known to man. It was almost impossible to imagine an age so fortunate as to need no doctors, and probably the only reason why there were no doctors in the Garden of Eden was that Eve obviously knew the familiar prescription. "An apple a day keeps the doctor away." As one who had had a long experience of the kindness of heart characteristic of members of the medical profession, his Royal Highness said he should be ungenerous if he did not feel thoroughly at home in such a company as the present. Nobody who had had as much to do with hospitals, military and civil, as he had could have failed to discover that there was something about the art of healing which had a particularly good effect on those who practised it. Whether in a regimental mess or a ship's ward—

room, whether a hospital man or a general practitioner, the doctor was always a man of many friends. Speaking of the general practitioner, he would like to pay him a special tribute. He was a very devoted, and sometimes unrecognised, friend to the community. On him, in the long run, the health and well-being of the community depended, and in his hands to a great extent lay the honour of the profession as a whole, since for the majority of people he was the only representative of it with whom they came in contact. He, the Prince of Wales, was glad to see present three distinguished physicians from the United States of America. Being one of their fellow guests, he could not welcome them to the gathering, but as a real and sincere friend of America he welcomed them to our country.

The Prince of Wales then proceeded to point out a close connexion between such a Society as that whose one hundred and fiftieth birthday they were celebrating, and the national institution which he was always proud to help to the best of his ability—our national hospital system. The Medical Society was founded in 1773, towards the end of a century in which every branch of thought was growing with almost tropical rapidity. The very fact of its foundation was a proof of the intellectual development of medicine, showing that it was passing from the twilight of quackery into the clear light of science. The progress of medicine always went hand in hand with the development of the hospital system, and just about this same date—the dawn of modern medicine—there sprang up in London a cluster of hospitals whose names were household words to-day—Guy's, St. George's, the London, the Middlesex, Queen Charlotte's, and others. And although that period, 150 years ago, was more remarkable for a series of those purely scientific achievements, without which medicine could not exist, yet throughout its history the growth of the Medical Society of London, and others like it, had moved on parallel lines with the growth of the modern hospital system as we knew it to-day. To most of those who stood outside the temple of medical science, the real significance of what went on inside was only intelligible by the concrete results which that system showed. Medical research was valueless to humanity, unless humanity could benefit practically by it. Brilliant doctors like Lister would have laboured in vain, unless there had been some medium through which the fruits of their labour could be broadcasted, so to speak, to the great mass of the sick and the suffering among the community. The hospitals were such a medium. They are at once universities and the workshops of medical science; the centres to which come both the doctor to get further technical knowledge, and the patient to get his share of its practical application. Without the hospitals, medical science would be, comparatively speaking, a barren thing. Consequently, the value of such a Society as this, from a national point of view, depended very largely on its relationship to the hospital system, and by that the public judged it.

The Medical Society of London owed its origin to the same quickening of interest in the common health which impelled Londoners of the later eighteenth century to enlarge the hospital system. It had grown up alongside it, and had never failed to be to it a loyal and helpful friend. Directly and indirectly, the Society as a whole and its individual members had proved this many times over.

MR. LLOYD GEORGE proposed the toast "Medicine and the Medical Society of London," coupling with it the name of Lord Dawson. Since the Society was founded there had been very great changes. It was only about 40 years before the founding of the Society that the barber and the surgeon separated. That was a very good indication of the state of medical science before the founding of this great Society. Immediately before that date the art of destroying human life had been perfected by scientific men from generation to generation, but the art of saving life had hardly moved. Science had been called in for destruction; science was regarded almost as an

intrusion when it came to the saving of life. Since then there had been almost incredible changes. There had been an age of unlocking the secrets of nature, and no profession had responded more readily to it than the medical profession. There was a time when the human body was like a lamb which is the prey of bandits—roving, skulking in recesses, issuing forth to pillage and to slay with impunity. The strong could resist; the weak invariably fell. Medical science helped; medical science hindered. Even the most expert did not know who the bandits were, where they came from, what they were like, how to deal with them. At last the whole dark continent of disease has been explored. These pirates have been discovered. They have been ticketed, they have been identified, they have been blacklisted, they have been tracked to their lair, and in the majority of cases they are exterminated for the benefit of mankind. More than that, the gathering grounds had been dealt with. It was a great thing that medical science had done; it had given human life a better fighting chance with the odds in its favour as long as the military age, in the medical sense, lasted.

His Royal Highness had referred to the work of the hospitals. One of the greatest tributes ever given to hospitals was given by King Edward VII., who, when Prince of Wales, was seriously ill. Sir William Gull, when he went to him, said: "You, Sir, are as well cared for as if you had been in hospital." The poorest men in the land get that care. The richer may get it, but I have doubts about the classes between. Medical science owed a great deal to hospitals, and it was right to remind the nation of that, at a moment when they are struggling with the adversities following the war, and when they have a heavy burden of debt. But the greatest advance of all in medical science was the advance it had made in preventive medicine. Recent history had taught us that it was a difficult, dangerous, and costly enterprise to expel an invader once he had a grip upon the soil, and that even if we succeed in expelling him, he left behind a devastated area which it took years to repair. That was equally true of human life and the human frame. Preventive medicine put up defences and kept the enemy from attacking and breaking through. The great business men of the world, like the Chinese, knew that it is better to pay your doctor to teach you how not to get ill than to pay him for getting you well. What was true of the individual was equally true of the community, and the great advance, in his judgment, which had been made was in sanitation, in water, in food, in the teaching and inculcation of habit; above all in the housing of the people.

LORD DAWSON, in responding, after referring to the history of the Society of which he was the President, said that medicine was not only based on an increasing range of sciences, but it was permeated by the scientific spirit, and there was an enthusiasm for research to a degree hitherto unknown. Men realised that if they were to do justice to themselves they must ever be weaving the thread of the sciences into the web of their art. Medicine had extended its realm from observation to precise investigation. The greatness of its progress was instanced by our knowledge of infection, immunity, asepsis, hormones, internal secretions, metabolism, and the like, and the conquest of malaria, yellow fever, and other tropical diseases. Further, investigation was organised, its results were collated, and its benefits made available. And here they owed a tribute to the Medical Research Council, the founding of which was due to Mr. Lloyd George. A striking example of a great discovery launched in the right way through the medium of this Council was insulin. Lord Dawson here paid a well-deserved tribute to the achievement of their distinguished colleagues at Toronto, who, by coördination between laboratory and ward, by results tested in selected hospitals in Canada, Great Britain, and the United States, with careful control by the Medical Research Council to secure efficient production, had put before the world a reliable remedy which would

give a considerable control of a fell disease. More than that, new encouragement would thus be given to the patient and never-ceasing endeavour to conquer the mystery of that great scourge cancer, which had so far baffled a multitude of distinguished workers in many countries. Discussing the statesmanship needed if medicine was to bring its gifts to the service of man, Lord Dawson said that medicine, to do its work, required equipment and the resources of special branches of knowledge, such as radiology, bacteriology, chemistry. To bring these advantages within reach of the general practitioner was a pressing problem which must receive all the help possible in its solution. The teaching hospitals were another aspect of the same problem, and their maintenance was a national concern. On them depended not only the future of doctors and nurses, but the setting of a high standard of work. To starve them was to damage the whole nation. The aim of statesmanship for medicine should be organisation along with freedom of thought and that liberty in action without which no science could do its work.

Sir JOHN BLAND-SUTTON, proposing in an amusing speech "Sister Professions and Guests," showed how the medical profession was ancillary to every other profession and the other professions to it. He hoped that the presence of ladies as guests that evening was an augury that during Lord Dawson's régime the barrier which prevented women from being members of the Medical Society would be removed.

Lord HEWART, Lord Chief Justice of England, responded for the Law, and Mr. NEVILLE CHAMBERLAIN, M.P., as Minister of Health. The latter remarked that his department desired to bring the great advances made in medicine and surgery within the reach of all, but new appliances and methods of treatment added to expense, and the problem was how to keep our great institutions fully equipped and abreast of the times without at the same time killing the sources from which magnificent voluntary contributions had come in the past. That problem had not yet been solved, but he was convinced that they would solve it in time.

Appointments.

BUTCHER, T. B., M.R.C.S., L.R.C.P. Lond., has been appointed Civil Surgeon, Muttra, U.P., India.
CARLETON, H. H., M.D., B.Ch. Oxf., M.R.C.P. Lond., Honorary Assistant Physician to the Bristol General Hospital.
CHRISTIE, G. W., F.R.C.S. Edin., Certifying Surgeon under the Factory and Workshop Acts for Ulverston.
CLEGG, S. J., M.D. Manch., D.P.H., Medical Officer of Health for Durban, South Africa.
ELISON, J., M.B., B.Ch. Camb., F.R.C.S. Edin., Out-patient Surgeon at Chelsea Hospital.
FINCH, E., M.D., M.S. Lond., F.R.C.S. Eng., to a Lectureship in Surgery at the University of Sheffield.
ROBERTSON, J., M.B., M.S. Glasg., D.P.H., M.R.C.P. Edin., F.R.I.P.H. Lond., Medical Officer of Health, School Medical Officer, and Medical Superintendent of Infectious Hospital at Darwen.
WILLOCK, EDITH F., M.B., B.Ch. Dub., B.A.O., D.P.H., Resident Medical Officer, Manchester Babies' Hospital.

Medical Referees under the Workmen's Compensation Act:
MARTIN, H. O., L.R.C.P. & S. Edin. (Roxburgh County);
ROBERTS, H. H., M.D. Edin. (Haddington County);
RENWICK, T. D., L.R.C.P. & S. Edin. (Dunfermline District and Kinross County); DONALD, H. C., M.B. Glasg., F.R.C.S. Edin. (Paisley District); BROADFOOT, J., M.D. Glasg. (Ross and Cromarty (Mainland) and Dingwall and Tain Districts); SUTHERLAND, G., M.B., Ch.B. Edin. (Island of Lewis); McFARLAN, P. F., M.B. Edin., F.R.C.S. Edin. (Stirling District).

Vacancies.

For further information refer to the advertisement columns.

1berdeen Royal Mental Hospital.—Senior Asst. P. £400 to £500.
sethlem Royal Hospital, Lambeth-road, S.E.—Consulting Radiologist. £100 guineas.
irkenhead and Wirral Children's Hospital.—H.S. £100.
irkenhead Borough Hospital.—Hon. Radiologist.

Birmingham and Midland Ear and Throat Hospital.—Jun. H.S. £200.
Bradford Royal Eye and Ear Hospital.—Hon. Ophth. S.
Cambridge, Addenbrooke's Hospital.—H.P. £130.
Carmarthenshire Education Committee.—Chief Sch. M.O. £700.
Chelsea Hospital for Women, Arthur-street, S.W.—Registrar. £50. Also H.S. £120.
Chester, Burnthwood Sanatorium.—Res. Med. Supt. £900.
Dreadnought Hospital, Greenwich, S.E.—H.S. £150.
Dundee Royal Infirmary.—Asst. Radiologist.
Elizabeth Garrett Anderson Hospital, Euston-road.—H.P., Two H.S.'s, and Obstet. Asst. Each £50.
Folkestone, Royal Victoria Hospital.—Bacteriologist and Path. £50.
Gloucestershire Royal Infirmary.—Asst. S.
Hospital for Sick Children, Great Ormond-street, W.C.—H.S. £50
Hospital for Women, Soho-square, W.—Res. M.O. £100.
King's College Hospital Medical School, Denmark-hill, S.E.—Director of Dental Studies. £400.
Lancaster County Mental Hospital.—Asst. M.O. £590.
Leeds Education Committee.—Asst. Sch. M.O. £500.
Leeds Township Infirmary, Beckett-street.—Asst. M.O. £275.
Leeds University.—Lecturer in Bacteriology. £500.
Leeds, West Riding Asylum, Menston.—Fourth Asst. M.O. £400.
Liverpool, Brownlow Hill Institution.—Asst. Res. M.O. £300.
London County Mental Hospital Service.—Seventh Asst. M.O. £440.
London Lock Hospital, 283, Harrow-road, W.—H.S. £200.
Metropolitan Ear, Nose, and Throat Hospital, 2, Fitzroy-square, W.—Asst. S.
Midway Mission Hospital, Austin-street, Bethnal Green, E.—Sen. Res. M.O. £140. Also Jun. Res. M.O. £100.
Mount Vernon Hospital for Tuberculosis.—Surg.-Laryngologist.
Newcastle-upon-Tyne, Royal Victoria Infirmary.—Asst. Radiologist. £400.
Northamptonshire County Council Education Committee.—Asst. School M.O. £500.
North Ronaldshay, Orkney.—Med. Pract. £100.
Queen Mary's Hospital for the East End, E.—Cas. O. £150.
Rochester, St. Bartholomew's Hospital.—H.P. £200.
Royal Waterloo Hospital for Children and Women, Waterloo-road, S.E.—H.S. and H.P. Each £100.
Royal Westminster Hospital, King William-street, Strand, W.C.—Asst. S.
St. Lucia, Victoria Hospital.—Res. S. £500.
St. Marylebone General Dispensary, 30, Marylebone-lane, W.—Hon. P. Also Hon. S. to Ear, Nose, and Throat Dept.
St. Mary's Hospital for Women and Children, Plaistow, E.—Hon. P. and Hon. Asst. P.
Saint Pancras Dispensary, 39, Oakley-square, N.W.—Res. M.O. £225.
Salford Union Infirmary, Hope, Pendleton, near Manchester.—Second Asst. Res. M.O. £250.
Salop County Council.—Asst. M.O. £550.
Sheffield, Jessop Hospital for Women.—Asst. H.S. £100.
Sheffield Royal Infirmary.—H.S. for Ear, Nose, and Throat. £150.
South Shields County Borough Sanatorium.—Asst. Tub. O. £500.
Victoria Hospital for Children, Tite-street, Chelsea, S.W.—Sen. Res. M.O. £250.
Whitehaven and West Cumberland Infirmary.—Res. H.S. £225.
Winchester, Royal Hampshire County Hospital.—H.S. £150.
Windsor, King Edward VII. Hospital.—Sen. H.S. £200. Also Jun. H.S. £150.
Wolverhampton and Staffordshire General Hospital.—Res. Cas. S. £250.
Worcester General Infirmary.—Res. M.O. £200.

The Chief Inspector of Factories, Home Office, London, S.W., announces the following vacant appointments: Brentford and Ealing (Middlesex) and Sidmouth (Devon).

Births, Marriages, and Deaths.

BIRTHS.

DAVIES.—On May 8th, at Charlemont, Oakcroft-road, Blackheath, the wife of Dr. Arthur Davies, of a daughter.
DOUTHWAITE.—On May 10th, at Wigmore-street, W., the wife of Dr. A. H. Douthwaite, of a son.
MAYER.—On May 13th, at Thames Ditton, the wife of J. W. Mayer, M.C., L.D.S. Eng., of a daughter.
O'BRIEN.—On May 9th, at 16, Rothesay-terrace, Edinburgh, the wife of A. J. R. O'Brien, M.C., West African Medical Service, of a son.
SACKS.—On April 15th, at 13, New-road, E., the wife of Dr. Samuel Sacks (Muriel Elsie Landau, M.D. Lond., F.R.C.S. Eng.), of a son.

DEATHS.

COLLIER.—On May 10th, at Bonnie Brae, Hyde-road, Paignton, South Devon, Hopetoun Currie Collier, Brigade-Surgeon Lieut.-Colonel, aged 82 years.
KNIGHT.—On May 7th, at West Norfolk and King's Lynn Hospital, following an operation, Frederick Charles Rienzi Malins Knight, M.R.C.S., L.R.C.P., of Watlington, Norfolk (late of Claremont-square, London, N.).
STYLE.—On May 14th, at Queen-street, Mayfair, Mark Style, M.R.C.S., L.R.C.P., J.P., late of White House, Moreton-in-Marsh, aged 61.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETINGS OF SECTIONS.

Friday, May 25th.

STUDY OF DISEASE IN CHILDREN: at 5 P.M. (Cases at 4.30 P.M.)

Annual General Meeting:
Election of Officers and Council for 1923-24.
Discussion: on Birth Injuries.
Cases will be shown.

NEUROLOGY; ORTHOPÆDICS.

Members of these Sections are cordially invited to attend, and it is hoped they will coöperate by showing cases and joining in the Discussion.

EPIDEMIOLOGY AND STATE MEDICINE: at 8 P.M.

Annual General Meeting:
Election of Officers and Council for 1923-24.

Paper:

Prof. E. L. Collis: An Inquiry into the Mortality of Coal and Metalliferous Miners in England and Wales.

UNIVERSITY OF LONDON ADVANCED LECTURE IN PSYCHIATRY, in the Barnes Hall, Royal Society of Medicine, Wimpole-street.

THURSDAY, May 24th.—5.15 P.M., Prof. E. D. Wiersma (Groningen): The Psychology of Epilepsy.

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES, 11, Chandos-street, Cavendish-square, W.

FRIDAY, May 25th.—8.30 P.M., General Meeting. Sir Thomas Horder: Introductory address on Metastatic Gonorrhœa. Sir Wm. Willcox: Gonococcal Arthritis. To be followed by a discussion.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY, May 21st.—12 noon, Mr. Simmonds: Applied Anatomy. 2.30 P.M., Dr. Saunders: Medical Wards. 3 P.M., Mr. Simson: Diseases of Women.

TUESDAY.—10 A.M., Mr. Steadman: Dental Department. 12 noon, Dr. Burrell: Chest Cases. 2.30 P.M., Dr. Pritchard: Medical Wards.

WEDNESDAY.—10 A.M., Mr. Banks-Davis: Operations on Nose, Throat, and Ear. 2 P.M., Dr. Burnford: Medical Wards. 2.30 P.M., Mr. Donald Armour: Surgical Wards.

THURSDAY.—10 A.M., Dr. Grainger Stewart: Neurological Department. 2 P.M., Mr. MacDonald: Genito-Urinary Department. 2 P.M., Mr. Bishop Harman: Eye Department.

FRIDAY.—11 A.M., Mr. McDougal: Electrical Department. 2 P.M., Dr. Burrell: Medical Out-patients. 3 P.M., Mr. Sinclair: Surgical Out-patients.

SATURDAY.—9.30 A.M., Dr. Burnford: Bacterial Therapy. 10 A.M., Dr. Saunders: Medical Diseases of Children. 10 A.M., Mr. Banks-Davis: Operations on Throat, Nose, and Ear.

Daily, 10 A.M. to 6 P.M., Saturdays, 10 A.M. to 1 P.M., In-patients, Out-patients, Operations, Special Departments.

SOUTH-WEST LONDON POST-GRADUATE ASSOCIATION, St. James's Hospital, Ouseley-road, Balham, S.W.

FRIDAY, May 25th.—4.30 P.M., Dr. H. W. Barber: Demonstration of Dermatological Cases.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

Demonstration of Clinical Cases at 3.30 P.M.

MONDAY, May 21st.—Mr. J. Bright Banister: Gynaecological.

TUESDAY.—Mr. J. Metcalfe: Radiological.

WEDNESDAY.—Mr. C. H. Hayton: Throat and Nose.

THURSDAY.—Dr. Yealland: Medical.

FRIDAY.—Mr. E. Gillespie: Surgical.

NATIONAL HOSPITAL FOR DISEASES OF THE HEART, Westmoreland-street, Marylebone, W.

THURSDAY, May 24th.—5.30 P.M., Dr. J. Strickland Goodall: The Heart in Relation to Thyrotoxicosis.

INSTITUTE OF PATHOLOGY AND RESEARCH, St. Mary's Hospital, Paddington, W.

THURSDAY, May 24th.—4.30 P.M., Dr. Bernard Hart: The Development of Psycho-pathology as a Branch of Medicine.

LONDON SCHOOL OF MEDICINE FOR WOMEN, 8, Hunter-street, W.C.

TUESDAY, May 22nd.—5 P.M., Prof. A. L. McIlroy: Heart and Lung Complication in Pregnancy.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.

THURSDAY, May 24th.—4 P.M., Dr. Poynton: Prevention of Heart Disease in the Young.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C. 1.

POST-GRADUATE COURSE: MAY-JUNE, 1923.

CLINICAL LECTURES AND DEMONSTRATIONS.

TUESDAY, May 22nd.—2 P.M., Out-patient Clinic: Dr. Grainger Stewart. 3.30 P.M., Syphilitic Disease of Nervous System: Dr. Adie.

THURSDAY, May 24th.—2 P.M., Out-patient Clinic: Dr. Kinnier Wilson. 3.30 P.M., Focal Disease in the Medulla: Dr. Gordon Holmes.

FRIDAY, May 25th.—2 P.M., Out-patient Clinic: Dr. Gordon Holmes. 3.30 P.M., Vascular Disease in the Nervous System: Dr. Collier.

A COURSE OF 12 LECTURES ON THE ANATOMY AND PHYSIOLOGY OF THE NERVOUS SYSTEM will be given at 12 noon on TUESDAYS and FRIDAYS if there are sufficient entries for it.

Mr. Armour and Mr. Sargent operate at the Hospital on Tuesday and Friday mornings at 9 A.M., or at such other times as may be announced.

The fee for the whole Course is £12 12s., including Anatomy and Physiology, but these Lectures may be taken separately for a fee of £4 4s. The fee for the Course without Anatomy and Physiology Lectures is £10 10s. Special arrangements as to fees will be made for those unable to take the whole Course. Fees should be paid to the Secretary of the Hospital at the office on entering for the Course.

C. M. HINDS HOWELL, Dean of Medical School.

LONDON LOCK HOSPITAL, 91, Dean-street, W. 1.

TUESDAY, May 22nd.—2.30 P.M., Mr. J. E. R. McDonagh: Clinical Demonstration with Exhibition of Paintings.

THURSDAY.—2.30 P.M., Mr. W. Victor Corbett: Interpretations of the Wassermann Reaction. 4.30 P.M., Mr. Lawrence Abel: Some Complications of Gonorrhœa in the Male.

FRIDAY.—4 P.M., Mr. Johnston Abraham: Syphilis in Women.

At 283, Harrow-road, W. 9.

WEDNESDAY, May 23rd.—3 P.M., Mr. Ernest Lane: Treatment of Syphilis by Trepol, the Arsenical Compounds, and Intravenous Cyanide of Mercury.

LONDON HOSPITAL MEDICAL COLLEGE, Mile End, E.

TUESDAY, May 22nd.—5.15 P.M., Dr. Millais Culpin: Symptomatology (2).

WEDNESDAY.—4.15 P.M., Dr. W. M. Feldman: Embryonic Physiology.

FRIDAY.—4.15 P.M., Mr. Russell Howard: (Lecture on Surgery) The Testicle. 5.15 P.M., Dr. Millais Culpin: Diagnosis.

INFANTS HOSPITAL, Vincent-square, S.W. 1.

WEDNESDAY, May 23rd.—8.45 P.M., Dr. Helen Mackay: The Treatment of Nutritional Disorders of Infancy.

THURSDAY.—6 P.M., Dr. Eric Pritchard: The Physiology and Pathology of Nutritional Disorders.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone-road, N.W.

THURSDAY, May 24th.—5 P.M., Mr. A. W. Bourne: Puerperal Pyrexia.

SALFORD ROYAL HOSPITAL.

THURSDAY, May 24th.—4.30 P.M., Mr. Ollerenshaw: Demonstration of Orthopaedic Cases in the Wards.

UNIVERSITY OF BRISTOL POST-GRADUATE DEMONSTRATIONS (in the Medical Theatre).

THURSDAY, May 24th.—3.30 P.M., Dr. J. R. Charles: Hysteria, Signs, Differential Diagnosis, Treatment.

THE LANCET: SUBSCRIPTION RATES.

Notes, Comments, and Abstracts.

THE EVOLUTION OF THE MODERN TREATMENT OF SEPTIC PERITONITIS.¹

By H. W. CARSON, F.R.C.S. ENG.,

SENIOR SURGEON, PRINCE OF WALES'S GENERAL HOSPITAL.

It may seem curious that I should have chosen the history of peritonitis to honour a man who was not much interested in the study of the past and in whose day peritonitis was little understood. But John Hunter's views on peritonitis, like his views on so many things, were ahead of his time. He says: "That the inflammation of the peritoneum rises from the stimulus of imperfection is also evident, because if a man is wounded in the belly with a sword, which has also wounded one of the intestines, if the wound in the abdomen is closed and unites by first intention, the wound in the intestine will unite with some parts with which it comes in contact, either by extravasated blood or the adhesive inflammation, and no further trouble will ensue, because the stimulus of imperfection has not been given. But if a man is wounded in the belly and there is no wound of the viscera, yet if the wound is kept from healing by first intention, the whole peritoneum becomes inflamed immediately—not from the spreading of inflammation by the continuity of surface, but the consciousness of imperfection in the membrane itself by which the whole is brought into the same action."

And again he says: "The inflammation may be a true inflammation or the erysipelas. At first the apparent indication would be bleeding and that largely; but if it is of the erysipelas kind, we may be led by these symptoms beyond the quantity suitable to the constitution; yet I do not know what we can do better. I should be inclined to reduce the patient to the lowest pitch rather than allow suppuration to take place, for that would certainly kill. *How far in such cases it might appear desirable to make an opening into the abdomen and throw in warm water repeatedly to wash away the matter, I will not undertake at present to determine.*"

He also recognised puerperal fever as a true peritonitis, a conclusion that preceded the work of Bichat by some 30 years.

The "Iliac Passion."

There is little direct evidence to be obtained from pre-historic sources. The ancient Egyptians, as you know, deposited the internal organs of the dead in four canopic jars, but Prof. Elliot Smith and Prof. Wood Jones in their "Archæological Survey of Nubia" could only report one case of adhesions due to old peritonitis, and that not even in a jar, but in the pelvis of a woman buried in the cemetery No. 2 on Hesa. There is nothing in the Ebers papyrus (1500 B.C.) on acute abdominal disorders, but in the fragmentary tablets of the library of Assur-Bani-Pal, at Nineveh (600 B.C.), there are instructions for treating colic. It is certain that abdominal disorders were well known in Egypt, for Herodotus states that medicine was practised upon a plan of separation—thus "Some cure diseases of the eye, others of the head, others again of the teeth, others of the intestines." There is in the Wellcome Museum an excellent specimen of a clay votive offering found on the banks of the Tiber by Mr. Thomson, who very kindly demonstrated it to me. It looks exactly like the post-mortem appearances of the abdominal cavity of a patient dead of diffuse peritonitis and is life size. Mr. Thomson dates it about A.D. 200.

It can be well understood that in early mediæval times, when there were no post-mortems and symptoms were more important than signs, a good deal of mystery attached to any sudden, severe, painful, and fatal illness, such as is seen in peritonitis, obstruction, appendicitis, or perforation; and when the victim was a personage of importance all sorts of whispers of foul play would be current. William the Conqueror possibly died of peritonitis following a rupture of the intestine; Henry I. had a mysterious abdominal seizure, which is generally believed to be ptomaine poisoning; John died after an unwise meal of peaches. Stephen's death seems to have been due to what was then known as the "iliac passion." What exactly was comprehended under the name of "passio iliaca" is unknown; but it seems to approach nearly to the dreadful modernism—"the acute abdomen," and to include peritonitis, intestinal obstruction, and even strangulated hernia. It was also known as "ileus" and "miserere." John of Gaddesden in the Rosa Anglica, 1314, differentiates between the iliac passion, which is probably peritonitis,

the colic passion, which may be intestinal obstruction, and the renal passion, and speaks of the iliac passion as being accompanied by frequent vomiting, by hardness of the belly, and by extremely acute pain, as if a gimlet were boring through the intestine. Fomentations and enemata were the chief means of treatment. Praxagoras of Cos, 100 B.C., bravely treated the vomiting by giving emetics until fæculent vomiting occurred.

Little advance was made until the seventeenth century, when Thomas Willis (1621-75) described puerperal fever, and in an account of the colic passion disagreed with the theory advanced about that time, that it was to be counted among the distempers of the brain and nervous stock. He says: "The intestines enter into pains and torments, being irritated by wind, medicines, cholera and perhaps other humours contained within their cavities; but if it were so, those things which loosen the belly should give certain ease, the contrary of which often happens—to wit by some more violent or often purging, when the disease has grown worse." It is interesting to find this great truth, of which we have only recently been convinced, being enunciated 250 years ago.

Early in the eighteenth century Haguenaal gave a very interesting account of peristalsis and antiperistalsis in the iliac passion. In 1759, Heister reported the first case of appendix abscess, which he discovered in 1711, when doing a post-mortem on a malefactor, in the public theatre of Altdorf.

This was followed in 1759 by the historic case of Mestivier, who reported a case of appendicitis occurring in a man of 45, who came to the Hôpital St. André de Bordeaux with a large abscess in the right iliac fossa. One pint of offensive pus was removed by incision and on post-mortem a pin was found in the appendix. A few other cases were reported in France about this time, and in 1812 Parkinson, a pupil of John Hunter, reported the first case in England. The last mention of the iliac passion as such was made by Sydenham in 1788. He describes two forms—the obstructive and the irritative—and says that the true iliac passion is the second. He says the method of curing it had hitherto remained a secret, "notwithstanding the pretension of such as had recourse to quicksilver and leaden bullets, which do little service and are frequently very dangerous." He recommends that the salts of wormwood with a spoonful of lemon-juice be taken morning and night and that in the intervals some spoonfuls of mint water by itself should be given twice every hour. "At the same time, I order a live puppy to be applied to the belly until the purgative is given two or three days afterwards." This period is closed by Erasmus Darwin in his Zoonomia, 1796, under the heading of "inverientia." He says: "If the vomiting continues after the pain ceases, and especially if the bowels become tumid with air, which sounds on being struck with the finger, these patients seldom recover."

Puerperal Fever.

As regards the generally accepted treatment for peritonitis at the beginning of the nineteenth century, Benjamin Travers and Thomas Sutton, writing in 1812 and 1813 respectively, considered that the treatment consisted in absolute rest, purgatives—especially magnesium sulphate—abstinence from food, cold applied to the abdomen, blood-letting in acute cases, and opium only occasionally and very sparingly. Of puerperal fever, Dr. Sutton said: "I have never had the happiness to discover anything in the shape of a remedy for this cruel disorder excepting copious blood-letting."

A great deal of attention now began to be given to puerperal fever. John Hunter tells the story of "a man whom I tapped at the hospital and died on the third day. I said he died of puerperal fever. This was smiled at in the hospital and some were pleasant in remarking on the curiosity of a man being delivered; but a few months afterwards, another having the same fate, I convinced them by dissection that he had died of suppuration of the peritoneum, which we must admit to happen in puerperal fever." The greatest advance was made by John Hunter's friend and fellow student, Charles White of Manchester, 1728-1813, who wrote his first treatise in 1773 on "The Management of Pregnant and Lying-in Women," nearly 90 years before Semmelweis, to whom so much credit has been given. White held that puerperal fever was a putrid fever, dependent on retained lochia and dirty surroundings. He advised the sitting up of the patient after delivery, getting up on the second or third day, and antiseptic injections into the uterus if the lochia became acrid or putrid. He says that as the puerperal fever does not appear till after delivery, so neither does absorption of matter from an abscess till it be opened and the air have access. "We may, I think, conclude that the absorption of matter is the immediate cause of the puerperal fever, as well as that consequent upon abscesses and ulcers." White was a great believer in fresh air and gave minute instructions as to the ventilation

¹ Abstract of the annual oration of the Hunterian Society, delivered on March 19th, 1923.

of the wards. He washed his hands in chloride of lime solution, fumed the apartment with brimstone after a patient had had the disease, cleaned the floor and woodwork with vinegar, and had all the linen and curtains washed. His principles were adopted by Robert Collins, Master of the Rotunda Hospital, Dublin, 1826-33, who, finding puerperal fever rampant, adopted in 1829 a very drastic method of cleansing the wards, filling them with chlorine gas, and covering floors and woodwork with chloride of lime cream. He stoved the bed-linen at 120-130° F., and during four years did not lose a single case from puerperal fever.

Peritonitis as an Entity.

In 1802 Bichat, a young surgeon in the French Revolution, did his great work on peritonitis, and he was soon followed by Laennec. They both insisted that peritonitis was an entity, in contradistinction to the generally accepted view that all abdominal inflammations were infections of various organs, such as gastritis and enteritis, and this was further developed by Bichat's pupil, Gasc.

Attention now began to be paid to the possibility of operating for appendicitis, but progress was stopped by the result of an unfortunate case. In 1827 a French medical man, Melier by name, diagnosed a case as an abscess due to a recurrent appendicitis. He called in Dupuytren to operate. Dupuytren, although not enthusiastic, agreed to do so, and opened the abscess; a sinus resulted, and some months afterwards the patient died from the bursting of a residual pelvic abscess into the peritoneal cavity. This confirmed Dupuytren in his opinion that operation should not be done on those cases; he was the leading surgeon in France, his opinion was always quoted, and the progress of operation for appendicitis was put back—in France at any rate, and also, I think, in England—about 30 years. Dupuytren discusses on several occasions the reasons why swellings occur in the right iliac fossa rather than in the left, and concludes "that the cæcum offers at its point of union with the small intestine a narrowing, so marked, that at this place, the ileo-cæcal valve, one often sees collect many foreign bodies, which could themselves cause this abscess. The left side is quite different and does not show any narrowing. On the right side the feculent material had to circulate against the law of gravity." This view was generally adopted, so that typhlitis and typhlo-enteritis were more often spoken of than appendicitis. Husson and Dance, colleagues of Dupuytren at the Hôtel Dieu in Paris, and Ferrall, in Edinburgh, held this view very strongly; but Dr. John Burne, of the Westminster Hospital, in a paper read before the Medico-Chirurgical Society in 1836, reports several cases of appendicitis proved at post mortem, and suggests that an incision should be made "when a lump, emphysematous in character, approaches the surface." He draws a very definite distinction between typhlo-enteritis and perforative ulceration of the appendix based on their symptomatology, typhlo-enteritis being cured by aperients, while the symptoms persist if the appendix is at fault. He considers that there are four causes for inflammatory tumours in the right iliac fossa, placing them in the following order of frequency: (1) typhlo-enteritis; (2) perforative ulceration of the cæcum from within, with abscess behind the peritoneum (comparatively rare); (3) perforative ulceration of the cæcum from without, with abscess behind the peritoneum (comparatively rare); (4) inflammation of the appendix (very rare—only one case had come under his notice).

Dr. James Copland, of the Orkney Islands, in his "Dictionary of Practical Medicine" (1844), considered appendicitis more dangerous than typhlitis and is strongly opposed to aperients, "as they cause ileus to follow." Grabowski, of Poland, in 1836, called attention to the occurrence of a quiescent period in acute peritonitis, but he does not recommend operation. However, ten years later Jobert and Guérin recommended opening the abdomen and washing out the peritoneal cavity with water at blood heat until it returns clear. By this time (1846) anaesthesia was introduced and this gave a tremendous impetus to surgery. Not only were the ordinary operations now done easily and methodically, but it became possible to do many operations, and among them some abdominal operations, which were formerly not even contemplated. But antisepsis and asepsis were not yet—or no longer—practised. Surgeons operated in dirty coats with dirty hands; the instruments were not clean; sponges were dreadful; the sanitary conditions of the hospitals were beyond description, and the mortality was frightful. In the midst of this saturnalia, Syme, of Edinburgh, made personal cleanliness a cult. Without knowledge of bacteriology, for Pasteur had yet to reveal his secret; without any knowledge of antiseptics, for his brilliant son-in-law, Lister, was yet to do his work (Lister's first article on antiseptics was published in THE LANCET in 1867²), he achieved by simple cleanliness results which were for that period amazing. Unfortunately Syme took up a strong stand against abdominal surgery.

² THE LANCET, 1867, i., 326.

To illustrate the casual manner of the surgeon of that time, a story is told of Sir Astley Cooper, who removed a wen from the scalp of King George IV. On going to see his illustrious patient next morning, very nervous as to the result of the operation, he was rather coldly received. When he got home, he inquired of his nephew why this should be. The nephew pointed to the fact that his cravat, shirt, and hands were bespattered with blood. "God bless me, but I was not aware of it," said Cooper, "and the King, Sir, is so very particular!"

A very illuminating medical view on intestinal obstruction is seen in the lecture by Dr. Brinton, physician to the Royal Free Hospital, delivered in 1859. He says: "Our wonder at the happy audacity of the operator is unaccompanied by any wish or hope of imitating his procedure. That the operation may succeed, there is scarcely any need of these cases to inform us; that it is justifiable is a conclusion which, even supposing them to record failures and successes with rigid impartiality, they would be utterly incapable of establishing. The question 'Is gastrotomy justifiable in intestinal obstruction?' must be answered with a decided negative. In intussusception an operation ought not to be mooted." He goes on to make the amazing statement that 30-40 per cent. of all intussusceptions recover by casting off the intussuscepted part. He says that operation should be confined to obstruction by bands and twists and should always be preceded by medical treatment, which may cure.

Lister.

In February, 1860, Lister obtained an appointment at Glasgow and had full charge of wards in the infirmary in 1861. He had done much work by that time on inflammation, and introduced into his practice in Glasgow the most scrupulous cleanliness, really an elaboration of Syme's methods; but the secret eluded him, until he read in the early part of 1865 Pasteur's papers on putrefaction, which had appeared in the "Comptes Rendus Hebdomadaires" during 1863. In March, 1865, he made his first antiseptic treatment with crude carbolic acid in a case of compound fracture of the leg. The patient, a poor surgical risk, died. His second case, a healthy boy of 11, whose leg was crushed by a cart-wheel, was successful. Soon after, in 1869, Lister left Glasgow to succeed Syme in Edinburgh and was able to say that he had had "three years of immunity from the ordinary evils of surgical hospitals" in spite of great sanitary disadvantages.

But now a determined effort was made to improve hospital treatment, and Sir James Young Simpson, in 1869, published statistics of the results of amputation. Of 2089 results of hospital amputation 40 per cent. died; of 2098 country amputations, 11 per cent. died. This paper made a great stir, and a meeting was held at Leeds to consider these statistics, with the result that the hospitals were vindicated.

Abdominal Operation in the Second Half of the Nineteenth Century.

Now, how do matters stand with regard to peritonitis? We have seen the period initiated by Bichat, when peritonitis was recognised as an entity. In a second period, 1825-43, the causes of peritonitis were studied, particularly tuberculous peritonitis and puerperal fever. In the third period, 1850-80, partial peritonitis was discussed; as, for instance, pelvic peritonitis by Bernutz and subphrenic abscess by Foix. The fourth period was concerned with bacteriology. It is interesting to see what the hospitals were doing in abdominal work during this period. I had before me the Guy's Hospital Reports for the seven years 1854-60, edited by Dr. Fagge. During that time 54 abdominal operations were done and 33 died; 44 of these operations were ovariectomies, of which 23 died. Twenty years later, at St. Bartholomew's Hospital in the six years 1874-79, abdominal operations were confined to colostomies and ovariectomies. Of the 11 colostomies 9 died; of the 26 ovariectomies 11 died. At this time a separate record was made of all cases of pyæmia admitted to or arising during treatment at the hospital.

We now read for the first time accounts of peritonitis occurring after an abdominal operation. In 1867 Koeberlé, the Alsatian surgeon, who introduced hysterectomy, advised that if a fluid extravasation followed an inflammatory process in the peritoneum, it is necessary to open the peritoneal cavity without delay. He records a successful case after ovariectomy and he thought the fluid harmful because of the neighbouring fecal matter in the intestine. Netter advanced his "coryza" theory, saying that the first fluid secreted in peritonitis was entirely irritant, and compared it to the fluid in coryza, which causes erosions of the nostrils and lips. He advised irrigation and made the ingenious suggestion that if the exudation is abundant, it is more dilute and less irritating, and the prognosis therefore better. Both Burdon-Sanderson, in 1876, and Mosiman, in

1881, produced peritonitis experimentally in animals by injections of various substances. Then followed a host of writers on the bacteriology of peritonitis. Pasteur discovered streptococci in puerperal fever in 1878-79. Metchnikoff, in 1884, described phagocytosis; Leyden, in 1884, and Winkel, in 1886, proved that the micro-organism in puerperal fever and erysipelas was the same. In 1885 Cornil and Babès described an organism found in perforative peritonitis, causing gas and derived from the intestine. This was named by Escherich in 1886 the *Bacillus coli communis*. Tavel and Lanz, in their much quoted account of the bacteriology of peritonitis (1893), described many different varieties. They dealt chiefly with appendicitis, and though they realised that the *Bacillus coli communis* was often present, they took the view that an anaerobic organism played the most important part.

Operative treatment, however, did not advance very rapidly and we find Mickulicz, Billroth's assistant, in 1886, saying in speaking of laparotomy: "It has not yet the favour of the medical public accustomed to employ only medical means; but it has been followed by results so marvellous in the most desperate cases, that one must consider it as the treatment of the future in peritonitis." In 1886 Lawson Tait, lecturing on the results of 139 consecutive ovariectomies without a death, says: "This success has absolutely destroyed our fear of the peritoneum and has justified our opening that sacred sac very much as we open our pockets." He introduced his technique in 1875, filling the abdomen with blood-warm water and washing all organs, repeating till the water comes off clear. "The water has not been boiled and contains no drug or chemical substance. The water is plain, unfiltered tap water, warmed by the addition of enough from the boiler. All opiates are forbidden in my practice, unless they are required to ease a dying patient out of the world."

"I have never said," remarked Lawson Tait in 1892, "that the purgative treatment will cure peritonitis; for peritonitis, once it is completely established, is practically an incurable disease and almost always uniformly fatal—but when it is completely established I do not know." Lawson Tait did 4000 abdominal sections and undoubtedly proved that the abdomen could be opened safely. He followed a system of crude asepsis and would have nothing to do with Lister and his methods.

In 1888 Mr. J. D. Malcolm described for the first time the condition now known as pseudo-ileus. Speaking before the Pathological Society on "Sequelæ of Laparotomy," he says: "In all cases the nervous plexuses of the intestine are more or less affected, their activity being first increased and afterwards paralysed in proportion to the severity and duration of the stimulus. The paralysed condition usually passes off in a few hours, but there is evidence that the bowel is distinctly wanting in power for from four to six days after operation." This was a great discovery and paved the way for further investigation and treatment of the condition, which still causes anxiety and the treatment of which is still a matter for debate.

The next important pronouncement came from Sir Frederick Treves in 1894, in his Lettsomian lectures on peritonitis. He mentioned that the chief organism was *B. coli communis*, while *Streptococcus pyogenes* was the common cause of post-operative peritonitis. His treatment consisted at that time of rest in the recumbent position, very little fluid by mouth, and warm water by rectum rather than nutrient enemata. If peritonitis is established, aperients are of no value; but he differentiates between this condition and perityphlitis, in which aperients are very valuable, very much like Dr. Burne in 1836. He was also in favour of blood-letting, which, he says, may with advantage be more extensively employed. His operative measures consisted of opening localised abscesses, and drainage without irrigation; in generalised peritonitis irrigation should be employed, using normal saline solution, if dry sponging is not successful in cleansing the cavity. In perforation cases he did not advise a long search for the cause, and considered that if the operator can rid the serous cavity of the effects of the perforation he may very often leave the breach itself to be dealt with by natural means. In these cases he dusted the serous membrane liberally with iodoform, except in children, and did not drain except by strips of gauze passed among the coils of the intestine. He did not drain the pelvis, but passed a rubber tube "into the midst of the area which is most disturbed." As for the use of morphia, he says: "Morphia should never become a feature in the routine cure of peritonitis. It masks the symptoms, hinders the natural process of cure, and hampers treatment." I think this view fairly represents the treatment of peritonitis 30 years ago.

The Twentieth Century.

Perhaps the most important work on the bacteriology of peritonitis was published in 1905 by Dudgeon and Sargent. After going very thoroughly into the types of bacteria

commonly found, they discuss very briefly points in technique and treatment, such as flushing the abdomen and drainage, and particularly do they advise against the use of morphia, which they say "superadded to the toxic paresis of the bowel may just turn the balance against recovery." They held that the post-operative pyrexia in ruptured tubal pregnancy was due to *Staphylococcus albus* and not to any hypothetical toxic substance produced by coagulation of blood; that the colon bacillus is the most important, the most common, and not infrequently the most virulent of the organisms which are known to cause peritonitis. At the same time they proved that the *Staphylococcus albus* had a protective function in causing phagocytosis.

In 1895 Moscatello, of Turin, had made the important discovery that absorption from the peritoneal cavity took place especially through the diaphragmatic peritoneum and that there was a lymph flow towards the diaphragm independent of gravity. This was the foundation for the great work done by J. B. Murphy in the treatment of peritonitis. It is not perhaps too much to say that his announcement at the British Medical Association meeting in Toronto in 1906 revolutionised the whole treatment of peritonitis. He recommended the sitting-up position, the administration of saline by the continuous drip method into the rectum, combined with drainage of the peritoneal cavity and the administration of aperients. I had the good fortune to hear this lecture; on returning to London I at once put his technique into operation, with the result that my death-rate in diffuse peritonitis fell 20 per cent. forthwith. Thousands of lives must have been saved by this device alone and general peritonitis lost half its terrors.

I will not weary you by referring to the many investigations which have taken place since that time. It is perhaps enough to draw your attention to the work on the causes of death in intestinal obstruction, to the bacteriological examination of the exudate as a means of prognosis, and to the rival method to Murphy's method of treating peritonitis, which one might call the "passive" as distinguished from the "active" method. About 12 months ago I addressed an inquiry to all the principal hospitals in Great Britain, asking for an account of the method adopted in the treatment of peritonitis. It was clear from the replies I received that on such questions as active or passive treatment opinion is widely divided. But all are agreed in condemning irrigation, and there is an increasing tide of opinion in favour of immediate closure of the peritoneal cavity instead of drainage.

We are still almost too close to the great advances of the last few years to estimate their value. I was myself house surgeon to Hooper May, one of Syme's dressers, and when I first entered the wards of St. Bartholomew's Hospital little abdominal surgery was done. In 1890 only 27 abdominal sections were performed, 9 of which were colostomies, and of the 27, 18 died. In 1891 51 laparotomies were done, of which 25 were colostomies, and of these 51, 19 died. I believe the first gastro-enterostomy was done there in that year, and also a cholecystotomy—both without success. We irreverent students used to speak of emergency laparotomies as the coup de grâce. I have performed hysterectomy with the serre-neud and have washed out many an abdomen with antiseptic lotions. But these are vain regrets!

There is still much to be done, for though we now feel confident that peritonitis will not follow a clean laparotomy, our mortality is still too high in septic peritonitis, but we are ever hoping that with increased knowledge will come the demand for earlier treatment, in which alone safety lies.

COLOUR AND SEXUALITY.

THE connexion, says Scheuer,¹ between coloration and sexual selection was established by the Darwinian school, and the same holds good even as regards man himself. Sudermann has remarked that from the bird of paradise and the peacock, up to the Hussar lieutenant, we see the eternal masculine arrayed in the brightest colours. The attraction of military and other uniforms for women is universal, and male inverters as a class resemble them in this respect. There is a tendency for military uniform to be the brighter, the higher the rank of the wearer. This is so even in the inconspicuous garb of the modern service uniform, since red tabs distinguish a staff officer. Technically speaking, women have a certain "uniform fetishism"; and just as fetishism is closely bound up with anti-fetichism, so cases have been known of the brides of soldiers and sailors taking an aversion to their husbands when these came home from active service and appeared in civilian clothes. Feminine fondness of the gaudy colours of the uniform is really a primitive trait, for in primitive peoples it is the male, not as with us the female, that is the more adorned. Savage men, says Westermarck, paint and tattoo themselves largely as a sexual attraction, beginning at the

¹ O. F. Scheuer: Zeitschrift für Sexualwissenschaft, April, 1923.

age of puberty, and treating especially those parts of the body which are exposed to view. Waitz records the answer of some uncivilised men to a question why they tattooed themselves—"For the same reason that you dress yourself, to attract the women." Civilisation has here reversed the rôles of the sexes, because with civilisation marriage becomes difficult for women. The author thinks Sudermann correct in his contention that, face to face with the risk of dying an old maid, civilised woman adopts the sexual lure of adornment, especially the adornment of colour. This phenomenon is seen most plainly in the prostitute, that product of civilisation, with her rouge and dye and powder. In warm climates artificial colouring may be applied to other parts of the body than the head and face; the Creole women of Caracas, for instance, rouge their bosoms, whilst in the East the nails of both fingers and toes are stained red with henna. It is said that some modern civilised women have had sound teeth filled with gold, merely in order to increase their attractiveness. Another instance of the association of colour with sexuality is the admiration of white races for whiteness of female complexion. Heine's poems are full of allusions to "lily-white fingers," or a small white hand, or snow-white shoulders. This is probably because the female in fair races is even less pigmented than the male. However, there is a certain attraction by contrast too. The blonde Schopenhauer, according to his own account, attracted brunettes. For this reason women easily fall in love with foreigners, even those of lower race, or those who are their conventional enemies—e.g., war prisoners or troops of occupation.

COLONIAL HEALTH REPORTS.

St. Lucia.

According to the census taken in April, 1921, the population of St. Lucia consisted of 51,505 persons—23,506 males and 27,999 females. These figures, compared with those of the census of 1911, show an increase of nearly 6 per cent. for the decennial period. There were 93 Europeans, of whom 52 were born in the United Kingdom. The birth-rate and the death-rate in 1921 were respectively 37.2 and 21.8 per 1000 of the total population. The principal hospital of the colony—the Victoria—is located within half a mile of Castries; the staff consists of a resident surgeon in charge, with a European nurse matron, assisted by a good class of native nurses. The number of patients admitted during 1921 was 1575, of whom 1006 were discharged cured and 133 relieved, while 111 died; 327 surgical operations were performed. Owing to the low salaries provided, difficulty has been experienced in obtaining the services of qualified men to fill vacancies on the medical staff of the colony. It is recognised that when the colony's finances will permit the emoluments of the medical officers must be increased. The International Health Commission continued their operations during the year over a considerable area. If effective sanitation can be maintained this philanthropic campaign should prove a lasting benefit to the health of the labouring classes. The climate of St. Lucia is healthy and compares favourably with other West Indian colonies. Not for many years has there been any outbreak of small-pox or yellow fever, or other quarantinable disease or serious epidemic. The temperature ranges from 70° F. in the cool season to 90° in the summer. The town of Castries, lying on low land, with the majority of the houses roofed with corrugated iron, is sometimes hot during the day, but is cool at night. On the hillsides around, where many of the best residences are built, it is never unbearably warm, while on Morne Fortuné, where the garrison was formerly located, the temperature in the winter months falls as low as 60°, and the climate at all times during the year is extremely mild and pleasant for Europeans. The rainfall in 1921 was 90.06 inches. Much has been written about the presence of the dreaded fer-de-lance snake in St. Lucia. In former years the colony was infested with this dreaded reptile. In 1870, Sir G. Des Vœux, the then administrator, offered a reward of 6*d.* a head, which resulted in the destruction in one year of 52,000, at a cost to the colony of £1300. As the result of the introduction of the mongoose in 1890, and with the advance of cultivation and the continuation of rewards, the remnants of this pest have been driven into the interior.

Ashanti.

There was no serious epidemic in Ashanti during 1921, and the health of the native population seems to have been normal. At Coomassie Hospital, which is the finest native hospital on the Gold Coast, there were 1125 admissions and 83 deaths. The prevalent diseases were ulcers, malaria, and venereal, and there was also a considerable number of pulmonary and bronchial affections. For Europeans the year was a bad one. There were 172 admissions to the hospital as against 149 in 1920, and 186 officials on the sick list, as compared with 116 in the previous year. There were six cases of blackwater fever, with two deaths, as against three cases with one death in 1920. The European population of Coomassie is about 225 out of a total of 20,000. The

census of Ashanti, taken in April, recorded a population of 407,000, an increase of 119,230, as compared with ten years ago. It is not possible to speak of the accuracy of the census with any great confidence, and the increase in the population is not necessarily a natural one. It may be due to a more extensive acquaintance with the country and to less suspicion on the part of the inhabitants.

A BOOK FOR PROSPECTIVE MOTHERS.

THE fact that the difficulties and dangers associated with pregnancy and childbirth are largely preventable is slowly becoming better known among the population as a whole. Even yet, however, there are only too many women who neglect to take the necessary care to safeguard themselves from harm during their labours by placing themselves under medical care during the period of their pregnancy. Until this becomes universal childbirth will still take its toll of life and accidents will still happen which a little care and forethought could readily have foreseen and prevented. It is difficult to persuade the young woman that there is a definite danger in childbirth and often even more difficult to make her husband realise that parturition is not always in modern times the simple physiological act it should be. A little book¹ has reached us in which all the necessary facts are set forth in clear and simple language and in which all that is required to be known, not only by the mother but also by the maternity nurse, is included. The failure to spread knowledge among expectant mothers, more especially among the poorer classes and in country districts, showing that there are certain dangers which may be readily recognised and avoided, is accountable for some at least of the heavy death-rate which even at the present day accompanies the act of parturition.

A little volume of this type should be useful to those who are engaged in health visiting as well as to women expecting a child. Miss Van Blarcom is to be congratulated on her book, which should find a large number of appreciative readers.

A DIRECTORY OF TUBERCULOSIS INSTITUTIONS.

A LIST, dated April, 1923, has been issued by the Ministry of Health (to supersede the list of May, 1921) containing all names of sanatoriums and other residential institutions for the treatment of persons suffering from tuberculosis and resident in England and Wales, with the names of administrative counties and county boroughs in which the institutions are situate, and the date on which the approval expires in each case. Distinguishing marks are placed against names of institutions where treatment may include a course of training, where Government training sections have been provided for ex-Service men, and where admission is restricted as regards class of diseases and sex of patients.

WORK OF THE RED CROSS IN CANADA.

THERE are many districts in Canada in which medical and nursing services are totally lacking, and a statement occurring in the "Handbook of Child Welfare Work in Canada," edited by Dr. Helen MacMurchy (Dept. of Health, Ottawa, 1923), to the effect that settlers in outlying districts often suffer untold hardships for lack of skilled attention, is one that can be readily believed. "Imagine," she says, "the hardship of acute pneumonia, or appendicitis, or brain fever, or one of the accidents which are liable to accompany the arrival of the baby, or a fractured skull, arm, or leg, a gunshot wound, or an artery bleeding from an axe wound, and no doctor or nurse within 20 or even 50 miles!" The Red Cross has come effectually to the rescue, and there are now 18 Red Cross hospitals and nursing stations in the three Prairie Provinces. The hospitals have from four to twelve beds each, but the nursing stations have only an emergency ward room which is not used except in extremity, the nurse's work consisting in visiting any injured or sick people in her territory known to her or to whom she may be summoned. In Manitoba the Red Cross also supplies a full-time medical practitioner, who spends all his time in regular visits to the various stations, much of his work being of a preventive character.

Red Cross nurseries have been established at the ports of St. John, Halifax, and Quebec to welcome immigrant women and children on their arrival in the country. Beds, cots, cooking and bathing facilities are provided, and suitable food is offered to both mothers and children. Any infant or child discovered by the nursing staff to be suffering from a condition requiring medical investigation or treatment is reported to the Red Cross headquarters, arrangements being made for all such children to be visited by a public health nurse. During the year more than 9500 children were cared for in the nurseries at these three ports. The Junior Red Cross also exerts a powerful influence in Canada, some 72,700 children having already enrolled as members.

¹ Getting Ready to be a Mother. By Carolyn Conant van Blarcom, R.N., Author of Obstetrical Nursing; The Midwife in England. London: Macmillan and Co. 1923. Pp. 237. 6*s.*

An Address

ON THE PRESENT POSITION OF DIABETES AND GLYCOSURIA, WITH OBSERVATIONS ON THE NEW INSULIN TREATMENT.

*Delivered at the Congress of Public Health, Scarborough,
on May 18th, 1923.*

By HUGH MACLEAN, M.D. ABERD., D.Sc. LOND.,
M.R.C.P. LOND.,

PROFESSOR OF MEDICINE, UNIVERSITY OF LONDON
(ST. THOMAS'S HOSPITAL).

SINCE the classical observation of Thomas Willis in 1675 that the urine in diabetes contained sugar, no disease, perhaps, has been the object of so much combined clinical and laboratory investigation. Despite all this, we are to-day almost entirely ignorant of the nature of the fundamental defects in metabolism which give rise to diabetes, and it is fairly safe to prophesy that the mystery will remain unsolved until the secrets of general metabolism are fully unravelled. We are still very far from this enviable position, and our present knowledge of diabetes resembles a mechanical puzzle in which only a few of the pieces have been placed in their proper positions. Within recent years, however, our clinical conception of diabetes has been placed on a more secure foundation, for we are now able, in the great majority of cases, to say definitely whether or not a patient suffering from glycosuria is also suffering from diabetes. That this is an important fact will be recognised by all who have been called upon to decide whether or not a patient with glycosuria was really diabetic. A celebrated London physician, in discussing this question with me some time ago, made the following remark:—

"I have been watching patients with glycosuria for more than 25 years. Many of these patients whom I thought, when I first saw them many years ago, to be suffering from early diabetes, are still alive and as fit as, or more fit than I am. Others, whose condition I looked on as probably of little importance, are long since dead of diabetic coma."

This, I think, sums up the position admirably, and must appeal to all of us who have had any experience in dealing with this disease.

NEWER METHODS IN INVESTIGATING GLYCOSURIA.

When a patient who happens to be suffering from glycosuria consults his doctor it is not an unusual experience for the glycosuria to be discovered more or less accidentally in the course of routine examination. If such a patient feels somewhat run down and out of sorts, and physical examination results only in negative findings, there is a very great temptation immediately to ascribe the patient's condition to diabetes. In many such cases experience shows that the glycosuria is purely accidental, and has nothing whatever to do with diabetes. From the patient's point of view it is most important to ascertain the nature of the glycosuria, for patients are not infrequently submitted to severe antidiabetic treatment when the condition is only a simple renal glycosuria. An instance of this kind came under my notice a few weeks ago, when a patient was admitted to my wards suffering from what was said to be severe diabetes. His history and certain of his symptoms were exactly what might be expected in this disease, and his urine contained both sugar and acetone. Naturally, before admission, he had to run the gauntlet of several medical men, yet on investigation he proved to be quite free from diabetes, and was as capable of utilising carbohydrate as any average subject. The sugar in his urine was accidental, and the acetone was produced by his strict protein diet in the manner to be described later on. I quote this case simply to show that it is quite impossible in certain

patients to decide by clinical investigation whether they are diabetics or not. In such patients, examination of the urine gives little or no helpful information. Sugar is present, and that is all we can say. What the significance of the sugar is can only be ascertained by a blood-sugar examination. In the investigation of glycosuria we nowadays pay little attention to the urine, but devote our energies to the blood instead. By this means we obtain information which urine examination is incapable of furnishing. Indeed, it may be said with truth that examination of the urine is of comparatively little value in any doubtful case of glycosuria, and the fashion of giving long detailed analyses of various constituents, so prevalent on the continent, is devoid of value, at any rate as far as the patient is concerned. With regard to urinary examination, I have been very much struck by the fact that many medical men assume that a patient whose urine gives a slight reaction with Fehling's solution is more likely to be a diabetic subject if the urine passed is of high specific gravity. Exactly the reverse is true. It is common knowledge that the urine in bad cases of diabetes is usually of high specific gravity, but this is due entirely to the large amount of sugar in solution. In urines of high specific gravity giving but a slight sugar reaction, and therefore containing at most only a small amount of sugar, this reaction is more likely to be due to concentration than anything else. A urine showing a small amount of sugar, but of very low specific gravity, would be more suspicious. In every doubtful case of glycosuria it is essential that the patient's blood-sugar should be investigated, for when this is done, we can generally ascertain what the nature of the glycosuria is, and to what extent carbohydrate metabolism is interfered with.

Our knowledge of the changes which the blood-sugar undergoes both in normal and diabetic subjects has been obtained very largely from investigations pursued during the last few years. Much of this knowledge is therefore new, and some of it we do not yet fully understand. However, recent methods of blood-sugar investigation, by which the blood-sugar concentration can be ascertained when using only a few drops of blood, have contributed largely to a more complete understanding of the mechanism by which glycosuria is produced. It may be said at once that a knowledge of the changes which the blood-sugar undergoes as the result of food and other factors is so important that no medical man can ever have other than an empirical conception of glycosuria and the manner in which it is produced unless he is conversant with this recent knowledge. A few hours spent in mastering the somewhat elementary details connected with the subject will well repay him, for he will then understand clearly many points connected with glycosuria and diabetes which were formerly dark and obscure. For everyone who treats diabetic patients with the new remedy insulin it is imperative that these blood changes should be understood, and they will now be briefly described.

Blood-Sugar in the Normal Subject.

Since the blood-sugar variations in the normal individual must be appreciated before we can understand the changes found in the diabetic, it is necessary to deal first with the normal subject. In the normal healthy person the blood, when examined three or four hours after a meal or in the morning before breakfast, will be found to contain about 0.1 per cent. of sugar. This value varies to some slight extent in different individuals, but, speaking generally, it lies between 0.09 and 0.11 per cent. Under certain circumstances it may be a little higher, or even a little lower than this, but the round figure of 0.1 per cent. (100 mg. sugar per 100 c.cm. blood) is generally accepted as the normal for average individuals. Formerly there used to be an idea that blood-sugar concentration remained practically constant, and never varied to any appreciable extent, but we now know that this is an erroneous view, and that as the result of food and other factors the blood-sugar is constantly changing from time to time. These changes

are best observed when the blood-sugar is estimated at short intervals after a meal of starchy food or sugar.

Blood-Sugar Variations in the Normal Subject After Ingestion of Carbohydrate.

If we take a healthy adult and estimate his blood-sugar three or four hours after a meal it will, as already indicated, nearly always be in the region of 0.1 per cent. If we now give him, say, 50 g. of glucose by mouth, and examine

FIG. 1.

Blood-sugar curve obtained from normal individual.

hydrate diet. After an ordinary mixed meal, the blood-sugar rises very considerably within the first half to three-quarters of an hour; it then decreases, and within one and a half to two hours after taking a meal, it once again returns to the region of the normal value. A sugar curve obtained from a normal individual is shown in Fig. 1; here 50 g. of glucose were taken.

From the above short description it will be obvious that the amount of sugar found in the blood depends chiefly on the time the sample of blood is withdrawn with reference to the diet. It is very important to be quite clear on this point, for a blood-sugar of, say, 0.17 per cent. would be of no significance whatever if found shortly after a mixed meal had been taken, but would be of definite significance if found in a patient who had taken no food for several hours beforehand. Since all our ordinary diets contain a certain amount of carbohydrate, the blood-sugar concentration is constantly increasing and decreasing during each day, in correlation with our meals.

The Extent to which the Blood-Sugar can be Raised in the Normal Subject.

In the average normal individual it is practically impossible to raise the blood-sugar above 0.17 to 0.18 per cent. The exact amount varies somewhat with different individuals, and occasionally the value may lie a little higher than the figures just given, but, generally speaking, it will be found that the blood-sugar cannot be raised above a maximum of 0.2 per cent., however much starch or glucose be taken. Thus a dose of 50 g. of glucose given to a certain subject raised the blood-sugar to 0.17 per cent. after 30 minutes, while, on another occasion, in the same subject, a dose of 250 g. gave exactly the same blood-sugar value when examined at a similar interval after the dose; this was the maximum point to which the blood-sugar rose in both instances. The only difference was, that with the larger dose of glucose the high value was maintained for a slightly longer period. On both occasions the blood-sugar was 0.1 per cent. after two hours. From this it will be obvious that it is generally impossible to produce glycosuria in the normal subject by feeding with excess of sugar. Indeed, patients have taken nearly a pound of sugar

at once without any glycosuria being produced. There is therefore, strictly speaking, no such condition as the so-called "alimentary glycosuria," for if glycosuria succeeds an excessive ingestion of sugar or starch, it generally indicates that the patient's mechanism for dealing with sugar is defective. No doubt, excessive amounts of sugar may occasionally induce a slight glycosuria in a healthy subject, but such doses are difficult to take, and generally produce nausea and vomiting. We may, therefore, accept it as proved that excessive ingestion of carbohydrates does not per se produce glycosuria. When very large amounts of carbohydrate are taken over long periods glycosuria may result in some subjects, but this appears to be caused by a long-continued strain on the carbohydrate storage mechanism—a strain which ultimately injures the mechanism and results in a condition which is essentially a potential diabetes, and which frequently leads to a well-marked clinical diabetes.

The Mechanism which Prevents Glycosuria After Ingestion of Sugar.

The fact that sugar taken by the mouth will not, as a rule, raise the blood-sugar beyond the limits mentioned, however much sugar is taken, suggests that there must be a definite mechanism which removes the sugar from the blood when it rises to this point. It might, of course, be argued that what happens is much simpler, and that the chief cause of the drop is lessened absorption from the intestine. That this is not so is quite certain, for it has been shown that absorption goes on steadily for a long time after the blood-sugar begins to fall; that, indeed, the blood-sugar may have returned to a normal or even subnormal value with absorption still going on rapidly all the time. The mechanism which prevents the blood-sugar rising to any appreciable extent in the normal subject probably resides in the liver. All the absorbed sugar has to pass through this organ before it gets into the general circulation, and it would appear as if the liver at first allowed a certain amount to pass through but that, whenever a concentration of about 0.18 per cent. is reached, then the liver begins to store sugar, and so removes it from the blood. It is most interesting to remember that this figure—approximately 0.18 per cent.—is just about the maximum concentration which can be present in the blood without any sugar being removed by the kidneys. Whenever the blood-sugar exceeds 0.18 per cent. the kidneys throw out the excess. There is thus a very definite reason why the blood-sugar should not be permitted to rise above a certain value in the blood for a high concentration of blood-sugar would simply result in a great loss of sugar by the kidney. This maximum blood-sugar value of about 0.18 per cent. is known as the renal threshold value for sugar, and represents the concentration below which no sugar is excreted into the urine. This renal threshold value, however, sometimes varies to some extent, even in perfectly healthy individuals, and when it is lower than normal it gives rise to the condition known as renal glycosuria, which will be fully described later.

Blood-Sugar Reactions in the Diabetic Subject.

When sugar is given to a diabetic patient the results obtained in the blood are very different from those in the normal individual. In the former the blood-sugar is generally higher than the normal 0.1 per cent. to begin with, but if it is reduced to this region by dieting, and then a dose of 50 g. of glucose is given, the blood-sugar rises steadily for an hour or two, the intensity of the rise being dependent on the gravity of the case. In the diabetic there is often little or no evidence of any mechanism for preventing the blood-sugar rising above the normal threshold value of approximately 0.18 per cent., and so glycosuria results. Generally, in a fairly severe case, the blood-sugar rises to 0.3 per cent. or more within one and a half hours to two hours. Here the usual mechanism is in abeyance, and in every case of diabetes the blood-sugar rises much higher than it ever does in the normal. This, however, is not the most striking

difference between the healthy and diabetic patient, for in the latter the blood-sugar fails to return for many hours or perhaps not at all, to the concentration present at the beginning of the experiment. The typical diabetic blood-sugar curve is therefore characterised by an increase of blood-sugar well above the renal threshold value, together with a very great delay in the return of the blood-sugar content to an approximately normal level. These two phenomena generally go together, but during the earlier stages of diabetes, when glycosuria is as yet only intermittent, it is

FIG. 2.

Diabetic (upper) curve compared with normal (lower) curve.

found, that though the blood-sugar concentration may never exceed the normal threshold value, the curve is much prolonged. In such cases it may take three or four hours for the blood-sugar to resume its normal level after a dose of 50 g. of glucose has been taken. Indeed, it is certain that one of the earliest indications of diabetes is a prolongation of the time required for the blood-sugar to return to normal

this glycosuria at once ceases. The absence of sugar in the urine, therefore, does not tell us whether the blood-sugar is subnormal or nearly as high as 0.18 per cent. What we do know is, that in people with normal kidneys, glycosuria cannot occur unless the blood-sugar is at least as high as 0.18 per cent. or rather more. It will thus be seen that there is not necessarily any essential virtue in keeping the urine just free from sugar, for in one patient with 0.19 per cent. blood-sugar, glycosuria might be present, while in another patient with, say, 0.18 per cent. blood-sugar, no glycosuria would be seen. The border line, so to speak, is a narrow one. This point is frequently forgotten in connexion with the treatment of diabetes, but it shows the advantage of blood-sugar estimations whenever these can be carried out. In some patients, and more especially in elderly individuals, the renal threshold value for sugar may be very considerably raised, so that even 0.3 per cent. or more sugar may be present in the blood without any glycosuria. In such patients urine examination is most deceptive, and effective control can only be exercised by means of blood-sugar investigations. A few examples of the results of sugar-tolerance tests in diabetic patients are given in Table I.

TABLE I.—Blood-Sugar Before and After Glucose.

Case.	Before.	Half hour after.	One hour after.	Two hours after.
1	0.124	0.193	0.281	0.245
2	0.162	0.235	0.321	0.290
3	0.120	0.192	0.224	0.162
4	0.320	0.451	0.426	0.391

RENAL GLYCOSURIA.

Though the normal average kidney does not permit of the passage of sugar until a concentration of over 0.18 per cent. is reached in the blood, there are many individuals whose kidneys will allow sugar to pass when the blood concentration is much lower than this. Since the blood-sugar always rises after a mixed meal, it is obvious that these subjects will tend to pass sugar after every meal. Instead of the normal threshold value, these patients may have a threshold value represented by any blood-sugar concentration between 0.1 or less and 0.18; obviously, glycosuria is a necessary feature of this condition. Renal glycosuria means simply that the kidneys allow sugar to pass through into the urine at a level of blood-sugar concentration that is much lower than usual; this blood-sugar concentration, however, is always within physiological limits, so that the only organs participating in the production of this condition are the kidneys. A similar condition can be induced experimentally by giving phloridzin. In this case, large amounts of sugar are passed in the urine, but, on examination, the blood-sugar will be found to be very low. A somewhat similar phenomenon is also very common during the first few months of pregnancy, the glycosuria so frequently encountered through this period being dependent on a temporary lowering of the renal threshold.

In these renal cases the sugar-tolerance curve is quite typical, for the highest point reached never exceeds the normal threshold value, and frequently the rise is very much less than normal. This results from the fact that sugar, which will normally accumulate in the blood and so raise the blood-sugar concentration, is thrown out in the urine. In other respects the curve behaves just as the normal does. After taking 50 g. of sugar by mouth the blood-sugar returns to the normal level in from one and a half to two hours or perhaps earlier, and the glycosuria then ceases. The mechanism of renal glycosuria is a simple one to understand, though the exact condition in the kidney which causes it is at present obscure. The amount of sugar passed in the urine in such cases depends principally on the exact concentration at which the kidneys begin to throw out sugar. Other things being equal, the lower this blood-sugar concentration, the more sugar will be excreted. There is no advantage to be

after a dose of glucose. As the malady progresses this is accompanied by a marked increase in the height of the curve as well. The curve obtained from a moderately severe case of diabetes after the ingestion of 50 g. of glucose is given in Fig. 2. The contrast between this and the normal curve shown alongside is very striking.

Sugar-Tolerance Tests in Diabetes.

Based on the above principles, various tests have been suggested to ascertain whether or not any given case of glycosuria is really diabetic. The so-called sugar-tolerance test which consists in giving to a patient about 50 g. of glucose dissolved in 2 or 3 oz. of water, and then estimating the blood-sugar at half-hourly intervals for two hours, is perhaps the most satisfactory method. The patient should have no food for two or three hours beforehand, and must not eat or drink during the test. If, after taking 50 g. of glucose the blood-sugar comes back to approximately the normal value of 0.1 per cent. within two hours of taking the glucose, then the case is not one of diabetes. For various reasons it is more satisfactory to do half-hourly blood-sugar estimations in these cases, but the same information can generally be obtained by means of a single blood-sugar estimation carried out on a patient two hours after the ingestion of 50 g. of glucose. If his blood-sugar is then approximately normal he is not a diabetic. In every healthy person the blood-sugar will be found to be normal after this period. In a certain number of elderly people the fall may be delayed to some slight extent, but in young and middle-aged subjects the blood-sugar ought generally to be back to normal in one and a half hours. It is this return to normal within a certain period that is most important in the interpretation of sugar-tolerance tests, though the maximum extent to which the sugar concentration rises in the blood also gives a good deal of information.

The Relation of Blood-Sugar to Glycosuria.

It will now be obvious that when glycosuria occurs the blood-sugar must be higher than 0.18 per cent.; whenever it gets to even a slightly lower level than

gained in endeavouring to divide renal glycosuria into different types, for this only tends to confuse a perfectly straightforward issue; there is, indeed, no essential difference between one case of renal glycosuria and another, except in so much as the excretion of sugar depends on what the level of the renal threshold happens to be in any particular patient. The figures given in Table II. show the results obtained by sugar-tolerance tests in some cases of this nature; in each instance 50 g. of glucose were given.

TABLE II.

Patient	1	2	3	4	5
Blood-sugar per cent. before taking glucose ..	0.091	0.108	0.116	0.123	0.100
After $\frac{1}{2}$ hour	0.132	0.176	0.168	0.187	0.142

Urine-sugar per cent.—					
Before test	0.25	0.30	—	0.70	Traces
After test	2.1	3.5	0.6	1.3	2.2

It will be quite obvious that so-called renal glycosuria has nothing whatever to do with diabetes. That the condition is quite harmless seems to be proved by the fact that several patients have been examined, who are known to have had glycosuria for many years. The slight loss of carbohydrate may be a disadvantage, but practically this is never so great as to be of much importance. It is possible, of course, for a diabetic to have a lowered renal threshold, but such a condition is rare, though I have seen two cases of this nature. In contrast with the general impression at present prevailing, renal glycosuria is by no means a rare condition, and many patients now being treated as diabetics are suffering from nothing more serious than this complaint. Within the last four years I have examined more than 100 patients suffering from renal glycosuria. In not a few instances these patients were supposed to be diabetic and were being treated accordingly. The condition is frequently a familial one and may be sometimes traced back for several generations. It may occur in several members of the same family. As an indication of the great frequency of renal glycosuria I might state that it is now our custom at St. Thomas's Hospital to get all the students to carry out sugar-tolerance tests on themselves before allowing them to investigate patients. In every class we have had during the last few years we found from one to three students suffering from renal glycosuria. In addressing medical men on glycosuria it has nearly always been my experience that at least one doctor approached me after the lecture to tell me that he himself suffered from the condition. The glycosuria which is so frequently discovered accidentally during a life insurance or other medical examination is frequently found to be of renal origin, but in order to ascertain definitely what any glycosuria indicates, it is necessary to examine the blood and to carry out a sugar-tolerance test. Without exception such a test will settle the matter as far as renal glycosuria is concerned.

Another Mechanism in the Production of Glycosuria.

In some patients whose power of dealing with carbohydrate is quite efficient, glycosuria, other than that of renal origin above described, may occasionally be present. When a sugar-tolerance test is carried out on such patients it will be found that the blood-sugar rises considerably higher than the normal threshold value, and in this way simulates an ordinary diabetic curve. Instead, however, of remaining high, the blood-sugar quickly falls, and in one and a half hours or so reaches the normal level. Unlike what happens in diabetes, there is no difficulty whatever in removing the sugar from the blood once the sugar storage mechanism gets into play, but this mechanism appears to be delayed, so that the blood-sugar is allowed to rise above the threshold value for a short period, with the result that glycosuria follows. The very nature of the

curve obtained (see Fig. 3) is an indication that carbohydrate metabolism is quite efficient, since the curve is not in the least prolonged. The exact significance of this condition is at present not understood, but it does not seem to be in any way prejudicial to the patient.

The condition is not of common occurrence, but is rather puzzling when met with. In my monograph on diabetes I have applied the term "lag" to a typical curve of this nature, on the assumption that the phenomenon is due to a delayed activity on the part of the sugar storage mechanism.

Some General Observations on Glycosuria.

Although the typical curve obtained by testing a diabetic patient by the sugar-tolerance test is a high, and especially a prolonged one, various conditions, other than diabetes, will in some measure produce the same type of curve. In practice it is found that one prolific source of glycosuria is immoderate use of alcohol. Alcohol apparently acts on the liver and tends to deplete the glycogen reserve, so that it is by no means uncommon to find sugar in the urine after a dinner in which alcohol plays a part. The effect of emotional disturbances and excitement in producing glycosuria is now well recognised. Possibly the glycosuria sometimes found during the medical examination of a patient may be nothing more than an indication of mental excitement and nervousness. Certain drugs also will produce glycosuria, especially thyroid extract, and the occurrence of glycosuria in endocrine disorders is familiar to all. In any case of glycosuria the medical man should attempt to elucidate such possible factors as those mentioned. Frequently he will have his reward, for by eliminating the aetiological factor, the glycosuria will disappear. In general it must be remembered that glycosuria, like albuminuria, may be an important feature, or it may be of no significance; it bears roughly the same relation to diabetes as albuminuria does to nephritis. Glycosuria is relatively common, while diabetes is, on the whole, a comparatively rare disease. This must mean that glycosuria has no essential relationship to diabetes, just as albuminuria is no definite indication of the presence of nephritis. Both conditions, when found, should be regarded as possibly important symptoms, but in neither case should the medical attendant rest content until he has done all he can to elucidate the cause. On finding glycosuria in a patient showing no definite symptoms of diabetes, a sugar-tolerance test is always indicated. Were this more frequently carried out many patients with glycosuria would be found to possess quite good powers in metabolising carbohydrate, and frequently the patient could be assured that his glycosuria would do him no harm. If, on the other hand, the result of such a test should suggest the presence of an early diabetes, prompt and efficient treatment gives the best chance to the patient. We can no longer rely on examination of the urine in such cases, and if we wish to get the best result we must have recourse to blood examination.

The Estimation of Blood-Sugar.

Since the introduction of the insulin treatment for diabetes, it is more than ever necessary that medical men should be able to carry out blood-sugar estimations. This will be referred to later when dealing with insulin. For the present, sufficient has been said as to the value of such investigations in all cases of glycos-

FIG. 3.

A typical "lag" curve.

uria, and the only question that arises is whether it is possible for the average medical practitioner to estimate the blood-sugar. It is quite true that many of the methods used for this purpose are elaborate, and quite unsuitable for anyone who has not a well-equipped laboratory at his disposal. Many of these methods necessitate the use of a colorimeter, and experience shows that colorimetric methods, while excellent in the hands of the trained observer working in a laboratory, are unsatisfactory for the general practitioner. Another objection to their use is the costly nature of the apparatus. For general use the apparatus must not be expensive, and the method must be simple and reliable. The writer has worked out a method¹ for the estimation of blood-sugar which can be performed by any medical man possessing the minimum of chemical knowledge and laboratory equipment, provided he has a little time at his disposal. The ease with which this method can be carried out with satisfactory results is obvious from the fact that our students, when doing it for the first time, almost invariably get correct results. In a class of 25 students or so carrying out observations on themselves the results generally vary from 0.09 to 0.12 per cent.—numbers which represent the ordinary blood-sugar values. The apparatus necessary may be obtained for a few pounds, and it is doubtful whether a simpler method can be evolved. Its accuracy has been amply substantiated both at home and abroad and the method is now in general use in many institutions in this country. It is also being used with success by several medical men in general practice; even when done roughly it will give results sufficiently accurate for clinical purposes.

TREATMENT OF DIABETES.

As soon as the diagnosis of diabetes is definitely established, we should begin treatment at once. Before the modern insulin treatment came into vogue we had to rely almost entirely on dietetic means, for no drug possesses the slightest beneficial influence on the condition. Contrary to a widespread belief, dietetic restrictions are just as essential when insulin is used as ever before, and it is important that the principles of modern dietetic treatment should be utilised in conjunction with the insulin treatment. For this reason a few points on diet in diabetes will be very shortly discussed here.

The dietetic treatment in vogue at present is associated with the name of Allen, and despite many claims by various observers it must be admitted that to Allen alone belongs the credit of having introduced more rational measures in dieting diabetic patients. The merit of Allen's work lies essentially in the fact that he alone brought forward experimental evidence for his conclusions. Allen removed the greater part of the pancreas from dogs, leaving behind a small portion of the organ intact. He found that the ultimate fate of such dogs depended on the diet. When a dog with a very small amount of pancreas was fed on a high diet, whether of carbohydrate or protein or fat, it gradually began to pass sugar in the urine, and soon developed all the symptoms of typical diabetes, with the result that death from coma took place. Such a dog, when fed on a low diet, maintained good health and showed no signs of diabetes. It thus became obvious that in the case of partially depancreatized dogs, the best way to maintain health was to give the lowest possible diet for the needs of the animal. Unfortunately, the condition of a dog with a small but healthy part of his pancreas left is essentially different from that of a person suffering from diabetes. In the latter case the disease is dependent on some change entirely different from the experimental removal of part of the pancreas, and is essentially progressive, otherwise the disease would never have manifested itself. That this progressive tendency can be accelerated by unsuitable diet is certain, but the

point to remember is that in human diabetes two factors are present: (1) An essentially progressive lesion absent in experimental animals; and (2) the detrimental effect of improper diet.

If the tendency to progression of the disease is very marked, dietetic treatment will not prove very satisfactory, but if, as frequently appears to be the case, this factor is not a very active one, then dietetic treatment will give excellent results. Consideration of these points will help us to understand why modern dietetic treatment alone frequently leads to disappointment. In such cases insulin gives wonderful results, and this is the type of case in which insulin will be most beneficial.

Some Principles of Modern Dietetic Treatment.

Briefly stated, modern dietetic treatment of diabetes consists in giving to the patient the minimum amount of food which will enable him to keep fairly fit and free from glycosuria, and, if possible, from acetonuria. To do this it is necessary to ascertain what amounts of the three ordinary classes of foodstuffs—carbohydrates, proteins, and fats—should be present in the diet. The subject is fully discussed in my monograph on Diabetes and Glycosuria, but the principles on which the diet should be built up will be referred to here very shortly.

The Building up of a Suitable Diet.

The first point to be considered is, What is the necessary minimum amount of food that would be required as a permanent diet for any given patient? It is now the custom to express food values in terms of calories, and for clinical purposes it is sufficiently accurate to assume that 1 g. carbohydrate = 4 calories; 1 g. protein = 4 calories; 1 g. fat = 9 calories. The total number of calories necessary for any given patient is calculated from the fact that for every pound of weight he will require roughly from 12 to 15 calories. Thus, a man weighing 140 pounds would require, as a minimum, from 1700 to 2000 calories, and in ordinary life would probably eat sufficient to give a good deal more than this. When the patient is leading a very sedentary life, he can sometimes get on fairly well with even less than the above minimum. Having ascertained the number of calories necessary, it is now essential to decide what amounts of the different classes of foodstuffs should be given to make up the requisite calories.

Amount of Protein Necessary.

Whatever the nature of the diet, it is necessary to give some protein, and experience shows that the minimum amount of protein necessary for health is about one-half a gramme per day for each pound the patient weighs. In a patient weighing 140 pounds it will therefore be necessary that his permanent diet should contain at least about 70 g. of protein.

Amounts of Carbohydrate and Fat Necessary.

It is very rare to find a diabetic patient who can take more than 80 to 100 g. of carbohydrate per day without passing sugar, and the great majority of severe cases can generally utilise not more than half of this amount. Some patients, indeed, can take only a very few grammes of carbohydrate per day. The exact amount suitable for each individual patient is ascertained by the usual well-known method of starving the patient until the urine is sugar-free, and then giving a series of diets containing increasing graduated amounts of all three foodstuffs. When sugar appears in the urine it may be assumed that the amount of carbohydrate contained in that particular diet is roughly the maximum which the patient can assimilate, and it is well to give rather less than this amount. For a permanent diet, the remaining calories must be made up from fat. For example, a patient weighing 140 pounds and therefore requiring a diet containing at least about 1700 calories, was found to pass sugar when on a diet consisting of 40 g. of protein and 40 g. of carbohydrate together with some fat. This patient's protein was ultimately increased to 70 g., and with

¹ For a complete description of this method see my monograph, "Modern Methods in the Diagnosis and Treatment of Glycosuria and Diabetes," 1922 (Constable and Co., Orange-street, London). Many of the points referred to in this paper are more fully discussed in this book.

this 30 g. of carbohydrate were allowed, the necessary calories being made up by giving 150 g. of fat.

Food Values.

Many books dealing with food values are now obtainable, but for practical purposes I have found the following tables to be most useful; indeed, little more is required for the treatment of diabetes. As they may prove helpful to the general medical man I give them here. By their use a suitable diet can be made out for almost any patient.

TABLE III.—Showing Carbohydrate Content of Various Vegetables and Fruits.

Group.	ONE OUNCE CONTAINS—	
A	1 g. ch.	Cabbage, cauliflower, Brussels sprouts, lettuce, spinach, cucumbers, asparagus, marrow, rhubarb, celery, mushrooms, tomatoes, water-cress, seakale, leeks, radishes, grape fruit, endive.
B	2 "	Carrots, onions, turnips, beets, French beans.
C	3 "	Oranges, strawberries, gooseberries, cranberries, peaches, pineapple, water melon.
D	4 "	Green peas, artichokes, parsnips, pears, apples, currants, cherries, raspberries, apricots.
E	6 "	Potatoes, plums, prunes, bananas.

g.ch.—grammes carbohydrate.

THE INSULIN TREATMENT OF DIABETES.

Insulin is a substance of unknown nature derived from the islands of Langerhans in the pancreas. The method of preparation of this product is somewhat tedious and laborious, but the principle of its isolation depends on a process of fractional precipitation with alcohol. By this means certain deleterious and irritating substances are left behind, and the insulin ultimately obtained in a form more or less suitable for clinical purposes. Various methods of purification of crude insulin are employed, and it may be said at once that the substance can now be prepared in such a state of purity that no local reactions follow its use. *Insulin must be given hypodermically*, and is of no value when given by mouth. In this connexion it is safe to assert that none of the pancreatic preparations given by mouth have any beneficial effect on diabetes, whatever other action they may possess. In the preparation of insulin great care has to be exercised to ensure that the product is sterile, for it is obvious that contamination of the ox pancreas, from which the insulin is prepared, by intestinal contents, might result in infecting the patient. All these difficulties, however, have been overcome and quite reliable insulin is now being prepared commercially. In this connexion the thanks of the community are due to the Medical Research Council, who took steps to control and promote the manufacture of insulin in this country, with the result that the samples now being made here are reliable in strength and action. Were it not for the measures taken by the Medical Research Council it is probable that the

country would now be flooded with useless preparations, and an excellent remedy might have fallen into disrepute.

Dosage of Insulin.

The strength of insulin preparations is at present ascertained by means of rabbit experiments. The amount of insulin required to bring the blood-sugar of a large starved rabbit to about 0.04 per cent. in two hours or so is taken as the basis of unitage. Generally, when the blood-sugar reaches this level, the animal goes into convulsions. These can be stopped by the introduction of sugar into the rabbit's stomach by a tube or by injection into the system. The amount of insulin required to produce the above effects in a rabbit is equivalent to about three units, according to the new nomenclature, and an ordinary minimum human dose is taken as representing three to four times this amount, or about 10 units. In many patients, of course, much larger doses may be given with impunity. Unfortunately, different rabbits vary very much in their response to insulin, so that the method of standardisation just described is not a very accurate one. Patients also vary to a great extent. It is important to have all insulin preparations standardised as carefully as possible, so that the different samples on the market may all have approximately the same strength. On the other hand, extreme accuracy is at present impossible, and however desirable scientifically, is not essential for the clinical use of insulin. Indeed, the present standardisation seems quite efficient for all practical purposes.

Some Symptoms Produced by Insulin.

Insulin is a powerful remedy, and in the hands of the inexperienced may give rise to certain difficulties. When an overdose is given, the patient frequently complains of certain curious symptoms which generally come on from an hour to a few hours after the injection. These symptoms consist of flushing, giddiness, local sweating, a sense of constriction about the chest and abdomen, collapse, and other manifestations; if this condition is unrelieved convulsions may follow. These symptoms appear to be of nervous origin, and are dependent on the fact that the central nervous system requires its nutrient blood to contain a certain amount of sugar. When, as the result of the action of insulin, the blood-sugar sinks to the neighbourhood of 0.04 per cent., the above symptoms ensue, and convulsions may set in. Addition of sugar to the depleted blood will at once remove all symptoms, so that there is little or no real danger if the patient is carefully warned to take sugar by mouth whenever any symptoms, such as those described, follow the injection of insulin. Sugar, when given by mouth, reaches the blood in a very short time, but it may, of course, be necessary to inject sugar intravenously in the case of an unconscious patient.

Effect of Insulin on the Diabetic Condition.

Insulin acts in tending to restore the diabetic patient to the condition of the normal individual. Apparently, in diabetes, a substance essential for carbohydrate metabolism is missing or present in insufficient amount, and the injection of insulin supplies this missing secretion. Consequently, in diabetes the therapeutic use of insulin results in a disappearance or lowering of the urinary sugar and ketone bodies. In subjects whose diets are carefully correlated with the insulin dosage, the blood-sugar may be kept within normal limits, and the urine free from sugar and ketone bodies. Very careful adjustment of diet to insulin is, however, required to produce this effect and frequent estimations of blood-sugar may be essential. It may be taken as a general rule that insulin will produce no deleterious effects as long as glycosuria is present, so that it is easy and safe to regulate the dosage by examining the urine. When sufficient insulin is given to render the urine sugar-free, the condition of the urine does not help us any more, and recourse must be had to blood-sugar examinations. Indeed, blood-sugar estimations are

almost essential in treating patients with insulin, but as circumstances might arise in which they could not possibly be done, it may be helpful to state that they are not absolutely necessary in all cases. Without the means of ascertaining the blood-sugar content, it is true that one is, to some extent, working in the dark, and it is to be hoped that every practitioner using insulin will make himself efficient in performing this comparatively simple manipulation. To begin with, however, this ideal result may not be easily reached, and as it is most important to prevent the occurrence of possible tragedies at this stage of the treatment, the following rules, based on my own experience of the remedy, may be found helpful in the treatment of patients. Many modifications of these suggestions may be made and they are only given as a general outline.

Rules for Treatment of Patients with Insulin.

1. Always make quite certain that the case is really one of diabetes. It is somewhat dangerous to treat certain cases, such as the renal glycosuria already described with insulin, since the blood-sugar in these may be already somewhat low. To exclude renal glycosuria give the patient a dose of glucose or ordinary cane-sugar (50 grammes) and get him to empty his bladder two and a half to three hours after the ingestion of the glucose; test the next specimen of urine passed for sugar. If sugar is then absent, or only a small amount is present, the case is not suitable for insulin, since the glycosuria is probably of renal origin. Also examine the urine for acetone and diacetic acid. If acetone is not present, the patient does not require insulin. Here it should be noted that acetone may be present in the urine of any patient if his diet has been recently changed to one containing a good deal of protein and fat and little carbohydrate. If possible, do a blood-sugar estimation, when the exact state of matters will be more or less obvious. Inquire carefully into the history of the patient and ascertain whether he has lost weight, and whether well-marked symptoms of diabetes are present. If he has not been dieted before, and is found to be suffering from diabetes, try the effect of diet before giving insulin; in such cases insulin may be used with advantage instead of the old starvation treatment, to bring the blood-sugar back to normal, at the early stages of treatment. When this happens insulin should be stopped, and, gradually, diets on the lines already described given. When a patient is doing fairly well on diet insulin should not be given.

2. Having decided that the patient is a suitable case for insulin, it is necessary to arrange matters so that he may be under observation. Give him a diet containing the necessary amount of calories for his weight, or rather somewhat less than this, and let the diet always contain from 30 to 40 grammes of carbohydrate. Divide the diet into two large meals in which practically all the carbohydrate is taken, and two small meals containing little or no carbohydrate and only a few calories. Warn the patient carefully that symptoms may possibly come on after the insulin injections, and tell him to eat a few sticks of barley-sugar ($\frac{1}{2}$ to 1 ounce) if these symptoms do come on. To provide against delay in taking sugar under these conditions, see that the patient has always a small stock of barley-sugar or other suitable preparation on his person.

3. Begin the treatment by injecting 10 units of insulin twice a day, 20 to 30 minutes before the large meals. Collect the 24 hours' urine and examine it for sugar. Continue this dosage for three days, when, if the urine still contains sugar, 15 units of insulin may be injected twice a day instead of 10 units. If after three more days of this treatment glycosuria still persists, the dose may be increased to 20 units in the morning followed by 15 units in the evening. If glycosuria persists after a few days of this dosage, give 20 units twice a day. If glycosuria now disappears, the dose is approximately correct for the diet, but unless facilities for blood-sugar estimation are available, it might now be safer to revert to a dose of 15 units in the morning followed by 15 units at night. This may be continued for a long period, but the same diet must be carefully adhered to. If the diet is deemed insufficient, a little more carbohydrate may be added to the two larger diets, and if this produces glycosuria the dose of insulin may be gradually increased in order to ascertain what amount will result in a urine with just a very small amount of sugar. If at all possible control the treatment from time to time with blood-sugar estimations. Unless this can be done, a dose of 20 units twice daily should perhaps not be exceeded, or, at any rate, should only be increased very carefully and gradually. The diet and insulin dosage of one of my cases is recorded below. The patient, a young adult, was suffering from the effects of severe and long-continued diabetes. On the régime given he is

free from glycosuria, and shows only very slight acetoneuria. He feels quite fit and is doing fairly heavy manual work.

Régime for Adult Patient Doing Fair Amount of Manual Work.

9.30 A.M.: Injection of 20 Units Insulin.

BREAKFAST.

9.45 to 10 A.M. :—	Carb.	Prot.	Fat.	Cal.
$\frac{1}{2}$ oz. oatmeal as porridge				
1 egg

$\frac{1}{2}$ oz. olive oil				

Total 56 .. 84 .. 164 .. 2036

With any of these diets the patient may take tea, coffee, or beef-tea in as large a quantity as desired.

THE VALUE OF INSULIN AND THE GENERAL OUTLOOK.

I have now treated nearly 20 patients suffering from severe diabetes and in every case with entirely satisfactory results. No untoward symptoms of any kind occurred in any case. Patients who were almost moribund a few months ago are now back at work, and three subjects who were first seen while in a state of diabetic coma are now quite fit. There can, therefore, be no question of the great value of the remedy. Its principal drawbacks are that it does not cure, but merely alleviates the condition while it is being given, and the fact that it has to be administered hypodermically. No doubt, in comparatively recent acute cases, its use may occasionally result in a return of tolerance, just as was sometimes the case with dietetic treatment, and I have seen one case of this kind, but it is impossible to say whether the same result could not have been achieved by diet. Since, however, this boy was actually in coma when I first saw him, insulin was naturally used. He is now taking quite a large diet with one single small dose of 5 units of insulin per day, and is apparently normal with a resting blood-sugar of about 0.1 per cent. and no glycosuria or ketosis. In long-established disease I have seen no signs of increase of tolerance after insulin, and should doubt whether, in such cases, much is to be hoped for in this direction. What exactly the future of insulin will be it is impossible to say. That its advent has provided the greatest therapeutic measure in the treatment of diabetes is certain. Probably many patients will ultimately learn to inject themselves, or make some arrangement for a friend to do this for them. Insulin is almost exactly on the same footing as thyroid extract in the treatment of myxœdema, with the disadvantage that insulin cannot be taken by mouth. That it is capable of eliminating the symptoms of diabetes and restoring strength and energy to the unfortunate sufferer is now definitely established.

SOME GENERAL OBSERVATIONS.

The suggestions given for the use of insulin may be modified almost indefinitely, but the principle of correlating diet to insulin dosage must always be observed. If the rules given are carefully adhered to, it would seem that there is no great danger in the use of the remedy. Care must, of course, be taken that the patient is not allowed to fast too long after the injection, but this is an obvious point.

One of the most striking features of insulin treatment is the rapidity with which patients put on weight; it is no uncommon occurrence for them to gain a stone in about ten days. Also, in many cases, the ketosis rapidly diminishes, even though fairly considerable amounts of sugar may persist in the urine. Unpleasant symptoms are much more easily produced by insulin in the case of mild diabetes than in the severer types. In my experience, long-standing cases with much wasting and passing very large amounts of sugar and ketone bodies are not likely to show untoward results even when fairly large doses of insulin are given. Such cases frequently stand insulin well. In short, the worse the case the less dangerous does it appear to be to give large doses of insulin. In this respect, it must be observed that many apparently severe cases are really not of a severe nature at all, and often respond very readily to diet. The inexperienced observer might take this condition for a very severe type, but a little care will show that such cases are almost invariably of short duration, and are frequently suffering chiefly from the effects of unsuitable diet. If the case is a long-standing one with severe symptoms and marked glycosuria, insulin may frequently be used with impunity in larger doses than above suggested, but the usual precautions must be taken and graduated doses given at first. With regard to the part played by insulin in the treatment of diabetic coma, it would appear that if the patient is treated before the symptoms become too intense recovery is the rule. Here it is advisable to inject immediately at least 20 units of insulin; this may be followed by another 20 units in a short time if the symptoms do not improve. The usual treatment of diabetic coma, consisting of the administration of large amounts of fluid either by mouth, intravenously, or subcutaneously, together with attention to the bowels, and the other usual procedures should be combined with the insulin treatment. Insulin may be a most dangerous remedy if great care is not taken in its use, but if the dosage given is not large enough to render the urine sugar-free, and if the most strict precautions to ensure that the patient always gets food containing carbohydrate shortly after each dose are taken, then, as far as my experience goes, the remedy would appear to be a safe one.

ON THE MODE OF ACTION OF VITAMINS.

By W. CRAMER, D.Sc. EDIN., PH.D. BERL., M.R.C.S.
(From the Laboratories of the Imperial Cancer
Research Fund.)

IN order to understand the mode of action of vitamins it is necessary to go behind the alterations in growth resulting from vitamin deficiencies. The growth of a highly differentiated animal is affected by so many different intrinsic factors—such as digestive disturbances, infections, and toxæmias, which need not necessarily be virulent and obvious, and alterations in the endocrine organs—that one is not entitled to correlate variations in growth directly with food factors by postulating that these food factors are essential for the general biological process of cell growth, as is done in the case of vitamins, without having excluded the existence of definite pathological lesions which would account for the arrest of growth and for the decline of the animal.

In previous papers¹ my collaborators and I have tried to place the conditions produced by deficiency of vitamins on a pathological basis by correlating the general conditions produced with definite pathological lesions in specific tissues. Thus, we attributed the general marasmus and fall of temperature which occurs when vitamin B is withheld to the atrophy of the lymphoid tissue which then develops. We adduced evidence that in the absence of an actively

functioning lymphoid tissue the absorption and assimilation of food from the intestine is impaired. We found conclusive proof of this view in the fact that when atrophy of the lymphoid tissue is produced by radiation, the same general effect is produced—namely, marasmus and fall of body temperature. We pointed out, further, that it was not only unnecessary to postulate for the vitamins some vague general action which could not be defined, or to assume that the presence of vitamins is necessary for the life of every cell in the body, but that such assumptions were not in accordance with observed facts. We were able also to show² that the assumption inferred in the current conception of the mode of action of vitamins, that these substances have no positive action, was incorrect; an immediate stimulating effect on the processes of food absorption from the intestine could be demonstrated as occurring in perfectly normal animals which had never been subjected to any dietetic deficiency. Here, again, the immediate effect of vitamin deficiency was identical with the effect produced by small doses of radiation. The increased susceptibility to certain types of avirulent infections, which is the characteristic of animals subjected to deficiency in the fat-soluble vitamin A, was found by us always to be associated with a great diminution in the number of platelets. Again, this effect could be produced by exposure to radiation in doses larger than those necessary to produce a lymphopenia, and such radiated animals showed an increased susceptibility to infections.

Intestinal Lesions in Vitamin-A Deficiency.

In searching for the origin of these infections we were guided by the observation that the infections are almost always due to avirulent bacteria, and that the blood or the lymph glands are sometimes found to be infected even when there is no obvious external lesion, such as xerophthalmia. In examining the intestinal tract for changes which might be the starting-point of such infections we have found very definite lesions which are illustrated in the accompanying figures. The sections are longitudinal sections and are always taken from the same place—i.e., the lower end of the small intestine, two inches upwards from the cæcum. This site was selected because any change that does occur appears to be most pronounced in that region. Fig. 1 is the typical appearance of the mucous membrane of rats which have since birth been fed on a vitamin-rich diet. Fig. 2 represents the appearance of the mucous membrane of a rat which had been kept on our ordinary laboratory diet of bread and water, maize, and rice. Such a diet, as stated in a previous paper, enables the rats to grow and breed, but they grow more slowly than the rats kept on a vitamin-rich diet, and succumb more quickly when vitamin A is withheld. We have described the effect of such a diet as "vitamin-underfeeding." Fig. 3 is from a rat which has been kept on a vitamin-A free diet for five weeks and was just beginning to develop xerophthalmia. It shows profound atrophy of the villi and necrosis of the upper parts of many of the villi. Fig. 4 is from a rat in an advanced stage of B deficiency; it had been kept for four weeks on the basal ration plus cod-liver oil, and had a temperature below 35°C. The villi, although differing in appearance from the normal, show no atrophy and no necrosis.

In addition to these gross changes an abundance of protozoa, mainly *Giardia intestinalis* (*Lamblia intestinalis*), are found in the lumen of the intestine of rats in advanced vitamin-A deficiency. These are probably normally present in the intestine in small numbers, but the absence of vitamin A enables them to proliferate rapidly, and to penetrate down between the villi, where normally they are never present. This fact may be of importance in determining the pathogenicity of certain organisms; they may be non-pathogenic on one diet and become pathogenic by variation of the diet. It may also be of use in the experimental infection of animals with such organisms. The intestinal bacteria also appear to be present in

larger numbers than normally, and—what is more significant—can often be seen adherent to the villi, especially the necrotic tips; while normally the bacteria remain confined to the central lumen. A very striking effect seen frequently in the caecum is illustrated in Fig. 5. In the caecum the bacteria often

invade the mucous glands and are found in dense masses filling the lumen of the gland right down to the bottom. In normal rats such a condition may occur exceptionally in a few glands, but in a rat suffering from A deficiency this is the rule, and affects a great many of the glands of the caecum. The figure

FIG. 1.

Small intestine of rat (longitudinal section) kept on a vitamin-rich diet. Rat No. 523 (see Fig. 6). Fixed in formol saline ($\times 60$).

FIG. 2.

Small intestine of rat (longitudinal section) kept on the ordinary laboratory diet. Rat No. 511 (see Fig. 6). Shows the effect of vitamin underfeeding as compared with Fig. 1. Formol saline ($\times 60$).

FIG. 3.

Small intestine of rat (longitudinal section) kept on a diet free from vitamin A for five weeks. Rat 529. Formol saline ($\times 60$).

FIG. 4.

Small intestine of rat (longitudinal section) kept on a diet free from vitamin B for four weeks. Rat 554. Formol saline ($\times 60$).

FIG. 5.

Mucous glands of caecum of rat kept on a diet free from vitamin A. Rat 529 (same rat as Fig. 3). Formol saline ($\times 410$). Stained with Murray's Nile-blue—van Gieson method for bacteria, which are seen filling the lumen of the glands. Note cell division in wall of distended gland.

shows a gland which is actually distended by a mass of bacteria in addition to a few round bodies, probably encysted protozoa. The neighbouring gland, of which only the opening is shown in the drawing, is also invaded by bacteria but not distended. Cestodes, also, are present much more frequently in rats kept on a vitamin-free or vitamin-restricted diet than in rats on a vitamin-rich diet. Rohdenburg and Bullock showed that the cysticerci of *Tænia crassicolis* which form in the liver of rats lead frequently to the development of a sarcoma. Here, again, the diet may be of importance in facilitating the infection.

This intestinal lesion is a further demonstration of the application of the law already referred to, that vitamin deficiencies and exposure to radiations produce the same general effects. For extensive degeneration of the intestinal epithelium has been described by Whipple and his collaborators³ as occurring after exposure to large doses of X rays. It was also observed by Lazarus-Barlow⁴ after exposure to a very large amount of radium, and Mottram has observed it after comparatively small doses of radiation from radium. Mottram⁵ also noticed the proliferation of protozoa and the invasion of the glands of the cæcum by bacteria; he is inclined to attribute the lesion to a disturbance in the secretion of mucus. This effect probably explains the almost regular occurrence of diarrhoea after the application of radiation to the abdomen, and is obviously a factor imposing a severe limitation upon the application of massive doses of radiation to the abdomen.

General Effects Observed in Vitamin-A Deficiency.

This lesion of the intestinal mucous membrane is an adequate explanation of the different general effects observed in vitamin-A deficiency: cessation of growth and occurrence of bacterial infections. Cessation of growth in a young animal must naturally result from an atrophic condition of the intestinal mucous membrane which interferes with the absorption of food. It is equally obvious that such a condition affords the intestinal bacteria a ready access to the tissues and the blood-stream. It is known that one of the mechanisms by which the body defends itself against the invasion of the blood by bacteria—especially avirulent bacteria—is the agglutination of the bacteria by the blood platelets, and that an intravenous injection of such bacteria is followed by a temporary diminution in the number of platelets. In vitamin-A deficiency the progressive atrophy of the intestinal mucous membrane leads to a continued and increasing invasion of the blood-stream by intestinal bacteria which are being agglutinated by the platelets. This continued and progressive drain on the platelets may in itself be the explanation of the thrombopenia which sets in sooner or later in vitamin-A deficiency; or there may be a direct atrophic change in the tissue or cells which form platelets. Observations on the effect of light indicate that the latter alternative is probably correct. Eventually the number of platelets is diminished to such a low level that the defence against the bacteria becomes ineffective.

When vitamin A is supplied again in abundance by giving cod-liver oil the intestinal lesion heals over rapidly; the invasion of the blood-stream by bacteria is arrested, the platelets rapidly increase in number, and the normal defences of the organism are enabled to deal with the avirulent bacteria. We have here again two possible alternatives: cod-liver oil may have a direct stimulating effect on the platelet formation or the increase in number may be due merely to removing the drain on the platelets by arresting the bacterial invasion from the intestine. This will be referred to again in discussing the effect of light on the organism. It is interesting to note that in the healing over of the intestinal mucous membrane, the epithelial cells in the crypts of Lieberkühn are mainly, if not entirely, concerned, since only there can active cell division be seen. I have never seen any mitoses in the villi themselves. It would appear, therefore, that normally the intestinal

epithelium regenerates itself from the cells most deeply situated, very much in the same way as the skin epithelium is regenerated.

Another observation of general importance is that the condition of the intestinal mucous membrane varies, even on natural diets, with the richness of the diet in vitamins. In a stock kept on a vitamin-rich diet the villi of the intestinal mucous membrane are larger and more massive than in a stock kept on our ordinary laboratory diet, which contains just enough vitamins to enable the animals to grow and to breed and to prevent the onset of obvious disease, but has a very restricted content of vitamins. A comparison of Fig. 2 from an animal on such a vitamin-restricted diet with Fig. 1 from an animal on a vitamin-rich diet shows this difference clearly. I have given intentionally in Fig. 2 the optimum condition of the intestine of rats fed on our ordinary laboratory diet. Occasionally one finds in rats kept on this diet a much more atrophic condition, sometimes with extensive necrosis of the villi resembling the condition illustrated in Fig. 3. In a previous paper⁶ I have shown that animals from stocks kept on such a diet restricted in vitamin content, or "underfed with vitamins" as it was called, react much more rapidly to a vitamin-A deficiency: they will stop growing at once when vitamin A is withheld, and develop the typical eye lesion within eight to nine weeks, while animals from a vitamin-rich stock, kept in the same cage on the same diet, may continue to grow actively for several weeks, may not develop the eye lesion within six months, and at the end of that time have quite a normal appearance, although eventually they decline in health. The difference in the condition of the intestine in the two stocks explains this apparently paradoxical phenomenon; atrophy of the intestinal mucous membrane will, of course, proceed much more rapidly in an animal in which the full development of the intestinal mucous membrane has never been attained, and may even be definitely atrophic owing to having been kept since birth on a vitamin-restricted diet. The fact that rats apparently normal, in the sense that they do not show any macroscopic obvious sign of disease, may have definite pathological lesions in the intestine introduces a fallacy into vitamin experiments which has not received consideration. This fallacy can be guarded against, although not entirely eliminated, by using for such experiments only animals bred in the laboratory and kept on a diet of a known and constant vitamin content. In order to illustrate graphically the extent to which the general condition of an apparently normal rat as expressed in its weight curve is dependent, not merely on the presence of vitamins, but on the presence of abundant vitamins, I give curves (Fig. 6) showing the typical behaviour of four normal rats belonging to two litters of practically the same age. Rats No. 511 and 515 belong to litter A, which had been kept since birth on our ordinary laboratory diet (bread, water, maize, and rice); rats 523 and 518 belonged to another litter of the same age and kept on the same diet supplemented by marmite and cod-liver oil. When three months' old, one rat of the vitamin-underfed litter A was placed on the vitamin-rich diet (No. 515) and one rat of the vitamin-rich litter B was placed on the ordinary laboratory diet and thus subjected to vitamin-underfeeding (No. 518). The curves readily explain themselves in the light of our observation that vitamins have a stimulating action on intestinal functions.

It should be noted that the rats from the "vitamin underfed" litter are in appearance perfectly healthy looking normal animals; they are, in fact, our usual laboratory stock. They only differ in appearance from rats of the same age, kept on a vitamin-rich diet, by being smaller. If in the present experiment the exact age of rats Nos. 511 and 515 had not been known, they might have been taken for younger animals which had been kept on a vitamin-rich diet. The experiment shows how even such healthy animals may benefit by increasing the supply of vitamins. The great susceptibility of the intestinal mucosa to

the supply of vitamins, especially the fat-soluble vitamin A, and the occasional occurrence of atrophic and sometimes of definite pathological changes on a natural diet which enables the animal to lead an otherwise normal vegetative and reproductive life has an important bearing on problems of general importance. For since this diet, so far as its restricted vitamin content is concerned, is not unlike that on

FIG. 6.

Weight curves of four rats of the same age belonging to two litters. Rats Nos. 511 and 515 had been kept on the laboratory diet since birth; rats Nos. 518 and 523 had been kept on the laboratory diet supplemented with cod-liver oil and marmite. The curves illustrate the stunted growth of healthy rats produced by vitamin underfeeding, and the beneficial effect of the addition of vitamins even on such healthy rats. The condition of the intestine of two of the rats (Nos. 511 and 523) is represented in Figs. 1 and 2.

which large classes of civilised mankind live, this factor may account for numerous conditions of vague ill-health, stunted growth, and intestinal derangements and toxæmias for which there is at present no adequate explanation.

Vitamins as "Food Hormones."

If we review the foregoing statements concerning the mode of action of the two vitamins A and B which are essential for the normal life of the rat, we find that the absence of these vitamins interferes with the usual functions of the digestive tract. In the absence of vitamin B the normal assimilation of food is impaired owing to the atrophy of the lymphoid tissue. In the absence of vitamin A there is the obvious impediment due to the atrophic intestinal mucosa. This relationship is analogous to the relationship which exists between certain endocrine organs and specific tissues. Thus we get atrophy of the uterus when the ovary is removed, and atrophy of the testes when the pituitary is damaged or partially removed. From such facts the existence of a hormone with a specific stimulating action is postulated. The stimulation is in many cases only inferred from the occurrence of atrophic changes in the absence of these hormones. The observations with vitamins provide more conclusive evidence of the existence of a direct specific stimulating action. There is the rapidity with which the lymphoid tissue or the intestinal mucosa, as the case may be, recovers, when the appropriate vitamins are administered after a previous deficiency. Further, there is evidence that the organism recovers more rapidly from a lymphopenia induced by radiation when an abundant supply of vitamin B is administered. The most conclusive proof of the existence of a direct stimulating effect of vitamins on the intestinal activity of perfectly normal animals was given by us in a previous paper in which fat absorption was taken as a microchemically demonstrable criterion.

These observations, then, lead to the conception that these food-accessory substances, called vitamins, are "food-hormones"—that is to say, the different articles of food contain, in varying but always small

amounts, substances having a drug-like stimulating action on the digestive tract. And, further, the full functional activity of the digestive tract is dependent on an abundant and continued supply of these substances in the food, in the same way as the full functional activity of the uterus is dependent on a continued supply of the ovarian hormones. We can recognise in these food hormones from their specific mode of action two groups of substances—that group which stimulates the lymphoid tissues and is essential for its functional integrity, now known as the water-soluble vitamin B, and that which stimulates the intestinal mucous membrane and is necessary for its integrity, now known as the fat-soluble vitamin A. The latter has also directly or indirectly a stimulating effect on the formation of the blood platelets. We may notice, in passing, that this conception brings out a relationship between an organism and its environment which is interesting from an evolutionary point of view: the apparatus which is responsible for the absorption of food in a highly differentiated animal is itself dependent for its functional integrity upon the presence in the food itself of these hormone-like substances.

Therapeutic Applications.

In a previous paper the necessity of ensuring an abundant supply of vitamins in the food, especially of the young, was pointed out. It was shown that there is such a condition as "underfeeding with vitamins" which does not manifest itself by any obvious signs of disease, but which prevents the organism from attaining its full development and makes it more susceptible to dietetic disorders. The fact that the intestinal mucous membrane is less fully developed in such vitamin-underfed animals lends further support to this view.

But our observations suggest further that preparations such as cod-liver oil or yeast preparations, which are especially rich in these food hormones, represent drugs with definite actions which may be of considerable therapeutic value in conditions not necessarily due to vitamin deficiency or vitamin underfeeding. Certain forms of marasmus in infants, not due to deficiency of vitamins, are stated to yield rapidly to the administration of preparations rich in vitamins. Probably the primary lesion in these conditions is an imperfect development of the digestive tract.

Dr. William Hunter⁷ attributes great importance to lesions in the digestive tract in the aetiology of pernicious anæmia, and it is suggestive that we have repeatedly observed an anæmia to set in both in vitamin-A deficiency and after exposure to radium, where intestinal lesions occur. It is well known that the anæmia produced by exposure to radium is of a pernicious type. Dr. J. A. Murray has informed me that, in his experience as a pathologist to a lunatic asylum, he has frequently observed atrophic lesions in the intestine of patients suffering from melancholia. It seems possible that the administration of vitamin-rich preparations may be of use in such conditions.

Vitamins and Light.

Observations on the effect of light on the organism which we have carried out in collaboration with Dr. A. H. Drew have shown that light acts as a stimulus to the production of blood platelets. We intend to publish the results in detail elsewhere. Here I shall deal only with that aspect of the subject which has a bearing on the action of the fat-soluble vitamin A. Rats kept in the dark since birth show a considerable reduction in the number of platelets. They exhibit no gross intestinal lesions, their growth and appearance is normal when compared with rats kept in daylight on the same diet, and they do not show the characteristic infections (xerophthalmia, septic lymph glands) appearing in fat-soluble vitamin deficiency. But when exposed to such a deficiency they develop these lesions sooner than rats kept in daylight. Conversely, when rats are kept on a diet free from vitamin A the application of light delays the fall in

the number of platelets. It also delays the general decline of the animal and the onset of xerophthalmia, although it cannot altogether prevent them. The apparently paradoxical fact that light can to a certain extent counteract a dietetic deficiency can thus be readily explained on morphological grounds; vitamin-A deficiency produces a twofold lesion—a lesion in the intestinal mucosa and a diminution in the number of platelets. Light acts as a stimulus to the formation of platelets, and thus strengthens one of the defensive mechanisms against bacterial invasion from the intestine.

Summary.

From observations on the pathological lesions induced by vitamin deficiencies a mass of evidence has gradually accumulated which points to the digestive tract as the key to the problem of the mode of action of these food accessory substances. The functional integrity of the digestive tract is dependent on the presence in the food of certain substances with specific drug-like actions, very much in the same way as the functional integrity of the uterus is dependent on a hormone produced by the ovary. These accessory food substances may therefore be looked upon as "food hormones." Two groups with different specific actions can at present be distinguished—one group (now called the water-soluble vitamin B) has a specific stimulating effect on lymphoid tissue. The other group (now called the fat-soluble vitamin A) has a specific stimulating effect on the intestinal mucous membrane, and also directly or indirectly on the formation of blood platelets. These specific effects afford an adequate explanation of the general changes produced in an animal by restricting or completely withholding vitamins from the food.

An interesting relationship is thus brought out between an animal and its environment; the food itself contains specific substances on which the integrity of the apparatus responsible for the digestion and absorption of food depends. The therapeutic applications following from this conception are briefly discussed.

Addendum.—The view that vitamins have a drug-like action on the digestive tract which may be used for therapeutic purposes has received confirmation from some recent observations of Murlin and Mattill "on the laxative action of yeast,"⁸ which have appeared since our paper was sent in for publication. Murlin and Mattill have tested some old clinical observations of a number of French clinicians,⁹ who found brewer's yeast to be a valuable remedy in intestinal disorders. Some recommend it as a laxative, others find it an important remedial agent in enteritis, typhoid, and various types of diarrhoea, including diarrhoea in infants. The carefully controlled investigations of Murlin and Mattill show that fresh yeast has a distinct laxative effect in normal men. They also find a prolonged increased excretion of uric acid in the urine, and evidence of diminished intestinal putrefaction. Murlin and Mattill do not refer these effects to the presence in the yeast of water-soluble vitamin B, but are inclined to attribute the effect to the nucleins of yeast. These effects on man are in complete agreement with our observations in rats of the effect of vitamin B, given in the form of a commercial preparation of autolysed yeast. The fact that yeast has a laxative effect in normal people does not exclude, as Murlin thinks, the possibility that yeast in virtue of its vitamin-B content might have a remedial effect in certain types of enteritis. His results read in the light of our conclusions make further clinical observations desirable, preferably where autolysed yeast is used.

THE TREATMENT OF AURICULAR FIBRILLATION BY QUINIDINE SULPHATE.

By J. G. EMANUEL, M.D., B.Sc., F.R.C.P. LOND.,
HONORARY PHYSICIAN, QUEEN'S HOSPITAL, AND CONSULTING
PHYSICIAN, HOSPITAL FOR SICK CHILDREN, BIRMINGHAM.

AURICULAR fibrillation is a functional disorder of rhythm arising in a heart that was previously contracting with an orderly regular rhythm known as sinus rhythm. Normally the healthy adult heart contracts some 70 to 80 times per minute, in response to impulses generated and discharged at a regular rate. These impulses arise in the pace-maker of the heart—the sino-auricular node, a small collection of fibrous tissue in which are numerous specialised muscle fibres, some nerve cells, and some nerve fibres; it is situated in the right auricle, near the opening of the superior vena cava, and the vagal and sympathetic nerve-trunks are connected with it. When auricular fibrillation occurs, the function of the pace-maker remains in abeyance, and its rôle is taken up by the muscle fibres of the auricular walls. These fibres have hitherto only been accustomed to conduct impulses from the pace-maker to the ventricles. With the onset of auricular fibrillation they assume a new function, and generate some 400, 500, or 600 impulses per minute.

In auricular fibrillation, then, these impulses replace the 70 to 80 impulses formerly generated by the specialised fibres of the pace-maker; they are conveyed by the auriculo-ventricular bundle to the ventricles, which cannot respond to so large a number of impulses, but do respond to many of them, albeit in a disorderly fashion; thus the ventricular contractions follow one another at irregular periods and are of varying force. Consequently when auricular fibrillation occurs, a pulse previously regular in force and rhythm becomes totally irregular in both respects—becomes, in fact, the characteristic and generally rapid pulse of auricular fibrillation. This change of pulse coincides with virtual paralysis of the auricle. Sir James Mackenzie predicted this paralysis in 1902, although in 1907–08 he changed his view, arguing that when this "pulsus irregularis perpetuus" occurred auricles and ventricles contracted synchronously, and he called the irregular rhythm nodal rhythm. During the years 1909–11 Sir Thomas Lewis proved that when this type of pulse occurred, the auricles were in a state of passive distension and their walls exhibited the fine movements known as fibrillation, a condition readily produced experimentally in animals by faradisation of the auricles.

Auricular fibrillation does not arise unless there is some pathological condition of the myocardium; it may accompany valvular disease of the heart, or myocardial degeneration without disease of the valves. It occurs in rheumatic and non-rheumatic hearts, in both sexes and at all ages, though it is extremely rare in childhood. Its presence can generally be inferred by the stethoscope alone, but more reliable information can be obtained from a sphygmographic tracing of the radial artery, while a simultaneous record of the radial artery and jugular vein by means of the polygraph will yield a still more certain diagnosis. The electro-cardiograph alone furnishes absolute proof of the new rhythm.

Why Does Auricular Fibrillation Call for Treatment?

Sooner or later, and generally sooner, auricular fibrillation leads to cardiac failure, and for this reason calls for treatment. Little more than 20 years ago the view held was that when cardiac failure set in the pulse frequently became irregular. To-day we realise that the irregular rhythm of the pulse, or rather the irregular action of the heart, of which the pulse is the indicator, causes the heart to fail. Sir Thomas Lewis points out that in 60 to 70 per cent. of the cases of cardiac failure in the wards of general hospitals auricular fibrillation is present; and I would add that the vast majority of these cases would not be in-patients had not auricular fibrillation occurred. Out of 30 heart cases with auricular fibrillation under my care at the Queen's Hospital, Birmingham, during the past 18 months, more than half had no symptom of any cardiac disease whatever until the onset of auricular fibrillation. In the remaining cases shortness of breath on exertion or palpitation preceded the onset of auricular fibrillation, but as a rule were not sufficient to interfere with an active life. With the onset of auricular fibrillation more or less chronic invalidism followed. The following cases are typical.

CASE 1.—A motor engineer, aged 29, was admitted into hospital on Nov. 7th, 1922, with a hypertrophied heart (the apex beat was in the fifth space, 4 inches from the mid-sternal line, the cardiac impulse was strongly heaving), and the physical signs of mitral stenosis with auricular fibrillation. He had an attack of rheumatic fever at 9 years of age, and was in bed for two months. Had lived a normal life since that time, and had carried on his occupation uninterruptedly until five weeks before admission, although there was evidence of some restriction in the response of his heart to effort, in consequence of which he had given up cycling. Presumably auricular fibrillation occurred five weeks before admission, when, on his way to work, going uphill at his ordinary pace, he was suddenly seized with violent palpitations and a sense of suffocation. He rested for some minutes, and then managed to reach the factory in a state of great distress. Immediately after his arrival he was taken home in an ambulance, and remained in bed for four weeks. A week later he was admitted into hospital, and 20 days after admission sinus rhythm was restored by five doses of 6 gr. quinidine sulphate.

CASE 2.—A blacksmith, aged 62, was admitted into hospital on Nov. 3rd, 1922, with a large heart (the cardiac impulse was in the fifth space, 5½ inches from the mid-sternal line), and auricular fibrillation. There was no evidence of valvular disease; the myocardial change was probably of rheumatic origin, for about 12 years ago he had been laid up in bed for two or three weeks with what was probably an attack of rheumatic fever. He had, however, never known breathlessness until one day in July, 1922, when walking uphill, he suddenly became breathless, and realised some change in the heart's action. His doctor sent him to bed the same day, and he remained there for two months. With this rest breathlessness improved up to a point, but on getting up oedema of the legs and scrotum appeared, and he was only able to walk a very short distance on the level. In this state he was admitted to hospital, and three weeks later sinus rhythm was restored, after two doses of 6 gr. quinidine sulphate.

Here there were no symptoms of any cardiac inefficiency until auricular fibrillation occurred; in the first case there was some evidence of cardiac inadequacy over a period of years, but no serious cardiac failure until auricular fibrillation set in.

The Two Forms of Auricular Fibrillation.

Auricular fibrillation is met with in two forms: (1) A temporary affection, occurring in paroxysms lasting a number of hours, days, or weeks, and forming one of the varieties of paroxysmal tachycardia. (2) A chronic affection which is generally permanent—I say generally permanent, because even where fibrillation has persisted for some months it may cease spontaneously, and the cardiac contractions may again come under the control of the pace-maker. Auricular fibrillation is only a functional disorder; there is no a priori reason why sinus rhythm should not be re-established however long the auricles have been fibrillating. Never-

theless the rule is, that once established, the new rhythm is permanent and exceptions are rare.

Attacks of paroxysmal tachycardia due to paroxysms of auricular fibrillation either terminate spontaneously, or can be terminated by digitalis, and with the cessation of the paroxysm the normal sinus rhythm is re-established, for this is the meaning of the term "paroxysmal tachycardia." The administration of quinidine sulphate in these cases, for the purpose of restoring sinus rhythm, need not therefore be discussed. It is reported, however, that the drug has been used with advantage for controlling the frequency of the attacks in paroxysmal auricular fibrillation.¹

Chronic or permanent auricular fibrillation is met with in three classes of cases, which may be described as (1) temporarily disabled; (2) walking cases; (3) permanently disabled.

(1) *Temporarily Disabled*.—Under this heading I group the majority of cases of auricular fibrillation as seen in practice. The patient is compelled to be in bed; dyspnoea is severe, and generally amounts to orthopnoea; there is oedema, cyanosis, fullness of the jugular veins, albuminuria, enlarged and congested liver, and possibly evidence of congestion and oedema of the lung bases. The pulse is rapid, 120–150 per minute, and irregular in force and rhythm; a false impression of the cardiac contractions is frequently given, as many of the beats fail to affect the radial artery at the wrist. Under treatment, rest in bed and digitalis, these cases do well and pass into Class 2.

(2) *Walking Cases*.—These patients, in spite of auricular fibrillation, can lead active and often strenuous lives, either without digitalis, or with the help of an occasional course of digitalis, or by taking small doses of the drug regularly. They may live in comfort for years, but from time to time are liable to lapse into Class 1, from which rest in bed and a course of digitalis will restore them to Class 2. For the most part Class 2 are the convalescents of Class 1, although occasionally patients are found belonging to this class who have never suffered from a severe attack of cardiac failure.

(3) *Permanently Disabled*.—These are cases of auricular fibrillation with symptoms similar in every way to those of Class 1, but in whom, though the pulse is slow in rate (a bradycardia of 30 to 40 per minute, or a normal rate of 60–70 or 80 per minute), no improvement follows any form of treatment; their course is progressively downwards. The slow rate may be the result of digitalis therapy, or it may occur independently of drugs—i.e., the nodal bradycardia of Sir James Mackenzie. The characteristic feature of these cases is that although the pulse-rate is within normal limits or abnormally slow (bradycardia), the dyspnoea, dropsy, and cyanosis persist and gradually increase, in spite of all treatment. The prognosis is hopeless. The myocardium is worn out. Here auricular fibrillation is not the cause of cardiac failure, but an accidental concomitant, or possibly a result of that failure, a means of setting free the worn-out ventricle from the control of the pace-maker. There is no question of restoring sinus rhythm by means of quinidine; even if the rhythm were restored, the patient would be no better off. The rule is for auricular fibrillation to be accompanied by a rapid pulse-rate of 140–150 per minute; as Sir Thomas Lewis has pointed out, the pulse tends to double its rate. Where auricular fibrillation coexists with a pulse of normal or subnormal rate (bradycardia) the explanation is probably that the myocardial degeneration responsible for the altered rhythm is also responsible for affecting some of the junctional fibres between auricle and ventricle; in other words, degeneration of the myocardium has caused a certain degree of auriculo-ventricular heart-block. What degenerative changes have effected in the course of months or years in Class 3, digitalis can effect in the course of hours or days in Class 1.

¹ Parkinson and Nicholl: THE LANCET, 1922, ii., 1267.

Treatment of Auricular Fibrillation.

A great deal of harm will accrue to sufferers from auricular fibrillation if the value of digitalis is lost sight of in the quest of new drugs like quinidine. Digitalis has a specific action on auricular fibrillation and cannot be replaced. It is difficult to say whether in the order of nature digitalis or auricular fibrillation was first evolved, but it is highly probable that digitalis would never have been recognised as a potent drug for the removal of dropsy had not auricular fibrillation been the cause of the dropsy. Quinidine may supplement digitalis, but will never supplant it. The two drugs have different functions and must be used accordingly. The indication for digitalis in cases of cardiac failure is auricular fibrillation with a ventricular rate above normal. If given in sufficient amount, digitalis will not fail to lower the rate from 150-160 per minute to a rate of 60-70-80 per minute, and with this drop in the pulse-rate, in practically all cases, the dyspnoea, dropsy, and cyanosis, &c., will gradually improve. In a very small percentage of cases (Class 3) no improvement follows.

Digitalis appears to act on the junctional fibres between auricle and ventricle, for the electro-cardiograph shows that the fibrillations of the auricle are undisturbed though the ventricular rate is lowered. The Class 1 patient having been brought into Class 2—i.e., so far restored as to be able to walk a short distance on the level—is now, and not till now, ready for quinidine administration; the latter can convert the abnormal rhythm to the normal sinus rhythm. Digitalis, however much it may improve the patient's condition, will not produce this result (Figs. 1 and 2).

FIG. 1.

Sphygmograph of a male aged 62. Myocardial degeneration with auricular fibrillation. 1. Before treatment: rate 99, rhythm irregular. 2. After digitalis: rate 66, rhythm irregular. 3. After quinidine: rate 78, rhythm regular.

On the other hand, quinidine sulphate must not be used to restore cases with cardiac failure, this is the rôle of digitalis; quinidine will only restore rhythm. But if there are no symptoms of cardiac failure, why give quinidine or any other drug? Because the patient is better with a normal rhythm than with auricular fibrillation, for the cardiac efficiency is greater. It is not easy to give scientific proof of such a statement, but there are cogent reasons for believing it to be true, and personally I have no doubt about it.

Statements of Patients.

(1) Patients state that they are more comfortable, feel better, and can do more after restoration of the sinus rhythm.

CASE 3.—A married woman, aged 46, had symptoms of breathlessness on exertion and a winter cough since childhood. She had a large heart, obscured by an emphysematous lung. Transverse diameter 7 inches. No evidence of valvular disease. She had had three attacks of rheumatic fever, at 12, 25, and 33 years of age. Her cardiac inefficiency was not great, for, in addition to her housework, she was able to work regularly during the war "on shells." In September, 1920, she caught cold and had "a dry cough which pulled her to pieces," and probably at this time auricular fibrillation occurred, for she then became invalided. She was admitted to Queen's Hospital three times

between December, 1920, and December, 1921, with marked cyanosis, dropsy, and auricular fibrillation with rapid pulse. Each time she left hospital freed from all distressing symptoms after a course of digitalis, but on each occasion the improvement was temporary. On Jan. 6th, 1922, she was admitted for a fourth time, again cyanosed and oedematous, and with the irregular pulse of auricular fibrillation, which varied in rate from 120 to 170 per minute.

FIG. 2.

Before Treatment
Rate 132 per minute

Aft. Digitalis
Rate 52 per minute

Aft. Quinidine Sulphate
Rate 60 per minute

Electro-cardiograms of female, aged 28, with mitral stenosis of rheumatic origin, and auricular fibrillation. 1. Before treatment. 2. After digitalis. 3. After quinidine.

Note.—Although digitalis has slowed the ventricle from 132 to 52 beats per minute, fibrillation of the auricle is still present. After quinidine, sinus rhythm is restored.

The pulse was brought down to 70-80 per minute by digitalis, and on the 10th, after 54 gr. of quinidine administered in nine doses in 16 hours, sinus rhythm was restored. Three weeks later she left hospital, and remained well and in active work until Jan. 31st, 1923, when auricular fibrillation recurred, but only after an interval of 12 months. This time sinus rhythm was re-established after five doses of quinidine taken in two days.

In this case the value of quinidine is evident, for during the year 1921 the patient was in and out of hospital three times and more or less of an invalid when at home. During the year 1922, after restoration of the sinus rhythm, she led the active life of a housewife, and was not taking any drugs.

(2) Patients successfully treated with quinidine, in whom auricular fibrillation has recurred, return to hospital for a further course of quinidine. In some cases patients themselves treat recurrent attacks successfully at home, having learnt the details of treatment in hospital.

(3) The volume of the pulse is greater with a sinus rhythm than when auricular fibrillation is present. Sphygmographic tracings show a conspicuous difference between the small volume of the pulse tracings of auricular fibrillation and that of sinus rhythm. In taking pulse tracings before and after quinidine administration it is often difficult to obtain a satisfactory tracing during the stage of auricular fibrillation, but this becomes quite easy when sinus rhythm is established; this change in volume of the pulse is well appreciated by the nursing staff in charge of my cases at Queen's Hospital. They know when the pulse becomes regular in a doubtful case, rather by the increased volume than by actual regularity of rhythm, for when sinus rhythm has been restored its regularity is not uncommonly obscured by occasional extrasystoles. This increase in volume has a practical bearing on the watching of cases under quinidine treatment; in many cases during the passage from auricular fibrillation to sinus rhythm there is a period in which auricular flutter replaces auricular fibrillation, and when this occurs the pulse is generally regular, albeit often rapid.

This increase in the volume of the pulse is due to restoration of function of the auricle. During

fibrillation the auricle is virtually paralysed, during sinus rhythm its coördinate contraction helps in the final stage of the filling of the ventricle. Hence in sinus rhythm the ventricle is better filled with blood than in auricular fibrillation. Possibly another factor in this increase of volume is that in auricular fibrillation all the ventricular fibres do not participate in every ventricular contraction, while in sinus rhythm they do. As Sir James Mackenzie has pointed out, when the stimulus arises in the muscle fibres of the auricle instead of in the sino-auricular node, the ventricular systole is often partial and ineffective, and so the volume of the pulse is small.

(4) The greatest gain to the patient when auricular fibrillation is restored to sinus rhythm is stability of the pulse. In auricular fibrillation a walk of 50 yards on the level may increase the pulse-rate by 20 to 50 beats per minute, whereas with sinus rhythm the same amount of exercise will not increase the same patient's pulse-rate at all.

The accompanying chart (Fig. 3) shows the pulse of a female, aged 20, suffering from mitral stenosis of rheumatic origin, and illustrates the instability of the pulse when auricular fibrillation is present, A—F, compared with the stability of the pulse when sinus

must be given in full doses, much greater than those frequently adopted.

The Limitations of Quinidine.

(1) Quinidine must be regarded as a drug merely for altering an abnormal rhythm, and not for treating symptoms of cardiac failure.

(2) While quinidine is capable of restoring sinus rhythm in a case of auricular fibrillation, it will not prevent its recurrence. Its utility in a given case, therefore, entirely depends upon the liability for auricular fibrillation to recur; this liability cannot at present be estimated, for the exciting cause of auricular fibrillation is unknown, as is that of the occasional extrasystole giving rise to the so-called intermittent pulse.

The predisposing cause of fibrillation is well recognised as some degenerative change in the muscular fibres of the auricle; but there must be some immediate excitant which conceivably reaches the auricle through the nervous system, for its action is instantaneous. This indeterminate excitant factor constitutes one of the limitations of quinidine, for while this drug can restore sinus rhythm, it cannot prevent the recurrence of fibrillation.

FIG. 3.

A—B=Pulse-rate on admission. B—C=Fall of pulse-rate under digitalis. C—D=Rise of pulse-rate under unsuccessful course of quinidine. D—E=Rapid and variable pulse, all drugs omitted. E—F=Fall of pulse-rate under digitalis. F—G=Sinus rhythm restored by a two days' course of quinidine and immediately followed by a steady pulse-rate, although patient was taking no drugs and was walking about. A—F=Auricular fibrillation present, and patient was confined to bed. At B and again at E administration commenced of tabloids of digitalin (cryst.) 1/250 gr.; at C and again at F, doses of quinidine sulphate, 6 gr.

rhythm is present, F—G. The chart covers a period of 10½ weeks.

In September, 1921, I began treating cases of auricular fibrillation with quinidine sulphate. Since this date I have treated 30 cases, and have failed to restore sinus rhythm in two; if only suitable cases be selected, I believe that quinidine will *always* restore the sinus rhythm. I account for the two failures by having included what I now consider to be two cases unsuitable for treatment.

Selection of Cases.

In selecting cases for quinidine therapy, I have based my selection entirely on the response of the patient to digitalis. Given a case suffering from cardiac failure with auricular fibrillation, the patient is treated in the routine manner by rest and digitalis, with purgatives and blood-letting if necessary. If—as in the vast majority of cases—the patient responds well to treatment, we may deduce that auricular fibrillation is the cause of the cardiac failure; in these cases quinidine should be used, for if we can change the rhythm we cure the heart failure. If, however, there is no satisfactory improvement in the patient's state, in spite of the lowering of the ventricular rate to within normal limits, then cardiac failure is due not to auricular fibrillation, but to a worn-out heart muscle. This only occurs in a small number of cases, and in these quinidine should not be used. The restoration of sinus rhythm is not called for—it may even be prejudicial. Before assuming, however, that a case of auricular fibrillation will not respond to digitalis, the drug

Cases vary greatly in the length of time that sinus rhythm is maintained after quinidine therapy. In some of my cases rhythm has remained regular, and cardiac efficiency at a relatively high level, for 12 months and over; but other cases have relapsed while still in hospital, in the course of a few days. I now make a practice of restoring such cases three or four times; if a further relapse occurs I recommend the patient to make himself familiar with the use of digitalis, on which he may have to depend for the rest of his life, taking the drug as occasion demands.

Dangers of the Drug.

I have had no fatalities. Minor symptoms, such as headache, nausea, vomiting, giddiness, are not infrequently complained of. Serious symptoms appeared in three cases: in one a temporary hemiplegia, possibly the result of embolism; in another epileptiform attacks at noon, 5.30 P.M., and 7 P.M. on the same day; in a third an epileptiform seizure occurred with cessation of respiration and failure of the pulse. The patient was restored by artificial respiration. A second less severe seizure occurred three hours later on the same day. All three patients completely recovered and were none the worse 24 hours afterwards. In the first two cases these alarming symptoms occurred whilst the auricle was fibrillating, but in the third case sinus rhythm had already been established for 22 hours.

All had been treated with small doses of the drug; in no cases where large doses (48 or even 60 gr. per day) had been given were there any serious symptoms.

Dosage.

I have found no reason for departing from the original dose recommended by Frey—viz., 0.4 g. (approximately 6 gr.). It is given in capsules by the mouth. With regard to frequency of dosage, after trying many variations, I have been led to regard the following as the safest and most successful. One dose is given the first day, two the second, three the third, and so on till a maximum of ten doses may be reached. This large number, however, is rarely necessary, the majority of the cases being restored on the second, third, or fourth day. The dose is repeated every two hours, and I find it convenient at hospital to give the initial dose at 5 A.M., so that on the fourth day of administration, for example, the patient has a capsule at 5, 7, 9, and 11 A.M.

The pulse is recorded hourly, and if necessary the nurse is instructed to estimate the ventricular rate from the apex beat. She records not only the rate, but also the rhythm, adding the word "regular" or "irregular" to the pulse chart. The quinidine is discontinued as soon as a regular rhythm is noted, and the patient, who has been kept in bed during the administration of the drug, is allowed up on the following day. Electro-cardiograms are taken as controls as often as may be found necessary. No rhythm is accepted as sinus rhythm without confirmation by the electro-cardiograph. I have found no advantage in persevering with small doses of quinidine after sinus rhythm has once been established.

A point of importance is that the intervals between successive doses of quinidine should be short, for quinidine seems to be rapidly eliminated. I have succeeded with small quantities of the drug given at two-hourly intervals in cases unaffected by much larger quantities given at six or even four-hourly intervals. I have found it undesirable to give digitalis and quinidine at the same time. The secret of success depends, in my opinion, on not being in a hurry to give quinidine. Rest in bed and digitalis must first bring about such improvement in the degree of heart failure that no further benefit can be obtained from digitalis. As a rule, the patient will be able to walk for half an hour on the level without discomfort. When this stage has been reached, two or three days should be allowed to elapse without digitalis, and then a course of quinidine may be commenced.

In conclusion, I may state that for the treatment of cardiac failure with auricular fibrillation, digitalis is a specific remedy and quinidine an invaluable coadjutor.

BOGNOR WAR MEMORIAL HOSPITAL.—The premises in Chichester-road, Bognor, which thanks to the generosity of Mr. James Fleming, of Aldwick Grange, were opened for patients in July, 1919, and were adopted by the town as the war memorial, have already outgrown the demands made upon them. At the annual meeting on May 14th an extension fund was opened with the object of making provision for the erection of new buildings which would be more suitable for the purposes of a hospital and which would contain accommodation for paying patients. In-patients during the year ended March 31st numbered 148, and out-patients 1819. The income was £1750 8s. 10d., and the expenditure £1444 16s. 6½d., showing an excess of income over expenditure of £305 12s. 3½d.

CONTROL OF VENEREAL DISEASES: RESOLUTIONS OF THE SCOTTISH COMMITTEE.—The May issue of *Health and Empire* has printed an account of the conference held at Glasgow on March 8th, when representatives of local authorities met members of the Scottish Committee of the National Council for Combating Venereal Diseases. Three important resolutions were passed at this meeting:—

That in the opinion of this conference the present law and machinery are inadequate to secure the proper control and treatment of venereal diseases.

That in order to secure adequate control of venereal diseases (both acquired and congenital) it is essential that a system of notification should be introduced.

That it is essential every person suffering from V.D. should be required by law to place himself or herself under treatment by a qualified medical practitioner and to continue under such treatment until pronounced free of infection.

Of these resolutions the first and second were carried unanimously and the third with two dissentients.

NOTES ON

ONE HUNDRED HUMAN FŒTUSES.

BY M. F. LUCAS KEENE, M.B., B.S. LOND.,
UNIVERSITY READER IN ANATOMY, LONDON (ROYAL FREE
HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN;

AND

EVELYN E. HEWER, D.Sc. LOND.,
LECTURER IN HISTOLOGY AT THE ABOVE SCHOOL.

FOR the past four years we have been engaged in an investigation of the stillborn human foetus, one of us (M. F. L. K.) concentrating upon the relations between certain foetal abnormalities and the ductless glands, and the other (E. E. H.) upon the possible part played by the ductless glands in stillbirth. Full analyses of our cases (already about 250 in number) are not yet available, but we were much interested to note that Eardley Holland¹ has found that in 167 fresh (non-macerated) foetuses of viable age, 81—i.e., 48 per cent.—had sustained tears of the tentorium cerebelli. This observation differs so widely from our own findings that the latter seem definitely worth recording.

1. Tentorial Tears and Subdural Hæmorrhage.

For the purpose of this report we have taken, without any selection, the last 100 fresh foetuses of viable age received, and divided them into full-time (67) and premature (33) births. With regard to tears of the falx cerebri, it is not uncommon to find fenestrations of this fold of dura mater in dissecting-room subjects; possibly these were actually produced at birth. We found that the dural folds varied very much with regard to fragility in different foetuses, the greatest care being necessary in some cases in examination of this region; but in one case (not included in the 100 under discussion) there had been considerable subdural hæmorrhage, probably from the vein of Galen, yet the dura mater was intact, and further, it was found that the foetus, weighing 6½ lb., could be suspended for a short time by its falx cerebri without any tears appearing. We ourselves have carried out almost every post-mortem examination and tedious as this method may be, and cramping as regards the amount of material that can be dealt with, we feel that it has its merits in that the personal factor in observation is eliminated.

(a) *Full-time Foetuses.*—Of these 67 foetuses, only five—i.e., 7.5 per cent.—showed tentorial tears, and three of these were accompanied by subdural hæmorrhage; in addition, seven had subdural hæmorrhage without any evidence of tentorial tears. Table I, giving the detailed analysis of these 12 cases, brings out the following interesting points: (1) Six of the mothers were primiparæ, having an average age of 31.3, the average age of the 12 mothers is 32.4 (2) seven of the 12 cases were district cases, five of these being spontaneous deliveries; (3) seven foetuses were female, five male.

Taking the history of labour, which would be expected to have some relation to the incidence of tears and hæmorrhages, the following classification is found:—

Spontaneous (6 cases).	1 Tentorial tear and hæmorrhage (f.).
	1 Tentorial tear only (m.).
	4 Hæmorrhage only (2 m.).
Instrumental or manipulation (6 cases).	2 Tentorial tear and hæmorrhage (1 m.).
	1 Tentorial tear only (f.).
	3 Hæmorrhage only (1 m.).

(b) *Premature Foetuses.*—Of these 33 foetuses, three—i.e., 9 per cent.—showed tentorial tears accompanied by subdural hæmorrhage, and in addition four had subdural hæmorrhage without any tears.

Table II. gives the further analysis of these seven cases, and brings out the following points: (1) Three

2155	F.	E.S.	1	21	Placenta prævia, leg brought down.	+	+	Lived 2 hrs.	31

D. = district; R.F.H. = Royal Free Hospital; E.S. = Endsleigh-street; P. = private.
M. = multipara; P.P.H. = post-partum hæmorrhage; R.O.P. = right occipito-posterior.

of the mothers were primiparæ, with an average age of 28.2 years; (2) six cases were from hospital sources, and one private; (3) Six fœtuses were female, one male.

The history of labour, classified as for the full-time fœtuses, is as follows:—

Spontaneous (2 cases).	1 Tentorial tear and hæmorrhage (hydrocephalus, f.).
	1 Hæmorrhage only (f.).
Manipulation (5 cases).	2 Tentorial tear and hæmorrhage (f.).
	3 Hæmorrhage only, one slight (1 m.).

2. Further Observations.

(a) *On the 67 Full-time Fœtuses.*—We thought it interesting to note the number of fœtuses delivered by forceps or by manipulation which did not show either tentorial tears or subdural hæmorrhage. Of the 67 fœtuses, these numbered 21—i.e., 31.3 per cent.; 16 of the 21 mothers were in-patients, 11 cases being first pregnancies. The average age of the mothers was 31.1 years; 18 of the 21 fœtuses were male. From the histories these were all cases of difficult labour, mostly treated in hospital; the fact that they show neither tentorial tears nor hæmorrhages is significant, especially when compared with the six cases (five of them from "district") of spontaneous delivery which did show such lesions. The total number of non-spontaneous deliveries among these 67 cases is 31; the 21 cases without tears or hæmorrhages just quoted, the six cases with tears or hæmorrhage, and four craniotomy cases.

(b) *On the 100 Cases.*—With regard to sex, although among these 100 fœtuses the males were not very greatly in excess of the females (58 male, 42 female), yet we found 23 males and 16 females among the 39 non-spontaneous deliveries.

Non-Spontaneous Deliveries.

	Male.	Female.	Total.
Full time ..	20 + 1 C.	7 + 3 C.	31
Premature ..	2	6	8

C. = craniotomy.

With regard to source, the 100 cases were obtained as follows:—

Gynæcological and Obstetrical Unit—	
(a) Royal Free Hospital ..	25
(b) Endsleigh-street ..	32
(c) District ..	24
Lambeth Infirmary ..	14
Thames Inn Hospital ..	4
Private ..	1

Seventy-five of the cases, therefore, were hospital in-patients.

Summary.

Taking the full-time and premature fœtuses together, we obtain the following figures:—

	Percentage.
1. Tentorial tears with subdural hæmorrhage ..	6
2. Tentorial tears alone ..	2
(i.e., tentorial tears, 8 per cent.)	
3. Subdural hæmorrhage only ..	11

These figures are strikingly lower than those obtained by Eardley Holland; we think it probable that neither figure represents the true average, and that this discrepancy is due at least in part to the fact that a sufficient number of cases has not yet been published. No doubt the actual treatment that the patient receives is a factor to be taken into account, and for this reason we have given above the sources of our 100 cases. In this connexion we note that of the 19 cases showing tear or hæmorrhage or both, seven were derived from "district," and five of these were full-time spontaneous deliveries.

It is also interesting to note that 9 (47 per cent.) of the mothers were primiparæ, and, further, that the average age of the mother was unusually high; from the figures we have quoted it appears that the first child of a mother of this class who is already about 30 years old fares badly. In our opinion, among these cases showing tentorial tears and subdural hæmorrhages death could be definitely ascribed to these lesions in one fœtus only, a case of hydrocephalus, which in addition showed extensive tears of the falx cerebri.

We would like to express our grateful thanks to Lady Barrett and to Prof. Louise McIlroy, who have supplied us with 75 of the 100 cases used in this report, and have also been extremely helpful in arranging that full histories are sent with the material. We also wish to thank Dr. A. L. Baly and Dr. J. W. Adams for the remaining fœtuses.

One of us (E. E. H.) is receiving a small grant from the Medical Research Council for research in antenatal pathology.

CROWBOROUGH COTTAGE HOSPITAL.—At the annual meeting on May 16th it was stated that additional rooms for the accommodation of the nursing staff are urgently needed and the committee recommend a special appeal for donations for this purpose. Mr. E. Maude, J.P., said there were certain sums in hand which could be made available for building purposes, but if they spent their invested capital they lost income. The governors, therefore, appeal earnestly for special donations. The balance-sheet showed that the receipts during the year amounted to £1293 11s. 10d., the expenditure showing a balance on the year of £38 14s. 7d.

Clinical and Laboratory Notes.

A CASE OF RECURRENT SUPPURATIVE FRONTAL SINUS DISEASE.¹

By E. WATSON-WILLIAMS, M.C., M.Ch. Camb.,
F.R.C.S. Edin.,

REGISTRAR, THROAT, NOSE, AND EAR DEPARTMENT, BRISTOL ROYAL
INFIRMARY; SURGEON FOR DISEASES OF EAR, NOSE,
AND THROAT, MINISTRY OF PENSIONS HOSPITAL,
BATH, AND SOUTHEAD HOSPITAL, BRISTOL.

THE following case is of interest, the patient recovering after a radical operation:—

A clerk, aged 26, in 1921, at Manchester, had the left frontal sinus operated on externally, with removal of front wall of sinus and superior margin of orbit. He had been attending the out-patient aural clinic for some months with slight nasal discharge and occasional headache. By anterior rhinoscopy very little was to be seen beyond a generally soppy condition high up on the left side. Symptoms were not troublesome. On Feb. 27th, 1922, after being in bed for some days with influenza, he had a great "feeling of fullness in the head." This became worse. On March 1st he came to the out-patient clinic very ill, with temperature 102° F., much pain, and an oedematous patch over the left eye 3 inches each way—a regular "puffy tumour." He was sent into hospital that night; the swelling was incised along the scar, but no pus was found. Next day the temperature was down, but the swelling extended from the hair margin on the left temple to the right outer angle of the orbit, rather more on right than on left, up to the hair line and down to orbital margins and bridge of nose. Mental condition was clear, a little slow.

Operation.—Ether was given and I operated. An incision was made from a point midway between the inner canthus of left eye and bridge of nose, along the lower edge of the eyebrow to outer angle; a second across the "spectacle line" of the nose. The flap of skin and scar tissue was turned up, and the frontal bone freely exposed. Creamy pus was found in four situations: (1) around the infundibulum; (2) in a small pit in the centre of what had been the posterior wall of the frontal sinus (the anterior wall had been previously removed); (3) in a high pocket, practically in centre of forehead—through this, infection appeared to be spreading to the right sinus; (4) in a deep lateral pocket, running directly back from external margin of sinus to a depth of 1 inch. Although the floor of the sinus had been previously removed, this pocket had a bony floor—i.e., it was in the sinus, not in the orbit. It was necessary to remove bone anteriorly in order to approach this. The whole of the sinus was cleaned out very carefully, the bone being lightly gouged in one or two suspicious places till healthy bone only was left. The floor of the "pocket" (4) was removed. The operation was then continued on right side, where infection had begun (see above) but was not general. A similar deep pocket was found at the external angle. The orbital margin was removed, also the inter-sinus crest and glabella, and the floor of the right sinus was taken away. The anterior ethmoidal cells on both sides were curetted out, a free opening into the nose being obtained. The whole of the exposed bone was rubbed with "bipp," excess being removed, and the wound closed; a small drain was left in above the inner canthus on either side.

Progress of Case.—His condition later was good. The temperature rose the next evening and the next to 100° F., but subsequently the course was afebrile. Healing was by first intention practically throughout the wound—a little oozing at the drains for a few days ceasing without trouble. Convalescence was rather protracted, and it was nearly six months before he returned to work. The condition now, a year after operation, is very good. There is no nasal discharge and no pain, except some aching in bad weather. The cosmetic result is fair—distinctly better than before. An interesting feature is the fact that diplopia, formerly so bad that he had spectacles with one eye obscured, is now only noticed for distant vision; for reading and up to about 10 yards, he has binocular vision.

The point of special interest in this case is the prolongation backwards at the outer angles of both sinuses; the use of "bipp" in the manner indicated gave a very satisfactory result.

¹ A case shown at a meeting of the B.M.A., Bristol Branch, January, 1923.

A NOTE ON DIRECT AND INDIRECT INGUINAL HERNIA ON THE SAME SIDE.

By HENRY GRIFFITHS, F.R.C.S. Edin.,
MEDICAL OFFICER, BASUTOLAND, SOUTH AFRICA.

THIS account of a case of direct and indirect inguinal hernia on the same side, which came under my care in June, 1921, appears to be similar to the case recorded by Dr. H. E. S. Stiven in THE LANCET of Oct. 7th, 1922.

The patient, an asthmatic European male, aged 56, consulted me in June, 1921, about attacks of pain in the region of the right groin, associated with vomiting. He had had several attacks, and suggested appendicitis as the cause. He stated that rest in the recumbent position usually relieved him in a few hours.

Examination revealed an "aldermanic" abdomen with a hard lump the size of a pigeon's egg situated just external to and slightly above the external ring. The man informed me that the pain when present seemed to be centred around this "lump" but that the lump had been present for years and had never previously troubled him in any way. I concluded that the swelling was an irreducible epiplocele and that the "attacks" were due to sudden increase in the contents of the sac. I advised him, in view of his general condition, that a truss would probably prevent any further trouble if he could stand its pressure over the lump. While waiting for the truss, and ignoring my advice, he proceeded one day to mount his horse, and was immediately seized with the same pain and vomited once. He went to bed immediately and took two morphia pills. I was called to see him some three hours afterwards and found him "much better." The lump was now slightly tender, but in view of the morphia taken I saw him again three hours later, ordering an enema to be given in the meantime. This produced a good result and I felt satisfied from his general condition that the new protrusion had returned inside the abdomen. The truss arrived shortly afterwards, but he could not wear it because of the pain produced in the "lump" by its pressure. He now begged to have the condition dealt with radically.

I operated a few days later. The "lump" proved to be a very old direct sac with a deep deposit of fat on its external surface; its neck was very rigid and it was empty. I excised the sac in the ordinary way and sutured its mouth. Further exploration of the cord now revealed to my surprise another very thin sac three-quarters of an inch in length coming out through the internal ring. This was also dealt with in the usual way. A satisfactory repair of the canal was impossible owing to the atrophy of the muscles, the conjoined tendon being practically non-existent, and I did not think the patient's age justified transplantation of fascia or any other procedure, feeling that a light truss would probably control any further tendency to bulge. He has been quite well since operation.

The case is, perhaps, most interesting from a diagnostic point of view. The presence of the indirect sac, the actual cause of his trouble, was quite unsuspected by me.

LEUKÆMIA IN THE MONKEY.

NOTE ON A SYNDROME IN A MONKEY (CYNOCEPHALUS SPHINX) SIMILAR TO THAT OF CHRONIC LYMPHATIC LEUKÆMIA IN MAN.

By ALDO C. MASSAGLIA, M.D.,
PROFESSOR OF PATHOLOGY AT THE STATE UNIVERSITY OF
NORTH DAKOTA.

IN the course of a series of attempts to transplant leukæmia, Banti's disease, or other diseases of unknown origin into the monkey, by means of transfusion of the blood or inoculation of an emulsion of some hæmatopoietic organs of patients suffering with these diseases, I found a syndrome which I believe is worth relating.

A monkey (*Cynocephalus sphinx*), age not exactly known, weighing 4400 g., remained under observation during November and December, 1922. Repeated examinations gave the following data: Anima apparently in good health; lymph-nodes, especially of inguinal region, very much swollen, firm, but not painful; spleen palpable, showing some tenderness

Blood examination (average of six examinations performed at different times) gave the following findings: Red cells, 4,000,000 per c.mm.; hæmoglobin, 55 per cent.; leucocytes, 36,000 per c.mm. Red cells appeared in good condition; very few normoblasts were found. The differential count of leucocytes showed: lymphocytes, 65 per cent.; large mononuclears and transitional forms, 17 per cent.; polymorphonuclear neutrophils, 18 per cent.

The monkey's apparent good health, the considerable enlargement of lymph-nodes, accompanied by slight enlargement of the spleen, the changes in the normal constitution of the blood—moderate diminution of red cells, with a diminution of the hæmoglobin proportionately more marked, leucocytosis due chiefly to an increase of the lymphocytes of the small type—all these data correspond to those which, in man, characterise the disease "chronic lymphatic leukaemia."

In horses, cattle, dogs, swine, and cats cases of leukaemia have been noted (Kitt¹), but I believe that this is the first case found in a monkey. And probably in the near future, if observations are made more frequently in animals which have the same, or almost the same, composition of the blood as man, we shall find in them several of those diseases which have been hitherto considered limited almost entirely to man.

A CASE OF

ACUTE POLIOENCEPHALITIS IN INFANCY, ASSOCIATED WITH GLYCOSURIA.

By T. PEARSE WILLIAMS, M.D., M.R.C.P. LOND.,
PHYSICIAN TO OUT-PATIENTS, PADDINGTON GREEN
CHILDREN'S HOSPITAL, LONDON.

THE following case is of sufficient interest to merit record:—

The patient, a male aged 2½ years, was first attended as an out-patient in June, 1921, when suffering from cough and loss of weight. Sugar and acetone were found in the urine. He was admitted to hospital, and beyond occasional vomiting and an evening rise of temperature to 100° F., no other abnormal signs were present. The weight was 24 lb., and sugar was still present in the urine. Improvement commenced ten days after admission, and after another ten days 25 g. of glucose were given by mouth, without the production of glycosuria. He was discharged from hospital shortly afterwards, no cause having been found for his original glycosuria.

Five weeks later he was again brought to the out-patient department with a history of vomiting, thirst, lassitude, and loss of weight; he was readmitted. Much sugar and acetone were present in the urine, the daily amount of which averaged 20 oz. Weight 26 lb. 10 oz., evening temperature 101° to 103° F. He was placed on a diet containing a very small amount of carbohydrates, and alkalies were administered. Investigation of the blood-sugar showed no abnormal increase.

Ten days after admission weakness and spasticity of the left arm developed, followed rapidly by weakness of the left facial muscles and loss of power with wasting of the left leg. The elbow and knee were flexed and the limbs were not used. Later paralysis of the left external rectus developed. The deep reflexes on the left side were absent and the plantar response extensor. Wasting of the muscles occurred. The weight fell to 22 lb.

Improvement was noticed six weeks after admission, and continued steadily, the diet was increased and weight was gained. A further test of tolerance to sugar was performed, and no sugar appeared in the urine. The facial palsy and squint disappeared, and after massage had been given to the limbs voluntary movement was regained. No glycosuria has occurred since recovery, and except for a mild degree of talipes equino-varus with ¼ in. of shortening of the left leg, associated with some weakness, the child is quite well.

I have classified this case as one of polioencephalitis, although there was absence of spasticity in the lower limbs and a residual deformity with some muscular wasting and weakness. There was no evidence either of pancreatic insufficiency or hyperglycaemia.

Medical Societies.

THE MEDICO-LEGAL SOCIETY.

THE MENTAL TREATMENT BILL.

A MEETING of this Society was held on May 15th, Dr. M. A. COLLINS presiding.

Mr. A. H. TREVOR, Commissioner of the Board of Control, read a paper on the Mental Treatments Bill. He said there was practical unanimity in favour of the relaxation of the stringency of the Lunacy Laws, to enable early cases, whether certifiable or not, to be accepted for treatment without certification, and to extend the system of voluntary boarders to all classes. Mr. Trevor selected various clauses in the Bill for explanatory comment, showing first the importance of the extension of the powers of visiting committees. A reduction of the full strength of paid Commissioners from 12 to eight and the delegation of certain duties to inspectors was an economic measure which should receive wide support. Further points of importance were that a patient who regained volition, after having had none, could discharge himself at 48 hours' notice, and that the cost of the keep and treatment of incipient cases would be debited to the General Fund, removing all pauper taint. The Bill dealt only with those willing to be treated, or those who were too ill to know what was taking place. Mr. Trevor explained in some detail the reasons influencing the Government towards placing these patients under the Board of Control. Alternatively a duplicate organisation would have to be set up, for cases of incipient insanity required treatment in many ways resembling that suitable for certified patients. In order to look after their interests, a staff would have to be appointed, differing only in personnel from members of the Board of Control. Separation would also imply the creation of new institutions—a financial impossibility. Moreover, the hospital spirit was growing in public asylums, and this spirit would be damaged by the segregation of early presumably curable cases in a separate institution.

Discussion.

The PRESIDENT said that the aim and object of the Bill must be universally approved. Would the machinery set up attain the desired result?

Sir R. ARMSTRONG-JONES gave as an example of the kind of case that would be benefited by the new legislation that of puerperal insanity, when each successive pregnancy was tinged for the mother with the feeling that she had once been a certified lunatic, and might be again. He regretted that uncertified cases were not to be allowed in approved homes, as well as in public institutions. He did not consider that 48 hours' notice of desire to leave was a sufficiently long period for suitable arrangements to be made. The Bill included no provision for the private affairs of the patient whilst in an institution, and insufficient provision for after-care.

Colonel J. R. LORD was not clear whether visiting committees were to be empowered to combine to provide additional hospitals, like the Maudesley, sanatoria for the treatment of tuberculosis in the insane, and adequate after-care. In New York State certain patients were allowed to resume home life, provided they were visited once a week by specially appointed visitors. These were known as "parole patients," and were also given vocational training. The patient did not leave the books of the hospital until he was fit to look after himself, and until his home conditions were judged suitable. Perhaps some amendment of the Lunacy Act would be framed to achieve this benefit for patients in this country. Provision of after-care should be considered from the economic aspect, lest material help should be given long after the patient had ceased to be insane. The distinction between the voluntary boarders and the

incipient mental cases with volition dealt with in different sections of the Bill seemed arbitrary. According to this Bill every mental hospital might receive voluntary boarders, but only especially approved institutions might receive early incipient cases. Colonel Lord did not consider that every one of our mental hospitals was a proper institution to undertake the care of voluntary boarders. If a patient went as an early incipient mental case, certain formalities were required, but as a voluntary boarder he could go anywhere. If a patient while a voluntary boarder came into a state where volition was lost, he might apparently remain on indefinitely as a voluntary boarder. Thus, when this Bill came into force, the incipient case would have the protection of formal visits from medical men at the end of six months, while a voluntary boarder would not have that advantage. He trusted that the new regulations re inspectors would strengthen, and not weaken, the Board of Control. Colonel Lord considered that, on the whole, the Bill had been admirably framed, but for persons willing and anxious to be admitted into institutions, why so many formalities in recommendation? These were not asked for in the case of a voluntary boarder. He agreed with Sir Robert Armstrong-Jones as to the need for some provision for the care of the patient's property during his stay in an institution. He would recommend the exclusion of voluntary boarders from Section II. and their inclusion under Section IV., so that voluntary boarders and incipient cases would both only go to places approved by the Board of Control.

Dr. M. I. FENUCANE expressed disappointment with the scope and apparent purpose of the Bill, and disapproval of the new machinery set up.

Earl RUSSELL explained that the Bill involved a definite change in policy, extending the available facilities for the treatment of mental disease in two directions—earlier treatment and after-care. Colonel Lord had said in effect that with the new after-care provision, local authorities might maintain neurostenics for life. So they might, but so they probably did now in certain cases under the Poor-law. It was up to electors to choose representatives who would prevent these abuses. The Bill brought no new apparatus. Earl Russell could conceive of nothing more stupid than separation from the Board of Control. The Bill had been well received in the House of Lords. Doubtless through allowing free egress at 48 hours' notice the Bill might in some cases defeat its own object, but the public had great fear of sequestration in asylums, and the Board of Control was doubtless wise in allowing no power to detain patients against their will. He agreed that 48 hours was a short period, but public opinion rightly demanded stringent safeguards for the liberty of the subject. If in practice the working of the Bill was found to be hampered by any of its provisions, these could doubtless be amended later on.

Sir FREDERICK WILLIS, answering Colonel Lord, said that mental hospitals were only to be used for voluntary boarders with the approval of the Board of Control, and this would be refused if any hospitals were considered unsuitable. As to the overlapping between the sections dealing with voluntary boarders and incipient cases, since 1890 private asylums and registered houses might take in voluntary boarders, but not public asylums. It was a widespread desire that this privilege should be available for the poor also. A voluntary boarder was not necessarily an early case, whereas the incipient case it was hoped to bring in under the new Bill was one of early mental disease; places approved for incipient cases would thus have to be especially well equipped. As to power of combination, visiting committees would be empowered to combine for any purpose. The Bill was deliberately drafted to be as elastic as possible.

Dr. J. N. SERGEANT, as a licensee and medical officer of a private asylum, considered that the great value of the Bill was in its brevity. The fact that the faults found in the Bill were mainly those of omission showed that the Bill must be very good.

The PRESIDENT said that the underlying principle of the Bill was to afford to patients suffering from early mental disorders the advantages of patients at a voluntary hospital. For this reason the formalities of recommendation should be reduced to a minimum. One of the most vulnerable clauses in the Bill was perhaps that referring to the non-volition cases, since the state of non-volition was difficult to define.

Reply.

Mr. TREVOR agreed that 48 hours might be rather a short time. In Scotland three days was allowed. As to the approved houses, it might be advisable later to include these, but since these were the only places where any money was made out of the treatment of the insane, it was probably wise not to include them at this stage. As to voluntary boarders, the idea was only to extend to public mental asylums a system which had existed for years in private ones.

ROYAL ACADEMY OF MEDICINE IN IRELAND: THE ROTUNDA HOSPITAL REPORT.

At a recent meeting of the Section of Obstetrics held in the Royal College of Physicians, Dr. BETHEL SOLOMONS, the President, being in the chair, the report of the Master of the Rotunda Hospital for the year November, 1921, to October, 1922, was read and discussed.

Dr. GIBBON FITZGIBBON dealt in his report with 1715 women confined in the hospital, 2022 in the extern department, and 412 patients treated in the gynæcological wards. In the district there were ten deaths, of which five were due to post-partum hæmorrhage; in none of these cases was the patient attended by the hospital until after the birth of the infant, and four of the women were moribund when first seen. He pointed out that the present regulations for midwives did not require this complication to be reported early enough, and that consequently assistance often arrived too late. Eleven cases of placenta prævia were treated in their own homes without a death, all by version. This brings the number in three years to 32 with one death; in the hospital there have been 34 with one death. There was one death from concealed accidental hæmorrhage; in this case the true condition was not recognised until collapse set in, and death occurred before treatment could be adopted. One death was due to cardiac disease with failing compensation during pregnancy. In the intern maternity ward 12 cases of prolapse of the cord were treated and seven infants were delivered alive; one only was extracted with forceps, being in the second stage of labour. Reposition was usually the method adopted and spontaneous delivery awaited. Craniotomy was done in a neglected face case and in a case of posterior sacculation of the uterus following ventral fixation. Only four cases are noted in the report as accidental hæmorrhage; these were the only ones requiring active treatment, many other cases having been admitted and treated by rest, the bleeding stopping spontaneously. Two cases of full-term ectopic pregnancies were treated by laparotomy, and also two cases of rupture of the uterus through scars during pregnancy. As to contracted pelvis, there were 13 cases of marked contraction; 104 patients delivered themselves spontaneously, nine requiring forceps at the end of the second stage. Of the remaining 3 cases, Cæsarean section was required 11 times, six cases being repeated sections. The lower segment operation was done in all the cases operated on for the first time. Pubiotomy was adopted in eight cases as an alternative to craniotomy where there was chance of saving the infant and resulted in four surviving infants, while two others born alive failed to recover. Twenty-eight cases of induction of labour are described in the report. The conditions for which

the procedure was adopted were: severe toxæmia, eclampsia, contracted pelvis, accidental hæmorrhage, and dead fœtus. Dr. FitzGibbon asserts that induction can be carried out with perfect safety and excellent results and offers the most suitable means of dealing with many of the above complications. The methods he adopts are tents where the pregnancy is before the twenty-fourth week and the introduction of a soft rubber tube for more advanced pregnancy. Spontaneous emptying of the uterus is waited for, but where the fœtus has not to be considered, a leg is sometimes brought down after the cervix is dilated to admit two fingers, if the onset of uterine action is slow. The results as regards the child were satisfactory and the maternal convalescence was quite as good as after normal spontaneous deliveries. There were 64 cases of severe albuminuria and 14 of eclampsia without any death. One patient was admitted twice in the year with eclampsia in different pregnancies. The total morbidity in the puerperium (B.M.A. standard) was 6.0 per cent. It was pointed out that this standard includes all cases with a rise of temperature above 100° F. on any two occasions between the second and eighth days, not as is often assumed, two consecutive occasions; this reading of the standard is erroneous. There were two deaths from acute sepsis and only two other cases showed pyogenic uterine infection, one of these being gonococcal. The intern mortality was eight, including cases of cardiac disease, pneumonia, intestinal obstruction by kink, and one case each of abdominal ectopic pregnancy and ruptured uterus.

Discussion.

In the course of the discussion Dr. L. L. CASSIDY congratulated the Master of the Rotunda and his assistants on a report which, he said, maintained the very high standard which the Rotunda had always shown. He disapproved of the high use of forceps. The question as to when labour should be induced in cases of accidental hæmorrhage was a very important one. In cases of long-continued hæmorrhage, he thought that the blood count should be taken, and if the hæmoglobin dropped to 35 per cent., then he was of opinion that labour should be induced. As to contracted pelvis, if every pregnant woman were examined not later than the thirty-second week, more healthy children would be born.

Dr. R. E. TOTTENHAM was satisfied from the report that there was very strong evidence in favour of inducing labour. There were three reasons indicating such a procedure: (1) the pelvis was too small, (2) it did not give as much as a normal pelvis, (3) the baby's head was too big or too hard. He had looked up old Rotunda reports, and it was interesting to note that out of a total of 115 cases where labour had been induced, there had only been four deaths.

Dr. R. J. ROWLETTE noted that there had been two deaths from acute infection; and in neither of these cases had there been a rise of temperature above normal. They were accustomed to see occasionally, in cases of acute surgical sepsis, death occurring without any rise of temperature, but in his experience of the Rotunda Hospital, he did not remember any deaths without rise of temperature. Dr. FitzGibbon had not mentioned what the infection was, but Dr. Rowlette presumed it was streptococcal.

The PRESIDENT said that habitual death of the fœtus was sometimes extremely difficult to combat, and Dr. Solomons felt that in cases where after induction of labour, a baby was either born dead or died within a week, it might be necessary in a subsequent labour to perform Cæsarean section although these cases must be extremely rare. He did not believe that cephalic version was indicated in breech presentation, as the latter was an effort of nature to bring about the easiest method of delivery. The question as to the exact definition of antepartum hæmorrhage for statistical purposes had still to be decided. The original views of the Master of the hospital with regard to pubiotomy were valuable, and he was in accord with them. It was questionable as to whether decapitation of a perforated head

already born made it easier to deliver the body; it seemed better to have the head still attached to the body for traction.

Dr. FITZGIBBON, in replying, said he thought Dr. Cassidy's suggestion of a blood test an excellent basis upon which to decide the question of termination of labour in persistent bleeding in pregnancy; still, when the patients were under observation the progressive anæmia could be well judged, and by the time the hæmoglobin had fallen to the figure suggested the death of the ovum would be usually established as the indication for induction. Dr. Tottenham's figures from previous reports were valuable, but the four deaths even amongst these cases could not be debited to the induction. The operation was done for many serious complications and often as a last resort. Dr. Rowlette referred to the cases of acute infection without a rise of temperature; the infection was streptococcal and the condition was one of collapse setting in from the time of delivery or even before. Dr. FitzGibbon had met other cases with the same collapse reaction from the profundity of the intoxication and the true condition would not have been established without an immediate post-mortem and cultural examination. Version was not advocated for breech presentation, it was done in a case of contracted pelvis in order to estimate the proportions by Müller's method, and in one other case of twins where the first fœtus was presenting as a free breech. The decapitation after delivery of a perforated head was done as the shoulders had to be reduced, the removal of the head enabling the arms to be brought down easily and the shoulders then reduced.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

A MEETING was held at the West London Hospital on May 4th, Dr. A. G. WELLS, the President, being in the chair.

Mr. MCADAM ECCLES read a paper on the

After-Treatment of Abdominal Operations.

He said that it had been contended that only one who had experienced an abdominal operation on himself could adequately treat a fellow sufferer. He could speak from personal experience of appendicectomy. Post-operative vomiting was partly due to the general anæsthetic, but not entirely, for he had seen it occur after spinal anæsthesia. His treatment for post-operative emesis was: (1) to allow the patient a pint of hot water to drink, with 5ss. sod. bicarb. dissolved in it; (2) a saline enema of half a pint was slowly given to relieve thirst, and this, if retained, was repeated in a few hours; (3) the patient was propped up with pillows, as this position stopped vomiting. Flatulence after laparotomy might be due to, at least, four causes: (1) purge and enema previous to operation; (2) a preliminary dose of morphine and atropine; (3) excessive manipulation of bowel, causing paresis; (4) too rigid confinement of abdominal patients to the dorsal position. Early flatulence was certainly best relieved by a pituitrin enema. Of great service was a hot fomentation placed over the whole abdomen superficial to a layer of cotton-wool. Solid food should be given as soon as possible. For late flatulence there was nothing better than a good dose of castor oil. Pain after abdominal operations was best relieved by a rectal injection of aspirin gr. x. and sodium bromide gr. xx. As for diet, except where the intestine had been actually interfered with, the sooner the patient had semi-solid and solid food the better. When a drainage-tube had been inserted it should be removed as soon as possible. A tube pressing against the intestine might cause a fistula within 48 hours of its insertion. As for retention of urine, after operation a catheter should never be passed if it could be possibly avoided. Under the strain of coughing or vomiting abdominal sutures might give way; the actual line of suture should therefore be inspected daily.

BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY.

A MEETING was held on May 3rd, Mr. A. J. HUTCHISON, the President, being in the chair. Dr. H. T. CUBBON read a paper on

Diathermy in Medical Practice.

Medical diathermy he described as the heating through of diseased tissue to a temperature insufficient to destroy the tissue or impair its vitality. The main physiological effects of diathermy were due to its thermo-penetration. The dilatation of the peripheral vessels, increased perspiration, and excretion of solids in the urine aided in the elimination of toxins. The local effects of heat generated in the tissues were to reduce spasm and increase tension with consequent relief of pain. The relief of pain was the most valuable property of diathermy. Subjects of deficient physiological activity of the processes concerned in the production of heat and maintenance of a normal temperature were among those suitable for diathermy. It was an effective method of supplying a supplementary ration of heat in marasmic diseases of children, malnutrition associated with stricture of the oesophagus or cancer of the stomach, and hypothermia following profuse hæmorrhage. Owing to its penetrating power diathermy was useful in the treatment of neuritis and was often of service in relieving the symptoms due to high blood pressure, though the effect appeared to be only temporary. Diathermy was effective in the treatment of pain and spasm due to hæmorrhoids which were not attributable to affections of the liver, heart, or compression of the rectum, and had been found useful in gonococcal infections of the cervix and in gonococcal arthritis before structural changes have taken place. The pain and muscular spasm in cases of lumbago and torticollis of recent origin were often benefited by diathermy, though chronic cases responded better to the constant current. For cases of painful menstruation treatment should be given daily for three days before the expected period and in some cases during the period also. Cases of amenorrhoea for which no obvious cause could be found could often be remedied by diathermy applications of low intensity. The treatment should be given for six days before the period is calculated to be due. Mr. August, of Paris, had had success in treating cases of abdominal pain in which no other lesion beyond adhesions and inflammation of the omentum were present. In coccydynia, great relief and usually complete cure could be obtained by diathermy. One electrode must be placed in the rectum and the other electrode applied externally over to the coccyx. Diathermy must be used with caution in gout; it would be found a useful adjunct to the treatment of infantile paralysis. The temperature of the paralysed limb could be maintained at a normal level by this method and so aid in the restoration of the nutrition of the limb. Until this normal temperature was attained electrical treatment was of little use. Diathermy had been found useful in treating the pain associated with herpetic neuralgia in old patients. Among maladies unsuitable for diathermy were chilblains and Raynaud's disease, which responded better to the constant current. Cases of trigeminal neuralgia did not respond well to diathermy. The treatment of rheumatoid and osteo-arthritis was disappointing.

After remarks by the PRESIDENT, Dr. W. BROADBENT, Dr. HELEN BOYLE, Dr. NEVILLE COX, Dr. G. L. LYON-SMITH, and Dr. J. H. STORMONT spoke, and Dr. CUBBON replied.

Mr. J. R. GRIFFITH then read a paper on the

Treatment of Acute Suppurative Infections of the Fingers and Hands.

He began by expressing his indebtedness to Dr. A. B. Kanavel, who had contributed greatly to our knowledge as to the treatment of these infections. They were dangerous in that they might spread through the

lymphatics into the general circulation and also because they might cause local destruction of tissue both by pressure and by cutting off the blood-supply. Treatment was, therefore, directed towards evacuating inflammatory products and relieving tension by means of incisions which did as little damage as possible and did not involve uninfected spaces. Mr. Griffith discussed the advantage of treating infections of the finger pulp by means of lateral incisions and described the method of treating infections of the nail bed by exposing and excising the root, a flap having been formed by making two lateral incisions continuous with the lateral margin of the nail. The treatment of infections of the fascial spaces of the palm and thenar eminence by means of an incision through the web of the finger and by one through the dorsal aspect of the first interosseous space respectively was also described. Collections of pus in the forearm spreading from the hand were usually situated between the flexor aspect of the interosseous membrane and the pronator quadratus deeply and the flexor tendons superficially. This space might be drained by means of an incision along the anterior margin of either the radius or ulna. This incision avoided important structures. The treatment of infections of the tendon sheaths was then discussed. In the case of the middle finger the importance of providing adequate drainage by means of a long lateral incision was stressed. In infections of the thumb and little finger tendon sheaths the possibility of extension of the infection from one sheath to the other and from a sheath to the neighbouring tissue spaces in the hand and forearm was discussed, together with methods of dealing with these infections and complications. The after-treatment consisted of prolonged arm baths in 2 per cent. saline; early mobilisation was to be encouraged, it did not spread the infection when incisions were adequate.

The PRESIDENT, Mr. H. J. WALKER, and Mr. M. FITZMAURICE-KELLY spoke, and Mr. GRIFFITH replied.

Reviews and Notices of Books.

TEXT-BOOK OF THE SURGICAL DYSPEPSIAS.

By A. J. WALTON, M.S., M.B., B.Sc. Lond., F.R.C.S. Eng., Surgeon, London Hospital; late Surgeon, Poplar Hospital, and Hunterian Professor, Royal College of Surgeons of England. London: Edward Arnold and Co. 1923. Pp. 728. 42s.

THIS valuable book should be in the hands of all those interested in the surgical diseases of the stomach, liver, gall-bladder, and pancreas. The author has dived deeply into the literature, which he presents in an impartial and balanced fashion, giving also his own views, based upon considerable personal experience. Where his clinical observations do not support experimental work done on healthy animals, he does not hesitate to say so. Thus he denies that in man V-resection of the stomach interferes with the emptying of the viscus. Indeed, he regards this resection, combined with gastro-enterostomy, as the method of choice for dealing with an ulcer of the lesser curvature. For pyloric ulcer a simple gastro-jejunostomy is recommended. The author seldom performs the Polya operation except for malignant disease. When we come to the section on the gall-bladder, conservatism gives place to radical measures: cholecystectomy is advanced almost to the exclusion of cholecystostomy. There is a good account of the anomalies of the bile-ducts and cystic artery which may be met with and give rise to trouble during the operation. The author's method of repair of an injured common duct is clearly described. A good review of that crippling condition visceroptosis is given. It is questionable whether the operation of complete colectomy should be included in a book of this kind, and we are glad to see that emphasis is laid upon the futility of any of the operations now in vogue for visceroptosis. We

may not agree with all the conclusions of the author, but without exception they are entitled to respect, based as they are upon personal observation and careful clinical work. All surgeons might not be disposed to admit that the several surgical diseases are associated with such distinctive and clear-cut clinical histories as are described here.

The illustrations are hardly up to the standard of the text. The artist in his attempt to portray what the author wishes to be emphasised, has produced rather crude contrasts and has failed to represent the texture of living tissues. But those which diagrammatically illustrate anatomy, or operative steps, are very satisfactory. It may be ungenerous to take exception to the title of so good a book, but it seems too comprehensive. The indigestion of carcinoma of the colon or rectum is just as much a surgical dyspepsia as the conditions described in this book. Mr. Walton must be congratulated on producing a notable addition to English surgical literature.

MINOR SURGERY.

Ninth Edition. By HENRY R. WHARTON, M.D., Surgeon to the Presbyterian Hospital, Children's Hospital, St. Christopher's Hospital, the Bryn Mawr Hospital, and Girard College. London: Baillière, Tindall and Cox. 1923. Pp. 647. 18s.

THE more time passes since the termination of the Great War, the more accurately is it realised how much less it has influenced modern surgery than many war-born surgeons would have us believe. There are, however, certain lessons which no lapse of time will ever efface, and of these two stand out predominant, the treatment of wounds and blood transfusion. In this ninth edition of his work on minor surgery, Mr. Wharton has devoted much space to these two subjects. He deals first with the immediate excision of wounds, their primary or delayed primary suture, and then passes to the treatment of infected wounds—e.g., by the Carrel-Dakin and other modern methods—and finally discusses secondary suture. The indications for and the technique of blood transfusion are fully discussed. There is nothing in the least difficult in this technique provided that the surgeon understands the method of testing the blood groups, but the text is hardly explicit enough in explaining how the groups are recognised. Certain small points in the manual require adjustment. It is out of place in a work of this kind to describe the technique of arteriorrhaphy as a method of arresting hæmorrhage. Again, we notice (p. 481) that the author, in drawing attention to the complications of fractures of the lower end of the humerus, mentions the loss of the carrying angle. The figure on the same page shows the position recommended in the treatment and explains at once why the loss of the carrying angle results. It is not enough to secure full flexion of the elbow, but the forearm must be maintained in full supination at the same time. In practice this is impossible to obtain if the hand is placed over the opposite clavicle as in Fig. 308. Fig. 169 shows a fracture of the shafts of the tibia and fibula, labelled as a separation of the upper epiphysis of the humerus.

The book is well written, freely illustrated, and should prove of great value to those engaged in dealing with minor surgical problems.

X RAYS.

Fourth edition. By G. W. C. KAYE, O.B.E., M.A., D.Sc., Superintendent of the Physics Department, National Physical Laboratory. London: Longmans, Green and Co. 1923. Pp. 320. 16s.

FROM the point of view of the medical radiologist Kaye's X Rays has been for some years one of the best English text-books on the physical side of the subject. It states as clearly as possible with a minimum of mathematics the essence of what has now become a large and complicated science. The present edition is 50 pages longer than the 1914 edition; but even this is a moderate increase considering the amount of

productive research work which has been done during the last few years. It is interesting to note that the Coolidge tube during those nine years has changed its position from that of a novelty described in an appendix to that of a routine piece of apparatus entitled to an early place in the straightforward descriptions of X ray tubes.

Much of the present edition has been re-written. The largest alteration is the increased space given to crystal structure, X ray spectrometry, and the X raying of materials in industry. Spectrometry from the medical point of view is of great interest, because in the course of time it may be of supreme importance in regulating the action of X ray tubes for purposes of radiography and treatment. The subject of scattered and characteristic radiation is also becoming of increasing importance to radiologists, so that the fuller, surer, and more systematic treatment of the science of these phenomena in this edition will be appreciated by those concerned in medical work. As the question of the protection of X ray and radium workers is now realised to be a vital matter, more space has been given to the consideration of the best means of shielding the operator; the memoranda issued by the X Ray and Radium Protection Committee are given in full in an appendix.

The book as a whole has kept well abreast of the most recent views on X rays and can be recommended for study to all interested in radiology.

BOTULISM AND FOOD PRESERVATION.

The Loch Maree Tragedy. By GERALD LEIGHTON, M.D., F.R.S.E., Medical Officer (Foods) Scottish Board of Health. London: W. Collins Sons and Co. 1923. Pp. 237. 10s.

Dr. Leighton was commissioned by the Scottish Board of Health to draw up an official report of the food poisoning which caused the death of eight persons at Loch Maree in August last. This report appeared as a white paper. The present book is based upon this report, upon discussions with professional colleagues, and a careful collation of the literature. It purports to be an accurate summary of our present knowledge of botulism and the bearing of that knowledge upon the whole subject of preserved foods. The subject of botulism is considered under the headings of history, cause, symptoms, treatment, and prevention, with a chapter on botulism in animals. The concluding part of the book tells the story of the Loch Maree tragedy.

A surprising amount of exact information is now available, as the author shows, in regard to a subject which until last year interested a mere handful of food experts and bacteriologists. The records show a singularly different ætiology in the two countries to which they are practically limited. Botulism has been known in Germany for the past 130 years, about 1200 cases having been recorded with a mortality of 30 per cent. Its former undue frequency in Würtemberg seems to have been due to sausage being prepared from liver and blood for consumption at a later date, the disease being rare in North Germany, where such organs are only eaten fresh. In America 396 cases are on record up to date, of whom 249, or nearly two-thirds, died, the disease having been traced in almost every instance to home-canned fruit and vegetables. It seems that the spores are very widely distributed, for out of 624 specimens of soil, vegetables, fruits, feeds, manures, and sewage investigated from various parts of California, 30 per cent. of the samples yielded toxic cultures. The bacillus is a strict anaerobe, and the potency of its toxin is terrible, for a dose of 1/40,000th of a cubic centimetre is fatal to a mouse. It is only the toxin which is poisonous to man; the bacillus and its spores do not represent a source of danger even if swallowed, although in experimental animals, injected with calcium chloride, botulism may result. In America it has been officially stated that the toxin itself is destroyed by heating to a temperature of 80° C. or a little less. The spores themselves are as difficult to kill as any known living bodies;

they have resisted boiling for 330 minutes or being raised to a temperature of 120° C. for four minutes, and the spores isolated from different kinds of canned products have exhibited a variation in heat resistance from 10 to 230 minutes.

In America certain rules for the home-canning industry have now been laid down which may be briefly summarised thus: (1) To use only clean, sound, and perfect fruits and vegetables; (2) to inspect the container carefully at the time it is opened; (3) to bring all canned vegetables to the boil after opening; (4) to dispose safely of cans of tins suspected of being bad. And in the case of spinach and ripe olives stringent restrictions have now been imposed upon the preservers. The acidity of the preserve has been shown to be of great moment. Most fruits, as well as tomatoes and rhubarb, are so acid as not to be subject to botulinus spoilage if properly packed; in fact, only products which have a higher acid factor than pH 4.5 need to be carefully sterilised. Dr. Leighton holds that the tin is superior to the glass as a container of preserved foods since the glass container in common use does not lend itself to efficient sterilisation. He puts down the unpopularity of the tin in large part to the difficulty in opening, and he foreshadows a fortune awaiting the individual who invents a tin opener which will do its work with ease and comfort and without risk to the operator.

The book is one which may be read with profit by all who are interested in food preservation. The story is well told and the interest is sustained throughout.

PSYCHOLOGY AND PSYCHOTHERAPY.

Psychological Types: or the Psychology of Individuation. By C. G. JUNG, Dr. Med. et Jur. of the University of Zurich. Translated by H. GODWIN BAYNES, M.B., B.C. Cantab. London: Kegan Paul. 1923. Pp. xxii. + 654. 25s.

Jung's work on psychological types and their division into the introvert and the extravert was an extension of observations that had long been common property of philosophers. He shows this in his study of the type problem, where he draws material from classical and mediæval thought, from the theological disputes of the ancient church, and from poet philosophers, before reaching modern thought as expressed by William James and Fernelius Jordan—whose appearance in this company reminds us that one of the most important recent additions to the theory of the herd instinct comes from an English surgeon. Jung now enlarges his classification, and by subdividing in accordance with the basic functions of thinking, feeling, sensation, and intuition, he arrives at no less than eight types; and as he concludes that each type is impelled to seek its own theory of psychic processes, and that each theory must be granted equal validity, he confessedly leaves his readers bewildered. In fact, Jung would seemingly agree to a rough classification of types into those who understand him and those who do not; and those who do not will certainly dismiss a good deal of this book as metaphysical. Still, close reading satisfies one that mankind can be generally classified into his groups, and, since psychologists have to some extent adopted his terminology of introversion and extraversion, his further divisions may find at least a descriptive use. The translator has well performed what must have been a difficult task.

The Psychology of Self-Consciousness. By JULIA TURNER, B.A. Lond., President of the Psychological Aid Society. London: Kegan Paul. 1923. Pp. 243. 6s. 6d.

THIS is a combination of the writer's personal beliefs with what, in contra-distinction to psychoanalysis, is known as analytical psychology. She divides personality into a perceptual and a conceptual self, finding in the latter a source of philosophical speculation which passes into mysticism. "The purpose of the conceptual life is the mystery of mysteries" (p. 168) prepares us for something specu-

lative, but not for the news, concerning the conceptual subject, that "his life being one of thought and feeling only, it is independent of immediate sensory stimulation," which calls up to the medical psychologist an image of dementia præcox and is, indeed, a conception closely akin to that of schizophrenia. The writer's incursions into medicine may find justification in our tendency, as she puts it, to regard the human economy as merely a piece of physiological mechanism, but she places herself in the category of impossible enthusiasts when (in page 9 et seq.) she seems to believe that the root of all disease is in the mind. The book is sincere, but leads into realms where emotional aspirations replace the prosaic study of causes and effect.

Psycho-analysis and Suggestion Therapy. Their Technique, Application, Results, Limits, Dangers, and Excesses. By DR. WILHELM STEKEL. Authorised translation by JAMES S. VAN TESLAR. London: Kegan Paul. 1923. Pp. 155. 6s. 6d.

THE publisher's notice of this book says that it is designed for the busy practitioner and the sufferer from "nerves," but whoever makes it his first acquaintance with the subject will surely reject most of the contents. Dr. Stekel actually has great clinical experience behind his dogmatism, but he hurls the dogma at the unprepared reader in a way that causes aversion. There is good material in the book, and its crudities are partly atoned for by the author's frank discussion of his own difficulties and failures, but its usefulness to the practitioner is doubtful. The suggestion that a book of this nature is suitable for the sufferer from "nerves" is to be strongly condemned.

BRAIN ABSCESS.

Its Surgical Pathology and Operative Technic. By WELLS P. EAGLETON, M.D., President of the American Otological Society. London and New York: Macmillan and Co. 1922. Pp. 297. 31s. 6d.

A SURGICAL text-book to-day may be written for one of two purposes. Its sole purpose may be to serve as a manual of teaching, in which case it will give a complete account of accepted principles, or it may aim at presenting new work and so advancing a special branch of surgery. The work under review does not naturally fall into either category. It certainly does not follow the accepted teaching of the subject, nor does it enter sufficiently into details to be regarded as a monograph of new work. The arrangement of material is open to criticism. In the first two chapters small paragraphs are given to the technique of operation; these are not only useless, but leave the inference that they are the only description given of the author's operation, whereas a fuller account is given on page 40. The pathological considerations in the early part of Chapter III. are sketchy and can be dismissed as padding. The varieties of abscess are classified anew, being described as secondary or adjacent and intercurrent or tertiary. This classification is cumbersome and does not give any practical help. Indeed, it is difficult in reading the book to obtain a clear idea of the subject, for in passing from chapter to chapter there appears to be little or no continuity. There are embodied, however, several important conclusions based upon the author's work. This experience includes a list of 31 personal cases and an analysis of 270 post-mortem records of cerebral and cerebellar abscess.

The most valuable part of the work is that which deals with the differential diagnosis between abscesses with and without a capsule, and the description of the appropriate treatment of each. It makes widely known the fact that every effort must be made to preserve the capsule, and to avoid by trauma infection of the brain tissue. The routine treatment advocated is the formation of a large osteo-plastic flap in the temporo-sphenoidal region, but it is difficult to see why a superior pedicle is advocated, for the blood-supply is much less satisfactory thus than with the

usual inferior pedicle. The author confesses in a foot-note that the majority of such flaps have been infected when an abscess has been located. The analysis of post-mortem cases is given in the form of two appendixes, but these mainly consist of the author's name and a heading of condition found, although occasionally there is a note of a few symptoms. Although the original descriptions may have been of great use to the author, his abstracts are of small value for reference, as they teach no lesson either good or bad.

The symptomatology is certainly the strongest part of the book, and from this aspect the work will be found useful to those engaged in this branch of surgery.

A MONOGRAPH ON GONORRHOEA.

By A. REITH FRASER, M.D. Aberd., Lecturer in Venereal Diseases, Cape Town. London: Henry Kimpton. 1923. Pp. 508. 18s.

THE author says in his preface: "This monograph is frankly a plea for the conservative treatment of gonococcal urethritis and for the management of gonorrhoea as a general systemic disease instead of a local specialised catarrh." Further on he expresses the hope that the book will stimulate new lines of thought, dispel old and mistaken dogmas, or replace certain accepted conceptions in their true perspective. After this it is a little disappointing to find a text-book on gonorrhoea without any very new ideas or methods and not including all that is known to date on the subject.

The treatment is laid down in discursive fashion. It is sound enough, but the manner is not concise and not always clear—for instance, Dr. Fraser advises giving a patient in the acute stage in place of novels some heavy work requiring thought and concentration relating to his trade or profession, and two pages later advises against "all active exercise." In the matter of posterior gonorrhoea space is wasted in tilting at the mythical person with a mania for urethroscopy. The section dealing with gonorrhoea in the female is too sketchy to be of value to the serious reader and might have been omitted. The main teaching of the author seems to be caution in treatment—a sound dogma, but apt to be overdone. Dr. Fraser is an enthusiast for vaccine therapy.

There is much that is of value in the book, but it contains too many general statements and too little that bears the stamp of personal experience.

GLANDS IN HEALTH AND DISEASE.

By BENJAMIN HARROW, Ph.D., Associate in Physiological Chemistry, College of Physicians and Surgeons, Columbia University. London: George Routledge and Sons, Ltd. 1922. Pp. 218. 8s. 6d.

"MONKEY glands: clever men and stupid ones; glands as the cause of crime; the origin of races; the mentally unbalanced; many acute diseases; 'the bearded lady, the giant, the fat boy, and the midget'—all these and more have been dealt with under the subject of the glands of internal secretion." The present volume, though only of an elementary standard, contains a great deal of sound information presented in an interesting manner; it is suitable for either the general reader or for the practitioner who wishes to obtain trustworthy views on the subject, but has no time for heavier treatises. The book contains no reference to the recent work on the internal secretion of the pancreas, no doubt because this appeared while it was in the press—an illustration of the kaleidoscopic nature of the subject. In the chapter on the reproductive organs we have an interesting presentation of the rejuvenation methods—the putting of "new wine into old bottles"—which has of late attracted some attention. These methods are vasectomy, exposure to X rays, and transplantation of testis. Of these methods, that of vasectomy is most favourably viewed, because it results in actual hypertrophy of the interstitial tissue of the subject's

own testis. The effect of X rays is less certain, while with grafts the improvement ceases as soon as the graft has all been absorbed.

We congratulate the author on producing a sensible book for popular use.

THERAPEUTISCHES VADEMEKUM FÜR DIE KINDER-PRAXIS.

Fourth and fifth edition. By H. KLEINSCHMIDT. Berlin: S. Karger. 1923. Pp. 227. M.3.

Prof. Kleinschmidt, who directs the Children's Clinic at Hamburg University, first published this compilation in 1918. A short preliminary section on the general principles of treatment in children's diseases is followed by 24 pages on the subject of infant feeding in health and illness, breast-feeding, as well as "unnatural" or artificial feeding, receiving brief but adequate attention. Useful chapters on the diseases of the new-born and on disorders of nutrition in the infant are introduced, but the main portion of the book consists of a synopsis of treatment, the diseases being grouped alphabetically under the various organs or systems mainly affected. A subject-index obviates any difficulty in cross reference. Prophylaxis as well as treatment is considered, and occasionally attention is drawn to symptomatology where difficulty may arise, as in the differential diagnosis of myelogenous purpura. The therapeutic measures advocated are representative of current medical practice on the Continent. This is especially the case where serum-therapy is concerned—e.g., the injection of serum from a convalescent case is recommended both in the prophylaxis of measles and in the treatment of severe cases of scarlet fever. In the section on diphtheria, however, while recommending that the brothers and sisters of the patient should be protected by the intramuscular injection of 500 units of antitoxin, Prof. Kleinschmidt makes no mention either of the preliminary Schick test, which should always be carried out where possible in children over 3 years of age, or of the toxin-antitoxin method of immunisation, which is so largely used in America, and is believed to confer a very much longer period of immunity than the three weeks' protection afforded by the author's method—omissions which might be remedied in a future edition. The important place of diet in the treatment of many diseases is emphasised, and a number of simple recipes included.

A vast amount of information has been compressed into the 227 pages of this useful volume.

BOOKS FOR NURSES.

A Handbook for Mental Nurses. Seventh edition. Published under the authority of the Medico-Psychological Association. London: Baillière, Tindall and Cox. 1923. Pp. 640. 6s.

A COMMITTEE of the Medico-Psychological Association has been at work for two years in producing this book. Each section of it has been rewritten either by a member of the committee or by an authority appointed by them, and subjected to close scrutiny and revision at the meetings which have taken place since the committee was set up in 1920. The result is a volume of much greater length and scope than its predecessors. It occupies a unique position among text-books of mental nursing, for not only is it adequate to the needs of nurses at any stage of their training, but it carries an authority which no text-book by any single individual could possess. There are no small difficulties in producing such a work. Every mental nurse is intended to possess it, and a mental nurse may be either a highly intelligent and cultured woman with a previous general hospital training, or a man or woman lacking in some of that mental equipment and with no previous experience of any kind of nursing. The same mode of address is not appropriate to each of these individuals. The introductory chapter on the general conduct of a nurse, for example, was evidently written with the latter type in view, whereas some of the later sections presuppose for their proper understanding a much

higher degree of general intelligence and education. This inequality is not only a natural effect of multiple authorship; to some extent it is inevitable in dealing with subjects ranging from matters of the merest common-sense to academic psychology.

Another aspect in which compromise was inevitable is the treatment of general nursing matters. To have made these sections complete would have been to produce two text-books in one, and to go beyond the present scope of a mental nurse's training. On the other hand, to omit brief descriptions of common diseases and their nursing requirements was impossible. An example of what this means is to be found in the paragraph on diphtheria. The only instruction given as to the preparation for tracheotomy and subsequent dressings is to have at hand a plentiful supply of sterilised feathers. The remarks on the nursing of typhoid and rheumatic fever are also too brief to be of service; a nurse responsible for such cases would be compelled to consult other works, or to depend entirely on the instructions of a medical officer. Such patients would, of course, often be placed in the care of nurses with a general training, and the real question underlying the whole matter is whether asylum nursing staffs should not be recruited to a greater extent from those who have undergone such training elsewhere, or, on the other hand, whether facilities should not exist for providing a larger number of mental nurses with training at a general hospital at a later stage in their careers.

A still wider question is exemplified in the sections which treat of psychology, and the anatomy and physiology of the central nervous system. The descriptions given of such structures as the spinal tracts and the basal nuclei would appear formidable at first sight even to the medical student. It is, however, impossible to describe the mechanism of the nervous system in a manner so simple as to be understood immediately by an un instructed reader, however intelligent. Although the scope of the handbook corresponds to that of the syllabus of training for mental nurses laid down by the Association, it is not implied that an exact knowledge of everything contained in the handbook is required. The more difficult and theoretical sections are inserted for the benefit of those who are inclined to the study of this aspect of their subject, and the handbook is therefore to be regarded as a work of reference as well as a text-book.

The chapters dealing with insanity, and with the practical aspect of mental nursing, are beyond criticism and beyond praise. The care with which the preparation of this edition has been undertaken is reflected in its up-to-date and accurate information, in its clear style, and in the attention to practical points.

Text-book for Fever Nurses. By GRACE H. GIFFEN DUNDAS, F.R.C.S.I., D.P.H. Camb. Edinburgh: W. Price. 1923. Pp. 202. 4s. 6d.

Mrs. Dundas's small book on fever nursing is useful as far as it goes, but it does not go far enough; of the 202 pages, 89 only are devoted to infectious fevers. There are so many excellent books on anatomy and physiology that the eight chapters devoted to these subjects might well have been omitted in favour of some account of typhus, cholera, and infective diarrhoea, which would have been invaluable to those hoping at some time to nurse abroad.

C.M.B. Examination: Questions and Model Answers. A Handbook for Nurses entering for the Central Midwives Board Examination, with Abridged Rules and other Useful Information. London: The Scientific Press, Ltd. 1923. Pp. 125. 1s. 6d.

THIS little book not only contains model answers to questions set at the Midwives Board examinations, but also information on how to become a midwife, institutions, &c., at which pupil midwives may be trained, an obstetrical table, and the rules of the

Central Midwives Board abridged. The model answers to the questions are well arranged and thorough, and should prove useful to nurses taking these examinations. The volume as a whole is an excellent little publication.

New Inventions.

A NEW KIDNEY REST.

THE many contrivances which have been made use of in kidney operations for the purpose of maintaining an anæsthetised patient in the lateral position, and at the same time widening the interval between the lower ribs and the crest of the ilium, suffer from the common defect of having to be placed in position after the patient is unconscious. To avoid this defect I have devised a kidney rest which is fixed to the operating table and can be elevated or lowered by means of a key. The apparatus, as is shown in the illus-

tration, consists of a flat base trough adapted to lie transversely across the operating table with a pair of hooked clamps at each end to grip the table edge. One pair of these clamps is extensively adjustable to accommodate the device to various widths of table. A rotatable spindle is mounted in the trough having right and left screw threads at each end respectively and a rounded elevating table is carried by trellis links connected to the base and to brackets running on the opposite threads of the spindle, so that rotation of the spindle contracts or expands the trellis and raises or lowers the elevating table. The whole elevating mechanism lies concealed between the flat base trough and elevating table. A back-rest is fixed to the elevating table by means of a stirrup-shaped clamp and can be easily removed; while an arm support is detachably connected to the base on the opposite side. The apparatus weighs 12 lb. and can be put into a wallet 20 in. x 6 in.

The rest is made by the Genito-Urinary Manufacturing Company, Ltd., 66, Margaret-st., London, W.

CLIFFORD MORSON, O.B.E., F.R.C.S. Eng.

Welbeck-street, W.

AN IMPROVED OPHTHALMOSCOPE.

HAVING used an ordinary electric ophthalmoscope for some time, I found that if the light was sufficiently powerful to see the disc in an ordinary room there was a haze round the slot in the mirror and also from the transverse beam. I tried various forms of mirrors—glass, steel, and silver—but could not obviate this haze and back light from the slot. I then tried building a small hood round the slot but found this interfered somewhat with the vision. As a last resort I decided to try having a glass prism slotted. This I entrusted to Messrs. George Spiller, Ltd., who took a careful interest in the work and produced a small silvered prism, with a slot for vision. With this they have now made for me an ophthalmoscope, from which there is no back light or haze, so that the light can now be much stronger and a good view of the disc obtained in full daylight.

ANTE-PARTUM HÆMORRHAGE.

HÆMORRHAGE from the gravid uterus during the last three months of pregnancy is one of the gravest of all obstetric complications. It is sufficiently frequent for every practitioner of midwifery to see a fair number of cases, and its importance as an integral factor in the mortality of childbearing is shown by the figures to be found in the Registrar-General's Reports for England and Wales. Since the year 1915 deaths from placenta prævia have been separated from the other "puerperal hæmorrhages" as they are entitled in the reports, and it appears that about 200 deaths from placenta prævia alone occur every year. The deaths from accidental hæmorrhage are not given separately, but it will not be far off the mark if we assume that from 300 to 400 women lose their lives in England and Wales every year from ante-partum hæmorrhage. It is impossible to form any accurate estimate of the frequency of its actual occurrence since the requisite data do not exist; only the cases which end fatally are on record. We know, however, what numbers of cases of ante-partum hæmorrhage are admitted to our lying-in hospitals; these are, generally speaking, the most severe cases, and one or two interesting points may be gleaned from a study of the annual reports of these hospitals. Ante-partum hæmorrhages appear to be much more frequent in the practice of hospitals serving industrial districts than in London. Thus in a London lying-in hospital (Queen Charlotte's) over a recent period of five years the numbers were 21 cases of ante-partum hæmorrhage per 1000 cases admitted; in a Midland industrial district (Birmingham) they were 85 per 1000 cases admitted, and in a third hospital serving a northern industrial district (Manchester), 58 per 1000 cases admitted. Perhaps the larger proportion of women engaged in fatiguing occupations in the industrial towns accounts for the higher number of severe cases of ante-partum hæmorrhages occurring in those districts. All the reports agree that placenta prævia is more frequent than accidental hæmorrhage, the proportion varying from 55 per cent. of the total in London to 75 per cent. in Birmingham; the mean relative proportion is about five cases of placenta prævia to four of accidental hæmorrhage. The relatively high proportion of cases of accidental hæmorrhage in London (45 per cent., as compared with 25 per cent. in Birmingham) is surprising and very difficult to account for. The relative severity of the two kinds of ante-partum hæmorrhage is also curiously unequal in the different districts, as will be seen from the following rates of maternal mortality:—

Maternal mortality.

	Placenta prævia (per cent.).	Accidental hæmorrhage (per cent.).
London	7.3	1.2
Birmingham	4.6	3.1
Manchester	7.2	9.6

The high mortality of accidental hæmorrhage in Manchester and its very low mortality in London are interesting points which would perhaps repay further inquiry. The average mortality rate of

placenta prævia over these total figures is about 6.7 per cent. and that of accidental hæmorrhage about 4.6 per cent., the former being thus nearly 50 per cent. more dangerous than the latter. This relation probably expresses fairly accurately the comparative severity of these two forms of hæmorrhages.

The classification of cases of ante-partum hæmorrhage, in accordance with the situation of the placenta, into *placenta prævia* (or unavoidable hæmorrhage) and *accidental hæmorrhage* is universally adopted in all countries and is of great practical value. The importance of endeavouring to arrive at a differential diagnosis, the value of which is often underrated by practitioners, lies in the fact that the treatment of the two conditions is by no means identical. The difference in treatment depends upon three important points of difference in prognosis. First, in a case of placenta prævia labour rarely ensues upon the first hæmorrhage; repetition of the hæmorrhage is certain to occur, and a sudden profuse bleeding may at any moment bring the patient to a point of extreme danger; in a case of accidental hæmorrhage, on the other hand, labour more frequently accompanies or rapidly succeeds the first hæmorrhage; if labour does not set in and pregnancy continues, it is quite possible that no further bleeding will occur, and normal labour may bring the case to a favourable termination, either prematurely or even at term. Secondly, the delivery of the patient in cases of placenta prævia is a much more difficult obstetric problem than in accidental hæmorrhage. Thirdly, the maternal mortality of the former is, as we have seen, 50 per cent. greater than that of the latter.

In the twenty-first article of our series on modern technique in treatment Dr. T. W. EDEN sets forth the considerations which should influence decision on the line of treatment to be adopted in ante-partum hæmorrhage from either cause. It is clear that the presence or absence of albuminuria is a vital point, and one of the first things to be done by a practitioner confronted with a case is to secure a catheter specimen for examination. Accidental hæmorrhage is accompanied in about 80 per cent. of cases by albuminuria, frequently also by other toxæmic symptoms, such as oedema, headache, and vomiting. In other words, a toxæmic condition is present, which is probably the essential cause of the hæmorrhage from the placental vessels, and eliminative treatment is therefore indicated. If all cases of accidental hæmorrhage could be kept under continuous observation after the first attack of bleeding, and prophylactic treatment diligently carried out, the mortality would probably be greatly reduced and few really serious cases would be seen. In this respect accidental hæmorrhage differs from placenta prævia, where prophylaxis is impracticable. The bleeding results from the vicious situation of the placenta in the lower uterine segment, and since its recurrence is unavoidable there is no object in temporising. In a case where labour has not begun the problem resolves itself into the choice between induction of labour and Caesarean section, and Dr. EDEN indicates the main facts which ought to influence the decision. In discussing the methods to be adopted when hæmorrhage occurs during labour he excludes the use of de Ribes's bag except in hospital practice and under limited indications. This is indeed a method of dilating the cervix rather than a method of delivery. It is alleged to give a better chance of survival to the infant, but this has not been proved, and since it has certain disadvantages in comparison with podalic version the latter is likely to be favoured by most practitioners. The principles

which should be applied in the treatment of cases of different varieties of ante-partum hæmorrhage are most clearly set out by Dr. EDEN, and his article should be of great assistance to those engaged in the practice of midwifery.

THE SUPPLY OF INSULIN.

ON April 21st, 1923, the Medical Research Council published a statement setting forth the steps that had been taken to make insulin available for use in this country. At that time the supplies of insulin were inadequate to meet the demand that might be expected, and it became necessary to secure that the limited quantities available should be distributed to the best advantage. The question was submitted by the Council to the Minister of Health, who appointed a Committee composed of Sir GEORGE NEWMAN (chairman), Dr. R. A. BOLAM, Sir WALTER FLETCHER, Sir HUMPHRY ROLLESTON, Dr. ALFRED SALTER, M.P., Dr. McCLEARY (secretary) to advise him on distribution. On the advice of the Committee the manufacturers were directed during the period of restricted production to supply insulin for use in this country only, and to those hospitals and to those registered medical practitioners who undertook to observe certain defined restrictions upon the use of insulin. The following additional statement can now be made. During the past four weeks the productive capacity of the British firms has considerably increased, and it is no longer necessary to maintain the restrictions upon the supply of insulin, which, therefore, may now be obtained from the manufacturing firms through the ordinary commercial channels. But the Council consider it advisable again to remind the members of the medical profession, who desire to use insulin, of the great importance of making accurate blood-sugar determinations, of correlating the diet, the blood-sugar changes and the insulin dosage in each case, and of avoiding the danger of giving insulin in cases of renal glycosuria or other non-diabetic conditions.

We publish in THE LANCET this week an address delivered by Prof. HUGH MACLEAN before the Congress of Public Health at Scarborough on the present position of medicine in the diagnosis and treatment of glycosuria. He shows how newer methods in investigating glycosuria have made possible a classification of the cases presenting glycosuria as a prominent symptom, and makes it clear that a study of blood-sugar reactions is necessary for scientific therapeutics. The value of insulin, and the general outlook for its employment, are outlined at the termination of an interesting exposition of the whole subject, and Prof. MACLEAN's conclusions exactly support the words of advice closing the statement of the Medical Research Council. He notes that blood-sugar determinations must be taken with great care by those who employ insulin, and that diet must always be correlated to insulin dosage, for only in this way can there be any reasonable certainty that it is right to administer the product, or that the procedure will be perfectly safe for the patient. For insulin is a powerful remedy, and in the hands of inexperienced users serious difficulties may arise during its exhibition.

We are glad to announce that insulin can henceforth be obtained through the usual commercial sources, and may take this opportunity of congratulating alike the Medical Research Council and the manufacturing firms concerned on the results obtained. When the Council accepted from the University of Toronto the

exercise of protecting powers and controlling discretion in the matter of the production and distribution of insulin there was some criticism of the position produced, as being foreign to medical tradition. But we feel assured of two things. The intervention of the Council has enabled a supply of the standardised production to be far more promptly available than would otherwise have been the case, while the risk of valueless imitations being put upon the market has been avoided.

VISCEROPTOSIS.

THE excellent survey of visceroptosis given in Mr. A. J. WALTON's "Text-book of the Surgical Dyspepsias," which we review in another column, recalls attention to a morbid entity of no little complexity. Since GLÉNARD first described the condition of dropping of the abdominal viscera, to which his name is often applied, a great deal has been written on the subject, but there is as yet no consensus of opinion as to its nature, causation, symptomatology, or treatment. Even its nomenclature is protean and confusing. Glénard's disease, enteroptosis, and splachnoptosis have been used to express the general condition of sagging of the abdominal viscera, while the terms gastropptosis, hepatoptosis, nephropptosis, coloptosis, and uterine prolapse show how the displacement of individual organs has attracted attention. The comparatively recent name of visceroptosis, though perhaps not elegant, is expressive and comprehensive. At any rate it may serve to emphasise the fact, which should be obvious, that the whole includes the parts, and that the condition is usually general not local. The history of this condition makes somewhat melancholy reading. There has in many instances been a lack of true perspective in its consideration. The various operations proposed to deal with individual displaced organs have had their vogue and have, for the most part, failed to establish their value, except in a few well-recognised mechanical results of the sagging. That the condition of visceroptosis may be associated with most profound discomforts and disabilities is familiar to most practitioners. On the other hand, it is becoming recognised, since the wide use of X ray examinations of the abdominal viscera, that very marked dropping of the intestines, and especially of the colon, may be consistent with sound health and active bodily functions.

Visceroptosis has recently been the subject of discussion at the Chelsea Clinical Society and the report of the debate, which was published in THE LANCET of April 7th (p. 698), well illustrates the differences of opinion which still exist in regard to this condition. The opener, Sir CHARLTON BRISCOE, maintained that the visceroptotic habit or tendency was produced early in life. He suggested that conditions which tended to induce predominant abdominal respiration helped to develop visceroptosis. He urged due attention to such matters as the position of children at desks, nasal obstruction from adenoids, and frequent colds, fatigue, and over-exercise. He also advised proper exercises and measures to develop the upper chest. Mr. IVOR BACK questioned whether visceroptosis existed as a pathological or clinical entity, and cogently pointed out how our views of the normal position of the viscera, as studied by the X rays, had rendered it necessary to modify the older views obtained from

dissection and from formalin-hardened bodies. He referred to the practical discrediting of nephropexy except for comparatively rare cases in which the dropping of the kidney was mechanically responsible for the symptoms produced, as in Dietl's crises, and he suggested that the operation of colopexy would prove to have a similarly limited field of usefulness. Dr. ROBERT HUTCHISON, in a noteworthy contribution to the discussion, claimed that visceroptosis was a definite clinical entity, but pointed out some of the difficulties in connexion with it, notably its almost constant association with neurasthenic manifestations and the fact that it not infrequently produced symptoms simulating acute organic abdominal disease such as gall-stones or gastric ulcer, while on the other hand it might be present without symptoms. Dr. HUTCHISON criticised the views expressed by Sir CHARLTON BRISCOE as to causation, suggesting that in women, in whom the condition was most often found, diaphragmatic breathing was less common than the thoracic type. He thought that the size of the pelvis in women and derangements of its floor, particularly as a result of pregnancy, were of more importance, together with a loss of the supporting fat within the abdomen. He suggested that the symptoms developed when atony of the visceral muscle resulted, or when weakness of the abdominal muscles led to diminished intra-abdominal tension. He recommended the adoption of measures to strengthen the abdominal walls and to repack the abdomen with fat. He thought that the relief sometimes afforded by belts was not due to the holding up of the viscera but to the increasing intra-abdominal tension. Several of the speakers maintained that visceroptosis was of congenital origin. Dr. F. HERNAMAN-JOHNSON recognised two types: one commonly following pregnancy and due to laxness of the abdominal walls, this form being preventable by suitable precautions and treatment; the other type, which he regarded as congenital, occurred in tall, thin women. Dr. J. CAMPBELL McCURE, the President, referred to the two opposing innervations of the alimentary tube—viz., the vagus and the sympathetic—and believed that a lack of balance between these innervations might result in gastro-intestinal stasis, and was anyhow an important factor in the production of symptoms.

The chief outcome of the discussion is to emphasise the gaps in our knowledge of visceroptosis and the far from satisfactory means of treatment at present available. That there is a need for individual and collective research must be obvious. The one point of general agreement seems to have been that the rôle of surgery in the treatment of this condition is a strictly limited one. The plea put forward by several of the speakers for preventive measures in the form of proper rest and support after pregnancy and for means to improve the abdominal musculature and visceral tone of those prone to the disease, deserves careful consideration. The concomitant nerve manifestations and the neurasthenic state, so often associated, received but little consideration. They constitute perhaps the most troublesome and distressing features of the condition. They are difficult to explain and still more difficult to treat. It is probable that the complex symptomatology is due to various combinations of mechanical, toxic, nervous, and endocrine factors. The recognition of the rôle of each of these and the determination of their relationship to one another should do much to clear up the causation and pathology of the condition. This discussion should stimulate fresh endeavours to put treatment on a more satisfactory basis.

Annotations.

"Ne quid nimis."

THE LISTER INSTITUTE.

THE annual report of the governing body of the Lister Institute of Preventive Medicine was presented at the general meeting of members on May 16th, and gives an interesting summary of the activities of that institution; some of the results of the activities of that done by members of the staff and others working there have also recently been distributed in the annual volume of collected papers. Among a great variety of important topics, the chief place is taken by the investigation of accessory food factors. On the experimental side the work of Prof. Korenchevsky, Dr. Goldblatt, Miss Hume, and their collaborators on the relation of diet to growth and rickets in rats will be familiar to our readers, and in the more difficult clinical field Dr. Harriette Chick, Dr. Dalyell, Dr. Mackay and their co-workers achieved a considerable advance in our precise knowledge of human rickets at Prof. v. Pirquet's Kinderklinik in Vienna. Prof. Harden, Dr. Zilva, and Dr. Schütze have also been engaged on various aspects of vitamin problems. The department of bacteriology under Prof. Ledingham has investigated diphtheroids, tularæmia, typhus, blood-platelets, streptococci, the bacteriophage, protein therapy, the carriage of cholera vibrios by ship cockroaches, the relationships of the bacilli of bovine abortion, and Malta fever among other subjects. At the serum department at Elstree Dr. MacConkey has been chiefly engaged in the stability of toxin and antitoxin standards and the concentration of antitoxin sera. As many working bacteriologists could testify, the National Collection of Type Cultures, established at the Institute with the help of the Medical Research Council, has been a great success. Among much happy progress, there are unfortunately several deplorable events. Chief among these is the loss of that wonderful disciple of true learning, Mr. A. W. Bacot, who died of typhus contracted in Egypt during his work there on the disease; Dr. Arkwright also took it, but fortunately recovered. In maintaining the virus of the Californian disease, tularæmia, in the Type Collection, Dr. Brooks, Dr. Schütze, and Miss Rhodes all caught the infection, as have most people who have worked with it. We notice, too, with regret that the University of London appears to have now entirely withdrawn its support of the protozoological laboratory, and the absence through illness of Dr. Robertson is also mentioned. In face of a good many difficulties, however, the work of the Institute has continued to progress on the high level which it has set and Prof. Martin is to be congratulated on another successful year. The financial position is satisfactory in so far as there is a balance on the right side; but about two-thirds of the money which is spent in maintaining research has to be earned in a rather precarious market by the manufacture of sera, &c., and this uncertainty of income naturally hampers the governing body in embarking on any fresh schemes which involve any lasting financial responsibility. Twenty-nine years of service so good as that which the Institute has given to the cause of preventive medicine deserve a more comfortable stability.

SYPHILIS OF THE SECOND AND THIRD GENERATION.

BESIDES the ordinary congenital syphilis of the first generation which parents transmit to their children there are other much rarer forms in which the disease is transmitted from the grandfather to the grandchildren, or from the great-grandfather to the great-grandchildren. Observations, which are not numerous but of great interest as coming from authoritative sources, appear to leave no doubt as to the existence of

this form of hereditary lues, and while Brunisgard expresses the opinion that this form can only be transmitted by a mother who is definitely syphilitic, yet Gaucher, Clover, and others have shown that the heredity can also be transmitted by a father or by both parents. Prof. Carlo Martelli, of the University of Naples,¹ has collected nine cases which disclose further interesting facts regarding this condition and from which it appears that though it is easy to understand a toxic, dystrophic, and non-parasitic transmission from the grandfather to the grandchild through the father, these cases do not imply a virulent syphilis in which transmission is connected not with toxins but with active treponemes. In Prof. Martelli's cases relating to numerous grandchildren of various grandparents and great-grandparents, nearly all of maternal origin, there is almost always found a vigorous defensive humoral reaction with presence of antibodies in the serum and a strongly positive Wassermann reaction. In most of the cases the subjects of syphilis of the second generation are weak, prone to all those ailments which easily conduce to a fatal result—and sometimes without appreciable cause, disposed to general dystrophies, such as infantilism, dwarfism, and dental malformation; but on the other hand cases are not wanting, like those described by Prof. Martelli, in which the grandchildren are found possessed of all the best somatic and psychic developmental endowments, so that only an accurate investigation is successful in revealing the slight anatomical and functional stigmata of the disease transmitted by the grandparents. Rarer than hereditary syphilis of the second generation is that of the third generation, in which the great-grandfather transmits the disease even to the great-grandchildren. Such an event requires a lapse of so much time that the opportunity of following it to its conclusion is rarely afforded, yet a case of this character exists in literature and was communicated by Gaucher to the Academy of Medicine of Paris in 1916.

In this case the great-grandfather died of syphilitic paraplegia, according to reliable information furnished by the son; the grandfather, personally known, had numerous stigmata of hereditary syphilis and died of cerebral hemorrhage; the father was healthy and had never contracted syphilis yet gave a positive Wassermann reaction. He married a woman with negative reaction and had three children affected with hereditary syphilis, one, a girl aged 9 years, with scoliosis, adenoids, and notched incisors, another, a girl of 6 years, almost an imbecile, with flat nose, uneven teeth, and convergent strabismus.

One of Prof. Martelli's cases carries this form of familial syphilis as far as the fourth generation.

The great-great-grandfather suffered from dementia of specific origin, his daughter (the great-grandmother) died at the age of 75 from biliary calculus, having married a widower, who died of diabetes, but was free from syphilis and had had three healthy children by a former wife. This marriage resulted in 16 pregnancies, four being abortions and four dying at an early age; two others became grandmothers one of whom had a strongly positive W.R. and married a healthy individual, giving birth to seven children, three of whom died at an early age, one had spinal neurasthenia, another died of oedema of the glottis, and a third had rickets; the remaining child, who was clinically healthy, yet had a weakly positive W.R., married a healthy man and had three children, one of whom suffered from dwarfism, another from hernia, the third being as yet unborn. Of the second generation, three became mothers; one having a weak positive W.R. gave birth to two normal children and to one mentally deficient and one with a weak positive W.R. The second mother having a strongly positive W.R. had two children, one of whom died at the age of 2 years from convulsions, while the other was apparently normal. The third mother had a strongly positive W.R. and gave birth to four children, one with adenoids and notched incisors, two with adenoids, while the fourth was a degenerate.

Like alcoholism in the Rougon-Macquart family, so syphilis sends down its stigmata to the third and perhaps fourth generation. It may not conform to the classical description, but descends among the offspring and infiltrates everywhere to a more or less extent without following fixed laws and, more often than not, without giving rise to any specific mani-

festations, such as syphiloderma and polyadenia. In Prof. Martelli's opinion syphilis of the second generation, overlooked in the majority of cases, is much more frequent than is generally believed, and if medical men, who have the opportunity of practising for 50 years in small localities among a known population, know how to recognise it, probably even the heredity of the third generation would prove to be less rare, as his own cases show.

THE ROYAL SOCIETY CONVERSAZIONE.

AT the conversazione of the Royal Society held on May 16th there seemed to be fewer striking exhibits than usual, but there were several of particular interest to those engaged in scientific medicine. Recent advance in microscopic technique were illustrated by Mr. J. E. Barnard in a series of microscopes showing leptospira ictero-hæmorrhagica under different forms of dark-ground illumination. This method has hitherto been of limited value because of the small numerical aperture of the objective employed, but with this new apparatus it is possible to obtain the full value of a numerical aperture of 1.2 with a consequent great increase of resolving power. Dr. Leonard Hill and Dr. A. Eidinow demonstrated the effect of temperature on the biological action of light, showing that the lethal power of ultra-violet rays is manifested much more rapidly at 20° C. than at 10° C. Mr. H. Graham Cannon exhibited specimens of the decapitated water-beetle *Hydrophilus*, on which had been grafted the head of the water-beetle *Dysticus*. One specimen had been dissected to show that complete junction of the cut ends of the oesophagus had taken place. Dr. Hele-Shaw demonstrated the action of a new stream line filter in which fluid is forced between parallel sheets of impervious material which can be regulated at will to produce films of such a degree of attenuation that the matter in suspension can be prevented from entering the interstices between the sheets. From the National Institute of Industrial Psychology, through Dr. C. S. Myers, there came charts illustrating the higher output in coal-mines following improvement in illumination. Coal-miners are unanimous in their opinion that "frosted" lamps afford better vision and less eyestrain. Among other interesting exhibits were those shown by the Department of Zoology, British Museum, of specimens of deep-sea cables damaged by sharks who had fed on the animals growing on the outer casings. The specimens showed the teeth of sharks broken off and embedded in the cables. Another exhibit from the same department consisted of articles removed from the stomach of a man-eating crocodile; they were representative of several human beings, though the reptile's last meal was a porcupine. Mr. F. Harrison Glew's levitating magnet attracted considerable attention. It showed a bar magnet of cobalt steel floating by repulsion above the opposed poles of a fixed magnet. During the evening a demonstration was given by Sir Richard Paget of plasticine models, reproducing the English vowel sounds, and Mr. Walter Heape showed cinematograph films, taken at rates of from 2000 to 3000 per second, of the breaking of an electric bulb, and the behaviour of a rubber ball driven against a solid target.

STERILITY IN WOMEN.

THE question of the ætiology and treatment of sterility in women is one of importance not only to the individual, but also to any State. Certain inquiries recently carried out by gynaecologists in Germany are of more than local interest. Dr. Ludwig Nürnberger,¹ of Hamburg, has recently reported the results of these inquiries. Stress is laid on the importance of establishing a diagnosis of the condition responsible for the sterility before any treatment is

¹ La Pediatria, vol. xxxi., N. 6, 1923.

¹ Deutsche medizinische Wochenschrift, March 30th and April 16th.

commenced, as thereby much time and costly procedures may be saved, both to the patient and to the practitioner. In this respect it is most important to determine the patency of the Fallopian tubes. Excellent results have been reported in the last few years on the use of the passage of gas through the tubes to diagnose their patency. Rubin² reports 67 cases in which he introduced gas into the peritoneal cavity via the uterus and Fallopian tubes, thereby demonstrating that one at least of the tubes was patent. He observed no unfavourable results even in cases of chronic pelvic inflammation, but he does not advise this method in patients suffering from acute inflammatory processes. 250-300 c.cm. of oxygen are sufficient for the purpose, and with this quantity the disturbance to the patient is negligible, and she may continue her daily work after the examination; the discomfort produced by pneumo-peritoneum with larger quantities of gas is entirely avoided. The presence of gas in the peritoneal cavity is ascertained by radiographic examination. It has been shown by Seitz that during the premenstrual, menstrual, and postmenstrual periods, and after parturition the tubes are physiologically impermeable to gas, and therefore the examination must be carried out in the intermenstrual period. The results of these examinations reveal that mechanical obstruction in the tubes occurs much more frequently than was formerly supposed; Seitz and von Graff maintain that no woman ought to be operated on for sterility until the patency of the tubes has been established. Dr. Nürnberger has also used coloured fluid passed through the tubes under pressure from the uterus, and has observed the fluid emerging from the abdominal os during laparotomy. Apart from pure mechanical obstruction to conception, the part played by the internal secretions has of latter years been recognised, and the relation between adiposity and sterility has long been known. Kestner and Plaut³ have distinguished, by means of estimations of metabolism, three forms of adiposity—namely, the pituitary, the thyroid, and the ovarian; further they have shown that the adiposity observed after atrophy of the ovaries or after castration resembles that of the pituitary form, and that therefore it is unlikely that there is a pure ovarian form.

Operative treatment is reviewed under four headings—viz.: (a) Dilatation of the cervix; (b) correction of faulty positions; (c) removal of fibroids, polypi, and repair of lacerations; and (d) renewal of the patency of the tubes. Although dilatation of the cervix is condemned by some on the ground that if the external os is large enough to transmit a red blood corpuscle (7.5μ) during menstruation, it must also be large enough to allow of the passage of spermatozoa (2.3μ), yet in practice it is well known that pregnancy in many cases follows rapidly on dilatation. In the reports received by Dr. Nürnberger there was some difference of opinion on the technique of the dilatation, some authorities advocating simple dilatation, while others combined this with incision of the cervix, and others again used incision only. Several maintained that preliminary dilatation with laminar tents always led to catarrhal salpingitis. The figures of results given are various, and in many cases no figures are quoted, but Reifferscheid reported 17 cases with four successes after dilatation, and 28 cases with eight successes after dilatation combined with abrasion of the cervical mucous membrane. Kehrer had 22 successes out of 48 women treated with tent dilatation. Menge and Fehling emphasise the importance of simultaneously dilating the uterine cavity giving as the rationale for the procedure the view that cervical stenosis is often combined with infantilism of the body of the uterus, and that the mucous membrane is insufficiently developed for the embedding of the ovum. Prolonged packing of the cavity with gauze produces a high degree of hyperæmia, which leads to an increase in the development of the mucous membrane, thereby providing the necessary nidus for

the process of embedding. Corrections of faulty positions of the uterus appear to play but little part in overcoming sterility, and are only undertaken in exceptional cases, for retroversion is either part of a developmental anomaly, or is the result of an inflammatory process, and in either case is not directly the cause of the sterility. Removal of fibroids and polypi and repairs of lacerations show excellent results in cases of sterility (arising in the latter case after parturition). The occlusion of the Fallopian tubes lies usually at the abdominal os, and is not only secondary to gonorrhœal and puerperal infection. It may also follow appendicitis, chronic constipation, and bleeding from a ruptured follicle. Two forms of occlusion can be distinguished—namely, simple closure of the os by adhesions, and closure by invagination of the fimbria, but whether the os is remade by freeing the adhesions or by making a new opening, there is always a danger that reformation of adhesions will occur, and the operative results are very disappointing.

The composition of the vaginal secretion has been much disputed in relation to its hyperacidity and consequent injurious effects on the spermatozoa, but the general consensus of opinion seems to be that alkaline douching has little effect, and that, in fact, as the spermatozoa are usually deposited close up to the cervix, the vaginal secretion can have but little effect on them. Organotherapy has proved useful in cases where the sterility can be traced to a deficiency of one of the internal secretions, of which the ovarian is but rarely at fault. The ovarian insufficiency is often secondary to one of another gland, such as the thyroid or the pituitary. Treatment by various baths is sometimes followed by good results, and massage, diathermy, pelvithermy, and X rays are advocated by some. On artificial fertilisation the questionnaire revealed nothing new. Adverse views are easily explained by the fact that there can be no certainty of bringing a living spermatozoon in touch with a living ovum in the upper genital passages. Practically the only condition in which the practice is permissible is in those cases of abnormality in the male when the spermatozoa are unable to reach the vagina. Dyspareunia may play a great psychical part in the prevention of conception and should be corrected wherever possible.

THE AETIOLOGY OF DEFORMED JAWS.

SOME points in the aetiology of jaw deformities are discussed in an addendum by the assistant school medical officers and school dentists to the annual report for 1922 of Dr. J. T. C. Nash, county medical officer of health and school medical officer for Norfolk. The most common jaw deformities found in Norfolk are (1) narrowing and increase of height of the palatal arch, and (2) undue prominence of the incisor teeth; the former was generally associated with mouth-breathing due to nasal obstruction, and the latter with the use of too much soft food in infancy, and the habit of sucking thumbs, comforters, or "dummies." The most illuminating observations were those of Mr. P. Millican, school dentist. He found a large percentage of abnormal jaws in children living in damp and low-lying places, where the soil consisted of clay, marl, or other impervious beds. Such conditions led to catarrhs and nasal obstruction, mouth-breathing, usually aggravated by enlarged tonsils and adenoids, resulting in mal-development of the floor of the nose and roof of the mouth. Children born and living on high sites or on the sea front were more free from nasal obstruction and consequent narrowed palatal arches than those living in villages lying near the Broads and rivers. Mr. Millican explains that Norfolk is divided into two main sections of geological formation along a line drawn roughly from north to south of the county. On the west of this line is found the chalk; on the east is found a series of strata called the Norwich Crag. This formation is only interrupted by alluvial beds of clay and gravel deposited by various rivers. It

² Jour. Amer. Med. Assoc., September, 1911.

³ Deut. Arch. f. Klin. Med., M. 139, p. 285.

consists of alternate laminations of sands, clays, and pebbly gravels, and is therefore impervious or not always capable of good natural drainage. The chalk, on the other hand, is a pervious rock capable of good drainage. He has noticed a striking difference in the number of cases showing jaw deformity between the children living in the east and those on the west of this line, there being a higher percentage of abnormality on the east side. Thus it was found that the percentage of abnormal palates was under 10 per cent. in some parts and under 15 per cent. in all chalk districts, while it was over 20 per cent. in all the Norwich Crag districts where the soil was clay and under 20 per cent. in only one district where there was gravel. The Norwich Crag only outcrops in the western portion in one place, and covers about three square miles. Most of the children living in this section have abnormal palates. Dr. Nash concludes that Mr. Millican's observations justify placing the probable causes of jaw deformity in Norfolk in the following order of precedence: (1) Locality and environment; (2) habits, "comforters," and thumb-sucking; (3) ignorance or poverty or lack of common-sense on the part of parents; (4) heredity and congenital causes.

MEDICAL EDUCATION IN U.S.A.

WE are kept well informed of the state of medical education in the United States of America. In the *Journal of the American Medical Association* for April 28th were published, for the twentieth consecutive year, statistics based on official reports of examinations conducted by State medical boards, and of registrations by reciprocity and other methods. Increasing support and coöperation from the secretaries of State licensing boards has, during the 20 years, enabled those responsible to make these statistics accurate, reliable, and of great importance in relation to medical education and qualification. The number and qualifications of physicians admitted to examinations, the character of the colleges, the numbers registered and rejected, and the percentages are so arranged that the facts regarding any one college or State can be compared with those relating to other colleges or States. In some States there is evidently satisfactory protection of the public from practice by illiterate and incompetent physicians, whilst in others this protection fails in varying degrees. From the point of view of the prospective student, one table, showing the degree of recognition afforded to diplomas granted by certain medical colleges in States other than their own, is of especial importance. Sixty-one, or 75 per cent., of all medical colleges in the U.S.A. have complete recognition in all States. During the ten years in which this particular table has been published, the percentages of fully recognised colleges has risen from 29.0 to 75.3. Seven other colleges have now against them a few instances of non-recognition due to technicalities in State Medical Board requirements. The diplomas of the remaining 13 colleges are not recognised in from 9 to 47 States. It is evident that graduates of low standard medical colleges will flock to the States where less discrimination is exercised, and these States must remain as fields for inferior medical practice until they adopt more stringent regulations. All States except Colorado now require that applicants must have graduated from a medical school; all States require an examination of all applicants; 47 States have and are using authority to refuse recognition of low-grade medical colleges; 44 States have established reciprocal relations with other States; 10 States require a hospital internship as an essential for the licence, and all but two States—Arkansas and Connecticut—have abolished their separate boards of eclectic medical examiners or have limited their authority. In Connecticut, in 1922, the eclectic board licensed 79 physicians, 39 of whom graduated from low-grade medical colleges, and for 18 no data are found in the official files of medical colleges to show that they graduated anywhere.

The eclectic board not only examined the graduates of eclectic schools, but evidently admitted all others who applied, the Connecticut law to the contrary notwithstanding. In Arkansas, out of 18 candidates licensed by the eclectic board, 17 were graduates of low-grade medical schools. Another problem is that of the licensing of osteopaths, who during the past six years have been admitted to examinations and licensed to practise by a few boards. The objection to this is not that these candidates are osteopaths, but that they are not required to present educational qualifications equal to those demanded of physicians. Inspection shows that osteopathic colleges lack properly equipped laboratories, expert instructors, and clinical facilities, and in the instruction the osteopathic idea is so emphasised that other valuable therapeutic measures are neglected. Despite these serious deficiencies in instruction, 74 osteopaths were licensed as physicians during the year under review. Another table shows that of the 29,338 physicians licensed during that period whose qualifications were obtained in classified colleges, 23,234, or 79.2 per cent., were from Class A medical schools, while only 4202, or 16.7 per cent., were from Class B schools, and 1902, or 4.1 per cent., were from Class C schools. The percentage of those rated in Class A colleges is increasing each year, while the percentages of those from Class B and Class C colleges are decreasing. To sum up: these statistics show for each medical school what improvements are essential if its graduates are to succeed in State board examinations, what State boards are requiring as a minimum of preliminary education, and in what States the boards refuse to examine its graduates. To each State board they show the qualifications of the physician licensed as compared with those licensed in other States, and the further improvements which are needed in its educational standards and methods of examination. Owing to political conditions and other factors, standards in certain States fluctuate considerably; but lessened confusion in licensing is general throughout the country, and continuous publicity has led to a general improvement and a greater uniformity in methods of examination.

CASTRATION OR EPIDIDYMECTOMY FOR TUBERCULOSIS OF THE EPIDIDYMIS?

AT one time, and not very long ago, almost the only operative treatment for tuberculosis of the epididymis consisted of removing the whole testicle. There is much to be said for this operation, which enables the surgeon to avoid incising diseased tissues. But even unilateral castration is a mutilating operation and when, as not infrequently happens, the epididymis on the opposite side becomes involved the surgeon who prefers castration to epididymectomy is likely to rob his patient of very important internal secretions. These and other considerations have led Dr. G. Söderlund¹ to compare the immediate and late results of the two operations, and his statistics deal with the period 1914-20, during which 51 patients were operated on for tuberculosis of the epididymis in a hospital in Gothenburg. In this period unilateral castration was performed in 31 cases and epididymectomy in 24, and in a certain number epididymectomy was first performed, being followed by castration at a later stage in the same case. Dr. Söderlund's preference for epididymectomy is shown by the fact that most of the castrations belonged to the earlier years of the period under review. Only in 20 per cent. of the castrations was the patient discharged from hospital with a fistula, whereas 5 per cent. of the patients on whom epididymectomy was performed still had fistulae on discharge. This eloquent proof of the disadvantages of dividing structures in the neighbourhood of, or involved by, tubercle bacilli. But the ultimate results were if anything in favour of epididymectomy. It was found that si-

² Butterworth and Co. 1923. 15s.

¹ Acta Chirurgica Scandinavica, 1923, vol. lv., fasc. v.-vi.

of the 37 patients who had undergone castration had died within three years of the operation, and six had developed tuberculosis in the epididymis on the opposite side. Of the patients undergoing epididymectomy, 20 were subsequently traced, and of the three who had died, one had died after epididymectomy followed by castration. Only in two cases had the testicle itself to be removed after epididymectomy because tuberculosis had invaded the testicle, and only in two cases were fistulae found in the scrotal scar on re-examination. It is evident from this series of cases that when epididymectomy alone is performed, the chances of the testicle on the same side becoming tuberculous are comparatively small, so small, in fact, that Dr. Söderlund considers they should be ignored when choice is made between the two operations. His most convincing argument, however, on behalf of epididymectomy is that chronic inflammation of the epididymis is often not tuberculous. Yet such benign epididymitis may be clinically indistinguishable from tuberculous epididymitis. In as many as 13 cases in the period under review the diagnosis of tuberculous epididymitis proved, on microscopic examination after operation, to be mistaken. Doubtless, as Dr. Söderlund points out, several of these cases represented benign staphylococcal infections, and would have cleared up of themselves.

PRIMARY CARCINOMA OF THE URETHRA.

THE rarity of primary carcinoma of the urethra, of which Dr. Harry Culver and Dr. N. K. Foster,¹ of the Department of Cystoscopy, Skin, and Venereal Diseases of the Cook County Hospital, Chicago, have recently seen three examples, has induced them to record their observations with a review of the literature. The first case appears to have been reported by Bowin in 1833, since when the writers have collected a total of 120 cases. The incidence is highest in the female sex. The age-period between 40 and 60 appears to be the most susceptible in both sexes. In the female sex carcinoma is undoubtedly an important aetiological factor, although mentioned in only about 10 per cent. of the reported cases. This is especially true of cases which have been frequently cauterised, chronic irritation playing an important part in the malignant degeneration of the tumours. In the male the predisposing causes are trauma, leukoplakia from chronic urethral irritation, and stricture formation, the latter occurring in about 50 per cent. According to Rizzi, the sites most frequently affected are the cavernous (52 per cent.), the bulbous urethra (25 per cent.), and the membranous and prostatic portions (22 per cent.). The onset is usually insidious, and it is not until the growth is well established that pain, disturbance of micturition, and hæmorrhage become prominent. The pain is usually not intense, but radiates into the thigh, pelvis, and vaginal fundus. There is sometimes dyspareunia, especially if ulceration is present. Urinary disturbances are constant, consisting in frequency of micturition, pain in the act, retention, and, finally, complete or partial incontinence. The general condition is not affected until the local process has become very advanced. Three forms of the disease may be encountered: the polypoid or papillary form, the ulcerative, and the infiltrative type. The diagnosis is made by the history, physical findings, and biopsy. In the male the condition must be differentiated from stricture, with extravasation or urinary fistula. The prognosis depends on the stage which the cancerous condition has reached when the patient is first seen and the associated morbid condition. In any event, it is serious, owing to the rapid course of the disease and the danger of recurrence. Treatment consists in operation or the application of physical agents, such as radium or mesothorium. The operative methods employed have been partial resection of the urethra, with suture of the urethral extremity to the mucosa

of the vestibule or vulva, or total resection of the urethra, with the establishment of a neovaginal or suprapubic stoma. Extirpation of the involved inguinal glands has been attempted in ten cases. The use of radium and mesothorium is suitable for inoperable cases. The combination of operation with the use of radium has been effective in some instances. The writers' first case was in a woman, aged 65, who had suffered from pain and frequency of micturition for the last two or three years. Death occurred without operation, and the autopsy revealed primary carcinoma of the urethra, with extensive metastasis to the neck of the bladder and bilateral pyonephrosis. In the second case, which was in a woman, aged 35, the illness was of about seven months' duration, the first symptom being dyspareunia, followed two months later by vaginal protrusion, pain about the bladder, and frequent urination. An elongated, rounded mass was felt in the region of the urethra, extending back into the vagina. The patient was treated with radium, and two months from the last application the general condition was excellent, the pain had subsided, and the bladder was constantly emptied by a vesico-vaginal fistula which had been present for six weeks. The third patient was a man, aged 71, who had accidentally scalded his penis 11 months previously. Three months later he observed a hard growth on the under surface of the organ, and within the last fortnight he had had difficulty and pain on micturition. A diagnosis of primary carcinoma of the urethra was made and confirmed by histological examination after radical amputation of the penis. When the patient was seen six months later there was no sign of recurrence.

ULCUS EPIDEMICUM.

IN a paper read before the Beirut University Pathology Society, Dr. Walter Book Adams,¹ professor of dermatology in the American University of Beirut, remarks that the terms tropical endemic or epidemic ulcers have been used loosely and vaguely for a variety of diseases, such as tuberculosis cutis, syphilis, frambœsia, or oriental button. In the present paper he describes under the name of ulcer epidemicum an epidemic of ulcers which invaded Syria, a subtropical country, during the war. His attention was first drawn to the ulcers in 1916 on the legs of men suffering from starvation œdema, where the sores resembled hospital gangrene in their rapid, shallow, phagedænic growth, the foul odour of the pus, and the difficulty in getting them to heal. In 1917 there were more cases, but fewer of the phagedænic type, examples being found in abundance along the coast from Gaza to Alexandretta. In 1919 the outbreak was prevalent among the poor in inland cities such as Jerusalem, Nazareth, Damascus, Homs, Hamath, and Aleppo. In 1920 there was a marked diminution in the cases, and by 1922 only occasional ones were seen. The ulcers usually appeared in the late spring after the rains had ceased, being essentially a dry-weather disease, and never beginning in the rainy season. They were almost invariably found on exposed parts of the body, the principal sites in order of frequency being the legs, ankles, feet, hands, and forearms. The knees and elbows were rarely affected. The ulcers were usually simple, but occasionally they were grouped. The lesion began as a small itching papule, which rapidly increased in size and became very painful. In one or two days it broke down forming a raw angry ulcer with a sloughing surface, discharging a thick brownish foetid pus. If untreated the lesion became a chronic ulcer, lasting for years with increasingly hard sclerotic edges. Bacteriological examination showed a symbiosis of a fusiform bacillus and a spirillum as in Vincent's angina, associated with numerous cocci. Treatment consisted in stimulating the tissue to a healthy reaction and granulation, and protecting it from further invasion of cocci, flies, and dirt.

QUINIDINE IN AURICULAR FIBRILLATION.

EXPERIENCE is steadily accumulating as to the value of quinidine sulphate in the treatment of auricular fibrillation. Great claims often accompany the introduction of a new remedy which later proves not to meet them, but the specific action of quinidine on the auricle can be demonstrated by graphic records. The dangers of its use were magnified in earlier reports partly because it was then used in more than sufficient doses, and partly because it was tried in unsuitable cases. That it is a valuable adjunct in the treatment of heart disease is becoming steadily apparent, and the observations of Dr. J. G. Emanuel in this issue of THE LANCET add to its position. It is not claimed by cardiologists that quinidine will approach the almost universal application of digitalis in cardiac therapeutics, and we should like to emphasise the fact that digitalis holds exactly as high a place in the treatment of heart failure as ever it did, its employment having become more carefully selective. Indeed, quinidine has no direct value in heart failure, and most of the untoward results are attributable to its use when failure is present. The function of quinidine is to restore the normal regular rhythm to a heart showing auricular fibrillation, and to that extent, and to that extent only, to improve cardiac efficiency. The attempt should be made when failure is in abeyance or when failure has been allayed by digitalis. In a word, digitalis combats heart failure, and quinidine abolishes auricular fibrillation which disposes to failure. Safety is attained if suitable cases are chosen and a moderate daily dose is reached by steps so that an idiosyncrasy towards the drug would be promptly recognised. So guided the danger is slight, but successful results will depend largely upon the care and skill with which the action of the drug upon rhythm is followed day by day during the course of treatment.

METHODS OF SLAUGHTER.

WHERE animals are killed periodically in an enclosed building there would always appear to be an apprehension of death by them. Fortunately the terror can never be so great as that of the human being who is destined to be hanged on the morrow. If fear before slaughter is to be reduced, in the case of animals, to a minimum, the sight, sound, and as much as possible, the smell of death should be hidden from the victims' senses. In other words, each animal should be separately and individually slaughtered. The slaughtering in batches and in sight of each other of pigs and sheep has always appeared to us callous and barbarous. The Jewish method of slaughter, which consists in severing the blood-vessels of the neck with a sharp knife, seems to be quite humane. It has the advantage that the animal is effectively controlled before the method of despatch is brought into operation. Providing the control is carried out humanely, as it invariably is, this mode of killing would appear quite merciful. In Pamphlet No. 2, on the Jewish Method of Slaughtering Animals, published by the Board of Deputies of British Jews, the quoted opinions of 285 veterinary surgeons coincide in declaring that the Jewish method of slaughter is devoid of cruelty. It is true that the majority of these opinions are from German sources, but they are those of practical men of good standing. Most experts agree that the animal becomes unconscious within three seconds after the throat is cut, and the real matter at issue seems to be whether the pain produced by a severe blow that smashes the cranial bones and penetrates the brain is more or less than that produced by a sharp knife making a deep incision. Meanwhile only the introduction of a practicable way of anaesthetising animals before slaughter, non-injurious to the flesh as human food, would satisfy everyone.

THE Croonian Lectures on the Rôle of Fats in Vital Phenomena will be delivered on June 7th, 12th, 14th, and 19th, at 5 P.M., at the Royal College of Physicians of London, Pall Mall East, by Prof. J. B. Leathes.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

XXI.

THE TREATMENT OF ANTE-PARTUM HÆMORRHAGE.

THE first duty when faced with a case of ante-partum hæmorrhage, whether it be slight or severe, is to try to make out whether or not the placenta is attached to the lower uterine segment, since the management of the case after the first hæmorrhage will proceed upon different lines according to the position of the placenta. The determination of this point may be very easy or very difficult. If there have been labour pains and the internal os is open, a partially detached portion of placenta may be felt on passing the finger into the uterus, and this will settle the matter. But if the patient has had no labour pains and is a primigravida, the cervix will be closed and the problem then has to be approached in a different way. No assistance can be obtained from the mode or time of onset of the bleeding, the period of pregnancy, or the character and extent of the first attack of hæmorrhage. Examination of the urine may, however, give valuable help. The differential diagnosis cannot be disposed of in a word and at the first examination the diagnosis must often remain in doubt, but in general terms it may be said that if the head presents and is readily recognised per vaginam, and if the urine contains albumin, the case is almost certainly one of accidental hæmorrhage. If, however, the breech lies below and vaginal examination yields little information, and the urine is normal, the case is probably one of placenta prævia.

Common to both conditions is the need of what we may call for simplicity "hospital treatment"; except in patients of the luxury classes, immediate removal to hospital or nursing home is essential.

Treatment of Hæmorrhage Before Labour.

The immediate treatment of hæmorrhage which is not accompanied by labour constitutes a fairly simple problem. In most cases the first hæmorrhage is moderate in amount and the patient should be put to bed, given morphia (gr. $\frac{1}{4}$ to $\frac{1}{2}$), and detailed obstetric examination should be deferred until the bleeding has ceased. A catheter specimen should be examined and an effort to establish the differential diagnosis should be made.

Accidental Hæmorrhage.—Let us suppose a seven months pregnancy, with head presentation, some albuminuria, and slight œdema of the feet. It is a case of accidental hæmorrhage, the essential factor of which is probably a mild toxæmia. With careful prophylaxis there is an excellent chance that the bleeding will not recur. The patient should be kept in bed and careful eliminative treatment carried out. The diet should contain little protein; diuresis should be produced by drinking large quantities of water, and the bowels should be caused to act loosely twice a day by saline purgatives. The urine should be examined daily, the patient being kept in bed for a week after the bleeding has ceased. Even if no further hæmorrhage occurs special care is required for the remainder of pregnancy, the important points being to secure free action of all channels of elimination and to watch for albuminuria. The prognosis is good. If despite prophylactic treatment, or in cases where this has not been carried out, recurrence of the hæmorrhage occurs without labour, the same treatment should be applied, and the patient kept under close observation for a longer time. Her general condition will probably deteriorate with each attack of bleeding, for apart from the results of loss of blood, there is the toxæmic factor to be considered.

The rare but very grave condition of concealed accidental hæmorrhage probably would never be seen

at all if prophylactic treatment were carried out in all cases after the first attack of bleeding.

Placenta Prævia.—The management of cases of placenta prævia can be sharply distinguished from the above. (1) No prophylactic treatment is practicable, for the bleeding results from a condition entirely out of our control; (2) recurrence of the hæmorrhage is inevitable, and each recurrence tends to be more serious than the preceding one. It follows that we cannot afford to temporise as we may do in a case of accidental hæmorrhage. As a rule it is inadvisable to wait for the recurrence of the hæmorrhage.

Two courses are open in a case of placenta prævia when labour has not begun: one is to induce labour, and the other is to perform Cæsarean section. Cæsarean section is indicated if the patient is a primipara, if the child is alive and of at least 36 weeks' development, and the placenta can be felt all round the margin of the internal os (central placenta prævia). Any one of these conditions taken alone constitutes an arguable case for the Cæsarean operation, but the presence of all three should leave no doubt in our minds whatever. On the other hand, induction should be practised if the patient is a multipara, if the child is dead or non-viable, and if only one side of the os is occupied by the placenta. Again, any one of these conditions taken alone may be held to constitute an indication for induction in preference to Cæsarean section.

The principle underlying these indications is that induction is to be preferred (1) when the local conditions are such as to favour easy delivery (e.g., parity), (2) when the amount of hæmorrhage is not likely to be extreme (e.g., in lateral placenta prævia), and (3) when the child is dead or its survival is already jeopardised by a high degree of prematurity. When the converse conditions are present Cæsarean section allows of rapid delivery, with less hæmorrhage, and a fair chance of survival of the child.

Method of Induction in Placenta Prævia.—Before induction external podalic version may be required, since a breech presentation allows readier control of hæmorrhage during labour than a vertex. For a primigravida with closed cervix the intra-uterine bougie method, performed with strict antiseptic precautions and under anaesthesia, is probably the best. If, however, the patient is a multipara, and the internal os admits the tip of the index finger the decision is not so easy. If the membranes can be felt they should be ruptured with the finger or with forceps. If they cannot be reached and the placenta appears to cover the os completely, it is best to tear through the placenta, perforate the membranes, and pull down a foot into the vagina. This is practicable with one finger only, but is much easier if the cervix will admit two fingers. Traction can then be made in the manner to be described below.

The Conduct of Labour with Ante-partum Hæmorrhage.

Since in most cases the labour is premature, the child's chances of survival are small, and preservation of the mother's life becomes the first consideration. Cæsarean section may be done early in labour when the indications for it detailed above are all present. Generally speaking, however, accidental hæmorrhage is best treated by rupture of the membranes followed by evacuation of a considerable quantity of liquor amnii; placenta prævia is best treated by pulling down the half breech into the cervix after preliminary podalic version if required. In cases of central, or approximately central, placenta prævia rupture of the membranes is not to be recommended, since bleeding is likely to be too severe to be controlled by the pressure of the advancing head. After tearing through placenta and membranes, and pulling a foot down into the vagina, gentle and continuous traction is applied, and labour always proceeds briskly; moreover, the half breech plugs the lower uterine segment and completely controls hæmorrhage. A weight of 2 lb. may be attached to the foot,

but the mother must then be left to deliver herself. Even if the cervix is sufficiently dilated to allow of instant delivery, the temptation to effect this should be resisted, for it is essential that the uterus should have regained its contractility when the moment comes for the delivery of the child. Full use of any interval should be made in the application of restorative measures; in serious cases infusion of blood is the best, but should no donor be available gum saline solution can be used. When the uterus is acting well and the presenting part has passed through the pelvic brim, 0.5 c.cm. pituitrin may be given.

An alternative procedure to podalic version is the use of de Ribes's bag, but in my opinion this is only suitable for cases in hospital when expert aid is always instantly available, and then only under limited indications.

Plugging the Vagina.

Plugging the vagina I regard as a useful emergency measure: (a) As a preliminary to removal of the patient to hospital in an urgent case; (b) in either variety of ante-partum hæmorrhage, to check bleeding while other methods are in preparation. Further, in many cases of accidental hæmorrhage, plugging the vagina combined with previous rupture of the membranes is the method of choice, and no other interference may be required. Further, in cases of concealed accidental hæmorrhage, vaginal plugging combined with active restorative measures, will often give the patient her only chance of recovery.

The technique of vaginal plugging demands a word. Unless it is thoroughly done the bleeding will continue unchecked, and unless the strictest precautions are observed sepsis will follow. The packing must be so carried out that the upper part of the vaginal canal is tightly distended and the cervix completely surrounded by the packing material; a vaginal speculum, a long pair of forceps, and a good light are required, and in primiparae an anaesthetic. When the vaginal vault has been filled, the packing should be pushed upwards with the finger and moulded tightly round the cervix. Unless done in this way it is a waste of time to pack the vagina for hæmorrhage. The vulva should first be shaved and disinfected with iodine or violet green, and the vaginal walls also disinfected. The best material for packing is sterilised "bismuth gauze"—i.e., gauze impregnated with subgallate of bismuth; this can be obtained in 12-yd. lengths of 2 in. wide, and the end of the first length used is tied to the next so as to make a continuous pack. It is expensive but can be relied upon to show no sign of putrefactive changes for 24 hours. A useful domestic substitute is made from long strips of sheeting or tablecloth, cut to appropriate width, and boiled for an hour before use. Packing should always be removed in 24 hours if delivery has not taken place, and some other method of controlling hæmorrhage must then be adopted if necessary. A large proportion of cases in which vaginal packing is adopted in hospital practice show a febrile puerperium, and there is no doubt that the risks of infection which are associated with it are difficult to obviate.

Summary.

1. Prophylactic treatment after the first attack of bleeding is strongly advised in accidental hæmorrhage, but is inadmissible in placenta prævia.
2. Certain cases of placenta prævia are best treated by Cæsarean section after the first hæmorrhage.
3. Cases of placenta prævia in labour are as a rule best treated by podalic version and pulling down a leg.
4. Dilatation of the cervix by de Ribes's bag is not recommended.
5. Most cases of accidental hæmorrhage and certain mild cases of placenta prævia are best treated by rupture of the membranes.
6. Plugging the vagina after rupture of the membranes is useful in many cases of accidental hæmorrhage.

THE CONSTANTINOPLE BOARD OF HEALTH.

A BRIEF HISTORICAL SURVEY.

By F. G. CLEMOW, C.M.G., M.D.,

FORMER BRITISH DELEGATE TO THE BOARD AND PHYSICIAN TO
H.M. EMBASSY, CONSTANTINOPLE.

PART I.

AMONG the innumerable minor effects of the late war must be counted the disappearance of the Constantinople Board of Health—a body which for over three-quarters of a century had directed the Turkish maritime sanitary administration, and had, under the International Sanitary Conventions, been charged with the task of safeguarding Europe from the importation of disease from the East. An institution that, for so long a period, had endeavoured to carry out so responsible a task, may well merit an obituary notice, and the present moment seems an opportune one for giving some account of its origin and history. For, while the Board ceased to exist effectively as an international body after the autumn of 1914, its abolition has not even yet been formally admitted or recognised by the Powers other than Turkey. The question of the future organisation, destined to some extent to take its place, was discussed at length in the first Peace Conference at Lausanne, with results that are still under consideration and cannot, therefore, for the present be made public; but, when the time shall come for their being made known, a right understanding of the problems involved will only be possible if based on a knowledge of their past history. The present survey makes no pretence to be a complete picture of the Board's work—a much larger canvas would be required for any such attempt; it can only lay claim to be a greatly condensed account of the origin of an important sanitary institution and of the methods by which it endeavoured to carry out its international mandate.

The Origin of the Board.

Some obscurity attaches to the birth of the Board, but a study of contemporary original documents has made it possible to piece together the following sketch of its origin and its later developments. The year 1839 has sometimes been given as the date of the Board's coming into existence, but some form of mixed Sanitary Council was unquestionably sitting in Constantinople in 1838. The still earlier attempts of the Turkish authorities to establish a system of quarantine on their frontiers may be rapidly passed over. It is claimed by the Turks that, on the occasion of the great cholera epidemic of 1819, some form of quarantine was applied to ships arriving in the Bosphorus; and that in 1836 a Turkish Quarantine Board, composed of three members, was already in existence. Then, in 1837, mention is found of a Turkish proposal to establish quarantines in the Dardanelles and, in December of the same year, of a further proposal to modify the then existing quarantine laws in Crete. Objections were raised in various quarters—including the Committee of the Privy Council for Trade—to the imposition of quarantines in the Dardanelles except under the strongest necessity.

In April, 1838, the Sublime Porte addressed a circular Note to the heads of missions in Constantinople, formally announcing the intention of the Sultan (Mahmoud II.) to set up a system of quarantines in his empire. Couched in the somewhat flowery language common to proclamations of eastern potentates in those days, the Note stated that His Majesty the Sultan, wishing to calm the fears that "the contagion" (i.e., of the plague), then manifesting itself from time to time in Constantinople, must inspire in the public, had ordained that the system of quarantines should be adopted in his

realms. The mode of applying such quarantines, it was added, was then being considered, and the nature of the sanitary measures decided on was to be indicated in a later communication. On May 19th, 1838, the *Moniteur Ottoman*, the official gazette of the time, published a long article, setting forth in great detail the philosophical and religious reasons for opposing rational measures, such as quarantines, to the calamities with which it has pleased the Almighty to afflict mankind. The article is too long to quote, but it is a document of no little human interest. On May 22nd the Turkish Minister for Foreign Affairs addressed, as promised, a second communication on this subject to the representatives of the Powers. In this the decision to establish quarantines was reaffirmed; the necessity of protecting from contagion, and "if necessary disinfecting" the city of Constantinople was emphasised; cordons and lazarets were, it was stated, to be established; infected places and effects were to be disinfected; cases of plague were to be notified; no dead body was to be buried, no matter what the cause of death, without being inspected by the authorities and a permit given, and so forth. The authority charged with carrying out these measures was spoken of as the "Direction de la Quarantaine," and this appears to have been the earliest public health authority brought into existence in Turkey.

Earliest Regulations of the "Conseil Supérieur de Santé."

On endeavouring, however, to obtain consent to these proposed measures, it at once became evident that their application would be contrary to the Capitulations—under which Turkish officials were unable to visit the domiciles or board the ships of foreign nationals unless accompanied by a consular representative of the country concerned; and this was clearly pointed out in the replies of the Powers to the Turkish Note. In July or August, 1838, some form of Sanitary Council or Health Board was actually sitting, and a British dragoman (Mr. Charles Wood) and others were assisting at its meetings. The council was already spoken of as the "Conseil de Santé," or Board of Health; a little later it became the "Conseil Supérieur de Santé"—and this title it continued to bear throughout the rest of its existence. A draft "règlement" was drawn up by this body in the autumn of 1838, and was considered by representatives of the foreign missions in November. In this document a quarantine of 20 days was demanded even for empty ships; a bill of health was required not only for a ship but for every person on board the ship; a tribunal was proposed for judging cases of infraction of the rules. Ships' manifests, as well as their bills of health, were required to be submitted for examination by the quarantine officials. So strict was the quarantine demanded that it was even proposed to give to the sanitary guards at the lazarets the right to fire on any person attempting to escape. Sanitary offices were to be established at Kavak, near the northern end of the Bosphorus (where a lazaret was actually built later and still exists), and at Gallipoli in the Dardanelles. A temporary lazaret was to be created at Kouléli in the Dardanelles, and certain charges were to be levied on ships until a regular tariff should be drawn up and accepted by the Powers. On land, health officers were to be empowered to enter houses where plague cases existed or were suspected to exist, and to take the necessary measures, if authorised to do so by some member of the Board of Health.

Objections were raised to most of the proposals, more especially to the long quarantines and to the right of sanitary guards to fire on any one attempting to evade them; and it is not clear how many, if any, of the draft measures were actually applied during this period of negotiation—a period which lasted for a considerable time. In the summer of 1839 a fresh effort was made by the Turkish Government to obtain acceptance of its proposals—to which had now been added one to the effect that that Government should

be authorised to adopt and put into execution the sanitary measures, but that these measures should first be suggested by the foreign delegates to the Board. A "Règlement Organique pour les provenances de mer" was drawn up, and signed on June 10th, 1839. The preamble to this Règlement is of sufficient interest to be quoted in full; it is as follows:—

"Les soussignés composant, d'une part, le Conseil de Santé sous la présidence de S.E. Hifzy Moustapha Pacha, de l'autre la délégation étrangère accréditée par les différentes missions, à la demande de la Sublime Porte, près ledit Conseil, s'étant réunis en conférence à l'effet de délibérer sur le choix de système quarantenaire le mieux approprié à cette Capitale contre les provenances de la mer, animés d'un égal désir de concilier, autant que possible, les garanties sanitaires avec les besoins de commerce maritime, ont, après mûre délibération, arrêté de commun accord les résolutions suivantes: (Then follows the text of the regulations)."

From this it is clear that the presence of foreign delegates on the Constantinople Board of Health was brought about at the request of the Turkish Government itself. The regulations contained 19 articles, and one "additional article." It is interesting to note the resemblance of the problems that had then to be faced to those with which sanitarians in the Near East are still confronted. Ships were then, however, as for many decades after, dealt with according to their bills of health and not to the actual state of the ship. Bills of health were either "clean" (*net*), "suspect," or "foul" (*brut*); the corresponding flags to be hoisted were white, black and white, and black. A bill of health was "clean" if delivered 30 or more days after the last case of plague in the port of departure, and such ships received immediate pratique. A "suspect" bill of health was one delivered between 15 and 30 days after the last case; such ships had to do 15 days of quarantine if loaded and 10 if empty. A "foul" bill was one delivered less than 15 days after the last plague case, and for such ships a quarantine of 20 days, if loaded, was required, and 15 days if empty. Ships of the last two categories were required to take on sanitary guards at the Dardanelles or at Gallipoli, if passing up the Straits, and at Kavak if passing down; and only empty ships were allowed to pass the Straits and proceed "en quarantaine." The maximum quarantine for goods was 20 days. Infractions of the regulations were to be judged by the laws in force in European countries, and the offender was to be handed over to his own authorities for punishment. A sanitary tariff was annexed to the regulations, setting forth in detail the taxes to be charged for bills of health and for the "interrogatoire"; the quarantine dues on ships, on persons and on animals; and the charges for disinfection of goods. Ships of war were exempted from all sanitary charges.

This document, it is of interest to note, bore the following signatures: A. Pezzoni, Ed. de Cadalvène, Ant. de Raab, F. Bosgiovich, J. Bosgiovich (delegates); Hifzy Moustapha Pacha (president); Drs. Minas, MacCarthy, Neuner, Bernard, Marchand, and G. Franceschi (members of the Board). It will be observed that not only the delegates but also the members of the Board were, with the exception of the president, of other than Turkish nationality, and for a very considerable period Turkey herself provided no medical member of the Board. About this same period the question of overland quarantines was discussed and regulations were drawn up; but the death of Sultan Mahmoud II., on July 1st, 1839, seems to have led not only to this question being dropped, but also, apparently, to a considerable diminution in the activities of the Board of Health and the quarantine authorities.

The minutes (*procès verbaux*) of the Board—destined in the course of three-quarters of a century to fill some hundreds of large volumes—begin only with the meeting held on Feb. 10th, 1840. The minutes of that meeting fill but half a page of a folio volume. It was not until the "35th meeting," held on August 28th, 1840, that any signatures were attached to the minutes, and it is of interest to note that among the signatures

of those present at that meeting (held 83 years ago) occurs that of Dr. E. D. Dickson, who appears to have been at first intermittently and later permanently the British delegate to the Board until his death in 1900—the year in which I had the honour to succeed him in that capacity and as physician to H.M. Embassy.

The Powers represented on the Board in 1840 were apparently the five Great Powers, Sardinia, and Greece. For the first few years the Board contended against many difficulties and much opposition on the part of the Turkish Government. The latter seems to have regretted having created the institution and to have made considerable efforts to reduce its powers to a nullity or even to break it up altogether. In 1844 the president is said to have attempted to exclude the foreign delegates entirely and to make what remained of the Board "dependent upon his arbitrary pleasure." On the initiative of the British Ambassador, Sir Stratford Canning, the heads of missions in Constantinople made strong representations to the Turkish Government as to its unsatisfactory attitude towards the institution and, as a result, the arbitrary proceedings of the president were checked, and it was agreed that all questions—whether they related to the appointment of medical or other officials or to the administration of the quarantine department—were to be decided by a majority of votes in the Board of Health. Further, a Turkish official in the confidence of the Porte and properly qualified for the task was appointed to take part in the discussion with the delegates and the other European members of the Board.

Such, briefly, was the origin of the composite body which was destined to direct sanitary affairs on the coasts and frontiers of the Turkish Empire for a period of some 75 years—until, indeed, the outbreak of the Great War in 1914. Space will not permit of a detailed account of its history throughout that long period. It passed through many vicissitudes, and at one critical moment of its history, when its action met with the disapproval of the reigning Sultan, the latter threatened to swamp it by the nomination of a large number of Turkish members, sufficient to outvote the foreign element on the Board—a threat analogous to that made a few years ago to a more august body in this country. Throughout the later decades of its existence the Board was composed of eight Turkish members and a varying number of foreign delegates, reflecting the political changes in Europe during that period. At the moment of its extinction in October, 1914, the foreign delegates numbered 13, representing the following Powers: Austro-Hungary, Belgium, France, Germany, Great Britain, Greece, Holland, Italy, Persia, Russia, Spain, Sweden, and the United States of America. Norwegian interests were entrusted to the German delegate.

On May 27th, 1840, a second and more extended "Règlement Organique" was adopted, prescribing the sanitary measures to be enforced, but no similar code defining the composition, attributes, and powers of the Board was ever drawn up. These were, however, gradually more or less clearly defined by means of another international body, of which more will be said later—the Mixed Commission for Revision of the Ottoman Sanitary Tariff. The tariff annexed to the 1840 "Règlement" remained in force until it also was modified by the Commission just named.

Extension of the Work of the Board.

It will be seen, from what has been said above, that the Constantinople Board of Health was originally a local body, brought into existence to meet the immediate menace of a plague epidemic and limiting its aims mainly, if not entirely, to the protection of the Turkish capital. It only later extended its work to the protection of the other ports and frontiers of the Turkish Empire and gradually assumed the many other responsibilities that fell to it during the later decades of its existence. Though it had, as has been shown, a semi-international character from its very

beginning—as regards its composition at least—it was not until some 13 years after its creation that it received any definite international mandate from the Powers in general. But it received that mandate from the earliest moment that the Powers came together in a sanitary conference, and were thus in a position to make any joint utterance on international sanitary matters; and the mandate was confirmed and enlarged by the subsequent Conferences and Conventions. Thus the first International Sanitary Conference, that of Paris, 1851, specifically charged the Board with the execution of sanitary measures in the Turkish Empire, and authorised it to fix the places where such measures would be applied; to publish regulations, based on the Convention; to appoint and dismiss its personnel, and so forth. It required that the foreign delegates on the Board should be appointed by their respective Governments, and should be “as far as possible specialists.” Similar clauses appeared in the (abortive) Paris Convention of 1859. The third Conference, that of Constantinople, 1866, while mainly dealing with cholera from the scientific point of view, incidentally discussed the financial affairs of the Board, as will be shown later. The Vienna Conference of 1874 scarcely mentioned the Board; that of Washington of 1881 was concerned only with yellow fever; the Rome Conference of 1885 was not followed by a Convention; and those of Venice, 1892, and Dresden, 1893, did not deal with the Board's affairs. But the Convention of Paris, 1894 (as also the three later Conventions), prescribed that all pilgrim ships entering or leaving the Red Sea should comply with a “special ordinance applicable to the pilgrimage to the Hedjaz,” to be published annually by the Constantinople Board of Health in accordance with the principles laid down in the Conventions, and this practice was followed by the Board. It further required that the supervision of these measures should be entrusted to a committee, chosen from the Board and to consist of three Turkish members, and of representatives of Powers that had acceded or should accede to the Conventions of 1892, 1893, and 1894. This latter clause was not strictly adhered to; it was, however, the practice of the Board to elect each year a Pilgrimage Committee, composed of one or more Turkish members and of delegates representing the Powers most interested in the Mecca pilgrimage. That committee revised each year the “special ordinance” and endeavoured (rarely, it must be admitted, with complete success) to make it conform in every detail with the pilgrimage clauses of the later Conventions.

The Venice Conference of 1897 was concerned with the serious danger to Europe arising from the outbreak of plague in India and more especially with measures applicable to pilgrim ships. The Convention that followed contained detailed recommendations for the reorganisation of the great lazaret of Camaran (Turkish) and of those of Abou-Saad (Turkish) and El Tor (Egyptian). In this Convention measures were for the first time prescribed for the sanitary protection of the Persian Gulf, and the Constantinople Board was charged with their execution, and with the reorganisation of the sanitary defences of the Turco-Russian and Turco-Persian frontiers. The Paris Convention of 1903, while again confirming the general mandate of the Constantinople Board, contained important clauses prescribing the composition and attributions of the Board, the reduction of the Turkish members from eight to four, and so forth. Unfortunately most of these clauses were not accepted by Turkey, and therefore remained inoperative; they were completely eliminated from the last Convention, that of Paris, 1912. The Conventions of 1894, 1897, and 1903, however, confirmed the financial arrangements of the Board, which are referred to in more detail below.

But there were other duties, not specifically mentioned in the Conventions, which the Constantinople Board was called upon to discharge. It had the sanitary supervision, not only of the great pilgrimage to the Hedjaz, but also of the Shiah pilgrimage and

carriage of dead bodies to Kerbela, Nejef, and the other Shiah holy cities in and near Mesopotamia. Further, although the Board's mandate was in principle limited to the coastal and frontier defences of the Turkish Empire—the interior sanitary defences being in the hands of the Turkish authorities—a special exception was made in the case of the Hedjaz Railway (connecting Damascus with Medina), and for some years before the war the sanitary defences of that line had been provisionally entrusted to the Board until some more permanent arrangement should be come to.

It will be seen, then, that the Board's responsibilities were by no means light. Its mandate covered an immense geographical area—extending from the Turco-Persian and Turco-Russian frontiers on the east to the Albanian coasts of the Adriatic on the west; from the Black Sea coasts of Asia Minor on the north to the shores of Tripoli in Africa and the Arabian coasts of the Red Sea on the south; and including such varied conditions of population, climate, race, and religion as are (or were) to be found in Arabia, Mesopotamia, Asia Minor, Armenia, Syria, Palestine, Crete and the Aegean Islands, Tripoli and the Cyrenaic peninsula, Thrace, Macedonia, and Albania; while in former years it embraced such additional trifles as the territories that have since become the independent states of Bulgaria, Roumania, and Serbia.

(To be concluded.)

(FROM OUR OWN CORRESPONDENT.)

The Suppression of Abortion.

THE Chamber of Deputies has adopted a Bill modifying the provisions of Article 317 of the Code Pénal with reference to abortion. Henceforward, whoever, by the administration of certain foods or medicaments, or by manipulation, violence, or any other means, shall have procured or attempted to procure abortion in a pregnant woman, with or without her consent, will be liable to imprisonment for from one to five years, and to a fine of from Fr.500 to Fr.10,000. A woman who has procured abortion on herself, or who has consented to use the methods indicated to her for this purpose, with the result that abortion takes place, will be liable to imprisonment for a period of from six months to two years, and to a fine of Fr.100 to Fr.2000. Doctors, health officers, midwives, surgeon-dentists, pharmacists, as well as medical students or employees in chemists' shops, herbalists, and sellers of surgical instruments, who have indicated, recommended, or practised these methods, will be condemned to the penalties set out above. Those found guilty may, besides, be temporarily suspended or permanently prohibited from practising their profession, according to Articles 25 and 26 of the law of Nov. 30th, 1892, which articles in this connexion are applicable to qualified pharmacists and herbalists, as well as to those aspiring to diplomas. Besides the penalties mentioned, the courts may forbid the person found guilty from residing in a stated neighbourhood for a period of from two to ten years.

It is, unfortunately, to be feared that even the maximum penalty of 10,000 francs and five years imprisonment will still be insufficient to prevent the crime of abortion. Recently a girl, Inda Kriginold, and her lover, Benjamin Kotlar, both Russian subjects and students of medicine, were arrested; they had an excellently equipped consulting room, most comfortably furnished and fitted with all necessary apparatus for preserving the strictest asepsis. They had been practising for many years, and were responsible for over 1000 abortions. In view of the danger to the future of the country, it may be hoped that heavy punishment will be meted out to criminals of this type.

Scottish Medical Students in Paris.

The Scottish medical students at present in Paris were recently received by the Association Générale

des Etudiants, who are now housed in the old Faculty of Medicine. A soirée was organised in honour of the visitors, and was presided over by Mr. Roger, the Dean of the Faculty of Medicine. The day before a trip to Versailles was organised, to which both French and Scottish students were invited, and proved an excellent means of promoting friendliness among the two batches of students.

Neurological International Reunion.

The fourth annual Neurological International Reunion will be held on June 8th and 9th, in the amphitheatre of the Ecole des Infirmières, at the Salpêtrière. The sessions will take place in the mornings from 9 to 12, and in the afternoons from 3 to 6. The main subject discussed will be medullary compression. Those reading papers include Sir James Purves Stewart and Dr. George Riddoch, of London, on the Pathological Anatomy and the Pathogenesis; and Mr. Ch. Foix, of Paris, on the Physiology, Clinical Pathology, and Therapeutics.

Pasteur Centenary.

The programme of the fêtes arranged to celebrate the Pasteur centenary are as follows. Foreign delegates will be received at the Elysée on May 24th. In the morning of May 25th a visit will be paid to the Institut Pasteur and the tomb of Pasteur. In the afternoon a ceremony will be held at the Sorbonne, under the presidency of Mr. Millerand. On May 26th a visit will be paid to the Ecole Normale, and in the afternoon a reception will be held at the Hôtel de Ville. On Sunday, May 27th, various societies will receive the delegates, and in the evening gala nights at the Opéra and the Théâtre Français have been arranged. On May 28th a banquet will be held at Versailles, and on the 29th a garden party will be organised at Chantilly by the Institut de France. On May 30th the delegates will repair to Strassburg. On May 31st the monument to Pasteur will be unveiled, and after a banquet lunch the Pasteur Museum and the hygiene exhibition will be opened. In the evening a reception will be held at the Hôtel de Ville.

The Medical Service of Paris at Night.

Visitors to Paris would do well to acquaint themselves with an organisation for medical emergencies at night provided by the police authorities for strangers, persons without a regular medical attendant, and others. This organisation has existed for some time, and a recent inquiry into its working by *L'Echo de Paris* has proved it to be run in a very satisfactory manner. This is the more creditable as the difficulties in making the machinery work smoothly were at first considerable. "Le Service Médical de Nuit" is available for everyone, and when the family doctor is out of town, or the patient does not wish to disturb him and is anxious to avoid delay, application is made in person or by telephone to the nearest police station. A telephone message is sent from the station to headquarters, where one or more of the staff of 30 doctors are on duty from 10 in the evening till 6 in the morning. The doctor proceeds at once in a motor with emergency appliances to the address given him, and it is seldom that the interval between sending for the doctor and his arrival is more than 20 minutes. If he desires to write a prescription, this is taken to the police station, whence a cyclist takes it to a chemist and brings back whatever has been prescribed to the patient's house. The charge for such a night visit is fixed at Fr.20, but this fee may be reduced if, on inquiry, circumstances warrant such a reduction, and in case of extreme poverty the fee is waived altogether. At first this night service was limited to doctors under the age of 30, but there is now no age limit, and the doctors on the staff take duty in rotation. The average number of calls per night is 30 to 35, and it is evident that this system is a boon not only to patients, but to doctors who, having had a long day's work, have richly deserved an uninterrupted night's rest.

May 17th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Midwives Act.

THE law recently passed concerning the training and practice of midwifery provides that, apart from the medical profession, only trained midwives are entitled to deal with parturition and childbed. Their training will extend over 18 months, and must be practical as well as theoretical; it will be carried out at one of the public midwifery schools which exist in every province. During her training a candidate must attend at least 50 parturitions; admission to a training school is made dependent on a certificate of health and good conduct, and a person applying for admission must be at least 20 and not more than 30 years of age. After practical training a candidate must pass a theoretical examination in the physiology and pathology of pregnancy, parturition, and childbed, and in the care of newborn children. The practical training includes the diagnosis of abnormal cases; if the latter are not available at the time of examination the candidate must prove her knowledge on an anatomical model. A midwife being qualified after examination may not live where she likes, as has hitherto been the case; the law provides for distribution of midwives according to the wants of the population. In places where they refuse to settle the Government may eventually appoint district midwives at a fixed salary. The law provides for a scale of fees graded according to the wealth of the mother, the minimum fee being payable by poor persons and club patients. A minimum income is guaranteed to midwives, and when fees paid by patients do not reach that minimum the balance is to be covered by the Government. The midwife must summon a medical man in every abnormal case, and if the mother and her family refuse she must decline all responsibility, ask for a certificate stating that she wishes a medical man to be summoned, and report the refusal to the district medical officer. Cases of puerperal fever must be notified at once to the district medical officer, and for the duration of that case, and for some time afterwards, the midwife must abstain from work with other mothers under constraint of heavy penalties. Each midwife must keep a register, which will be checked by the district medical officer, who is empowered to examine the midwife's knowledge every second year. The midwife must attend a three weeks' post-graduate course every five years in a provincial training school; if she fails to do so without a reasonable cause her qualification may be withdrawn. The qualification may also be withdrawn for grave misdemeanour and unprofessional conduct. The law provides for the institution of district midwifery boards—to consist of two midwives, two mothers, and female representatives of the sick clubs, under the chairmanship of the district medical officer—and also of provincial midwifery boards. Rather curiously, the law defines the term "mother" as "a woman having borne at least one living child." The most important alterations brought about by the new law are the creation of a definitely professional body of midwives, and the granting of a minimum income.

Proposed Settlement of German Medical Men in Afghanistan.

The Afghan Government has invited German medical men to settle in that country, offering a salary of £15-25 a month, to be reduced to half in cases of illness. The Afghan authorities declared that a medical man only requires £5-6 to keep him, and that he would thus be able to save the rest of his salary. In the *Aerztliche Mitteilungen*, the official organ of the German Medical Union (Leipziger Verband), a correspondent states, however, that the minimum expenses necessary for a professional man in Afghanistan range from £15 to £25 a month, so that a medical man earning the sum offered would be unable to save. The correspondent compares

the salary offered with that granted to officers of our Indian Medical Service.

Cocainism in Germany.

The abuse of cocaine has greatly increased since the war. Formerly it occurred almost exclusively among persons having easy access to the drug, such as druggists, workers in chemical factories, and sometimes medical men. In a recent discussion at the Berlin Medical Society it was stated that the cocaine habit has now invaded nearly every class of the population, and to a greater extent than the morphia habit. Cocaine is snuffed, and is thus easier to take than morphia, which requires injection; it also produces more agreeable sensations. The habit has been further spread by the numerous Russian emigrants now settled in Berlin. Cocaine may not be sold without a written prescription from a medical man or dentist, but it is sold clandestinely, especially by waiters and attendants in certain restaurants patronised by the demi-monde. Great masses of cocaine were stolen after the war, during the revolutionary period, from the Government stock kept for the use of the military hospitals. The production of cocaine is now only allowed in certain factories under Government control (where it is not manufactured from raw cocaine, which may be misused, but extracted by a very complicated chemical process from coca leaves brought from Java), and import of the drug from abroad is strictly licensed. It was argued in the discussion at the Berlin Medical Society that these measures were not sufficient to suppress the evil; that people, especially those living in large towns, wanted stimulants, and that coffee, tea, tobacco, and beer were very expensive compared with cocaine, of which only a small quantity was necessary to produce intoxication. Thus, when the prices of other stimulants were lowered, the abuse of cocaine would be greatly reduced. It was, however, also stated that the majority of persons indulging in cocaine do not do so for reasons of economy, but that they are for the greater part psychopathic subjects unable to face the difficulties of the present hard times without a drug.

Public Health in Prussia.

The Prussian Minister of Health in a recent report to the Prussian Parliament on the state of public health in Prussia stated that diseases of the bronchi and lungs have greatly increased as a result of the scarcity of fuel. Tuberculosis, which showed a constant decrease before the war, has again increased enormously, the number of deaths recorded being 56,000 in 1913, 110,000 in 1918, 78,000 in 1920, and 83,000 in 1921. Since 1918 12 per cent. of hospitals, 15 per cent. of infants' homes, and 15 per cent. of public dispensaries have had to be closed for want of means; the supply of food to hospital and other patients has become inadequate, and other hygienic measures have had to be abandoned. The attention of the Government was especially drawn to the state of health of the children; the general underfeeding of the children which resulted on the blockade can never be made good, and although when the blockade was lifted an improvement occurred, especially with the help of the Quakers, the cost of food is now again productive of distress. In many schools, according to the reports of school medical officers, 50 per cent. of children are underfed, and in some Berlin schools 20 per cent. of the children have had to be temporarily exempted from attendance on account of anæmia and general weakness. Those coming to school have often had no breakfast. The deficiency of linen and soap, and the expense of baths, make proper care of the body very difficult, and diseases of the skin are frequent. Many school-children have no shirts, or are compelled to wear the same shirt for months. Deaths due largely to hunger have been reported in several districts—230 cases in one district alone. Scurvy, before the war almost unknown in this country, occurred in 36 cases, of which 10 were fatal.

May 12th.

CONGRESS OF THE ROYAL INSTITUTE OF PUBLIC HEALTH.

It is perhaps a sign of the widening view of what constitutes public health that the President of the Congress, Lord Riddell, at the inaugural meeting in the Grand Hall of the Spa at Scarborough chose for the theme of his address the problem of capital and labour. He gave an impartial survey of the changes during the last 25 years. Labour, which was then concerned with wages, hours, and conditions, now claimed to take a part in the management of industry and the reconstruction of the State. "The group mind," said Lord Riddell, "gives no indication of becoming more altruistic. It behoves every man and woman to take an interest in a question of such vital importance to the future of the country."

The business of the Congress began on May 17th in five sections.

Section of State Medicine.—At the meeting of this section Sir William Middlebrook, M.P., traced the development of municipal work, which, he believed, had not yet reached its full height of activity. Mrs. Edwin Gray (York) spoke of the place of the voluntary worker in public health, and stated that suspicion and jealousy were gradually disappearing with the practice of working in water-tight departments. Dr. J. R. Kaye (M.O.H., West Riding) introduced the housing question. He gave some deplorable examples of overcrowding, and estimated that at least 45,000 houses were needed at once in the West Riding alone.

Women and the Public Health Section.—Lady Dorothy Wood, in her presidential address, stressed the need for creating an enlightened public opinion. Dr. Jane Walker (East Anglian Sanatorium) dealt with the prevention of consumption, and expressed the opinion that although food, milk, and housing were important, tuberculosis was largely an industrial disease. Dr. H. Scurfield, in agreeing, hoped in future more prominence would be given to the sex death-rates in industrial towns, as this would bring out more clearly the effect of occupation in causing consumption. At the afternoon session the milk problem was dealt with by Mr. Wilfred Buckley, Dr. Eric Pritchard, and Dr. Scurfield. The trend of the papers was that the extension of the movement for "tubercle free" milk would only be slow, and that in the meantime pasteurised milk and good brands of dried milk were safe substitutes, little, if any, inferior in food value, which had certainly played a part in the recent remarkable decline in infant mortality.

Industrial Hygiene Section.—Sir Lynden Macassey presided over this section, and welcomed the fact that employers were beginning to coöperate with the Industrial Fatigue Board, and were inviting the active assistance on a business basis of the National Institute of Industrial Psychology. Sir Thomas Oliver gave an address on the Health of the Worker a National Asset, dwelling on the extraordinary variations in the percentage of fitness among the workers of different districts revealed by the recruiting statistics. There was great need for an improvement, not only in housing conditions, but also in the ventilation, &c., of factories. He further advocated a better and more uniform system of recording sickness in our large factories and of standardising the records.

Other Activities.—Lieut.-General Sir Arthur Sloggett presided over the Naval and Military, &c., Section, and Dr. Frederick W. Twort over the Section of Bacteriology and Biochemistry. In a popular lecture Dr. C. W. Saleeby urged the claims of sunlight, and said our industrial cities showed the most appalling contrasts in respect of light-starvation with the cities of Germany, Switzerland, Canada, and the United States. The thing to do in the interests of childhood was to restore the sunlight to our towns, which were the blackest on earth.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following table gives some of the principal statistics for 1922 of four towns varying considerably in position, population, and types of inhabitants.

Name of district.	Estimated population (mid-year).	Birth-rate.	Death-rates per 1000 of population.				Death-rates per 1000 births.		
			All causes.	Tuberculosis.	Cancer.	Respiratory with influenza.	Infant mortality		Maternal mort. in childbirth.
							Legit.	Illegit.	
Bootle C.B. . .	79,750	25.7	13.7	1.6	0.8	3.6	75	234	3.4
Edmonton U.D. .	68,700	22.1	10.8	1.0	1.2	2.2	67	125	3.3
Stoke Newington M.B. . . .	52,620	17.8	12.9	0.9	1.2	3.5	—	—	5.3
Margate B. . .	27,820	17.0	11.6	0.9	1.6	1.9	59	29	4.2

C.B., County Borough. M.B., Metropolitan Borough. B., Borough. U.D., Urban district. Where a short line is given the figure is not available from the report.

Bootle.

Dr. F. T. H. Wood reports a sharp outbreak of influenza from mid-January to mid-March with a particularly heavy incidence among young children. The elementary schools were closed from Feb. 1st to 10th and steps were taken under the Bootle Corporation Act to close Sunday schools and to exclude children from cinema halls and places of entertainment. A new pavilion of 28 beds for advanced cases of tuberculosis at the Linacre Hospital was opened in May. The Corporation maintain six beds at Leasowe Hospital for children suffering from non-pulmonary tuberculosis, but provision is needed for adult cases, who need surgical treatment. The municipal maternity home was opened in February. Sixty-nine patients were admitted. The regular charge is six guineas for a fortnight. The actual charge averaged £4 2s. per patient. The cost to the rates, after deducting contributions and grant, for the year ending March 31st, 1923, was £571. Public health educational work is being undertaken in earnest and a successful "Health Week" was held in October. The municipal housing scheme has now come to an end with the completion of 302 houses. Originally two sites were purchased and it was intended to erect 314 houses on site 2 and 280 on site 1. Now part of site 1 has been allotted to the educational authority for a school and site 2, under instructions from the Ministry of Health, has been offered for sale. Dr. Wood says there is some diminution of the more serious overcrowding by the completion of 200 houses during the year, but he points out that the excess of births over deaths during this period was 958.

Edmonton.

Dr. H. W. Harding reports that diphtheria continued to be prevalent for the first quarter of the year and that chronic nasal carriers gave trouble. Three of these carriers had their tonsils enucleated and one was benefited by a diphtheria vaccine. The Schick test has not been used, but Dr. Harding is a believer in swabbing, and the routine practice of swabbing diphtheria contacts is adopted. The ante-natal clinic has become very popular. A cleansing station, including bathrooms, a shower spray for dirty heads, and electric fan for driving warm air for drying the hair, a formalin chamber for leather goods, &c., was added to the equipment of the school medical department during the autumn. All cases of tonsils and adenoids are freed from oral sepsis by dental treatment before operation. Operations are performed

at the North Middlesex Hospital. A fee of 10s. is charged and 5s. extra if the case is kept for the night on medical grounds. After operation the cases are conveyed home in the Council's ambulance with a nurse in attendance. The value of the dental scheme has been increased during the year by the appointment of a dental anaesthetist who holds both dental and medical qualifications. Dr. Harding would like to see more differentiation between the backward and the mentally defective children for educational purposes. "It does seem curious," he says, "that a sum of £50 per year can be spent on a mental defective who at the age of 16 is turned adrift to follow his own resources and that no special provision is made for the dull child, who, by his natural intelligence, will probably make good in later life." Dr. Harding reports that the housing problem is still a serious one in Edmonton.

Stoke Newington.

Dr. H. R. Kenwood gives some advice as to cancer, emphasising the need for avoiding sources of prolonged irritation. The "danger signals" of cancer are clearly set forth and the fact that lives could be saved if people would attend to these danger signals and seek early medical advice. At the end of the year Dr. Kenwood investigated the home circumstances of 40 "open" cases of pulmonary tuberculosis. Twelve of them occupied bedrooms shared by from one to three children under 12 years of age. He would like to see provision for the removal either of the cases or of the children, and thinks that resident institutions for such children would be one of the wisest provisions that could be made for checking the onslaughts of this disease. A dental clinic is badly wanted in connexion with maternity and child welfare work. A notable feature of the southern portion of the borough is the "tenementation" within recent years of houses originally built for and occupied by one family. Industrial development of Stoke Newington is unlikely to occur, but there is an urgent need of more dwellings to reduce the excessive occupation of many existing ones.

Margate.

Dr. Rowan McCombe reports that ten cases of enteric fever were notified and that half the patients had eaten freely of cockles. He says that these shell-fish are supposed to be treated by steam for a sufficient time to kill any harmful bacteria before being sold to the public, but since this process tends to destroy the flavour and harden the fish sterilisation is often skimmed or neglected. The meteorological report shows a great contrast to that of last year. The hours of sunshine were 1562, compared with 1800, and the rainfall was 20.5 inches, compared with 9.28 inches.

SCHOOL MEDICAL SERVICE.

Hull.

THE school medical officers in Hull paid 1189 visits to schools and examined 20,513 children, including 5399 special cases. The number requiring treatment or special observation was 5793. The vision and hearing of 5672 children between the ages of 6 and 7 years were estimated by means of test types and the whisper test—the latter a test extremely difficult to carry out in an ordinary school with any degree of accuracy, and the result is not recorded. The vision test of these children discovered 5.6 per cent. with defective vision—that is, with vision of less than 6/12, this figure being the same for boys and girls. Dr. J. W. Fraser states, "the vision of boys improves from code group to code group, the cases of defective vision being only 4.1 per cent. at 8 to 9 years, and 3.8 per cent. at 12 years; among girls there is a slight deterioration, the cases of defective vision being 6.7 per cent. at the 8-9 year period and 6.5 per cent. at 12 years." One cannot question the accuracy of these deductions as the numbers dealt with are not supplied, but it must be remembered that in testing the vision of the younger children with the ordinary Snellens test type there is a considerable mental factor which cannot be ignored.

Unfortunately an outbreak of diphtheria of such severity as to make it necessary to close the school obtained for five weeks. Out of 788 swabs 158 gave positive results and 16 developed clinical diphtheria. An especially interesting feature of this report is the section devoted to special schools. Great care has been taken to find out the after-results of the special care taken of these children. In the last ten years 34 persons (18 male and 16 female) left Osborne-street special school for deaf children. These have been followed up, and the result given (Table I.).

TABLE I.—*Number Employed; Earnings per Week.*

	Boys.				Girls.			
	Un-paid.	Less than 20s.	20s. to 40s.	More than 40s.	Un-paid.	Less than 20s.	20s. to 40s.	More than 40s.

(d)	—	—	1	—	—	—	—	—
(e)	—	1	—	—	—	—	—	—

(a) Industrial or manual occupations. (b) Agricultural and rural occupations. (c) Domestic occupations. (d) Commercial or clerical occupations. (e) Precarious work.

Two—one of each sex—are incapable of employment on account of deafness, 1 girl has died, 1 girl has left the city, 3 girls are now married, 1 boy has been employed and is now out of work, and 1 boy is in another institution.

The after-careers of persons discharged from the special school for mental defectives are naturally different. Of 166 children who have left the Malton-street special school for mentally defective children since 1912, 12 have died, 27 are incapable of employment on account of mental defect, 32 are in residential institutions for mentally defective persons, 10 are in other institutions, and 16 have left the city or cannot be traced. Table II. shows the earning capacity of those employed.

TABLE II.—*Number Employed; Earnings per Week.*

(a) to (e) as Table I.

Dr. Fraser points out that if a similar number of mentally defective persons all over the county are given residential treatment, the number of institutions required and the expense incurred will be very large; but against this, he says, must be set off that, in a well-managed institution, each inmate does something towards his support and any chance of children being born to inherit the parental defect is prevented.

As Park-avenue special school for crippled children was opened as recently as 1920, it is impossible to get out corresponding returns for the cripples, but substantial progress in school work and medical treatment is reported. The school has 69 children on the roll, 41 of whom are here as a result of infantile paralysis, and there are 12 cases of tuberculous disease. The superintendent spent a month at the Cripples' Hospital at Alton during the year with excellent results, and the children are now making their own splints. Forty cases have massage and 35 electrical treatment daily. The children are happy, and their health throughout the year has been good.

Leeds.

The school medical officer here is assisted by seven full-time doctors, three part-time specialists, and a

whole-time nursing staff of 26 nurses. There are in the city 290 schools and departments, including elementary, secondary, special and trade schools, and 269 of these reported cases of scarlet fever during the year, 2110 cases being notified. Scarlet fever followed on the heels of a widespread epidemic of measles. In one school—Blenheim-street—a case of measles was reported in the infant school on May 1st. The first crop of cases occurred from May 8th until the 15th; the infected class was closed on May 29th, when the epidemic had run its course and the second crop was falling "in the hope that other cases already infected would develop the disease out of school." This hope was promptly realised; the epidemic became thoroughly out of hand and continued throughout the year, 120 schools and departments being closed. Dr. Algernon Weir is inclined to the view that want of sunlight and the low summer temperature were the predisposing causes. At routine inspections 25,673 children were seen. Of these 2884 were found suffering from malnutrition, 10,304 from defective vision, 5706 from nose and throat affections, 308 from defective speech, and 1689 children were under special observation for subnormal nutrition. 5678 children were referred for treatment. A new system has been adopted whereby treatment is paid for by parents according to their means, whereas formerly treatment at clinics was free. During the year 38,154 children received treatment, including 15,073 dental and 14,226 minor ailment cases.

The Services.

ROYAL ARMY MEDICAL CORPS.

Maj. J. E. Powell retires on ret. pay and is granted the rank of Lt.-Col.

MILITIA.

Capt. I. M. Pirrie relinquishes his commn. and retains the rank of Capt.

TERRITORIAL ARMY.

Capt. V. C. de Boinville relinquishes his commn. and retains the rank of Capt.

Capt. J. Eason, having attained the age limit, is retired and is granted the rank of Maj.

Capt. H. Platt relinquishes his commn. and retains the rank of Capt.

DEATHS IN THE SERVICES.

Lt.-Col. James Currie Robertson, I.M.S., C.M.G., C.I.E., C.B.E., who died from heart failure following pneumonia on May 13th, graduated in medicine and surgery at Glasgow University in 1894, and two years later received his first commission in the Indian Medical Service. In 1897 he was placed on plague duty, and in 1901, having already reached the rank of Captain, he was appointed Deputy Sanitary Commissioner to the Government of India. He was later deputed to South Africa for the purpose of organising concentration camps, and became Sanitary Commissioner in India in 1912, five years before reaching the rank of Major. For service in the Soudan he was decorated with medals in 1896, and for service in South Africa the medal with clasp in 1902.

UNIVERSITY OF ABERDEEN: STUDENTS' HOSPITAL GALA WEEK.—As the result of the Gala Week (April 23rd to 28th) held by students, the local hospitals will benefit to the extent of £4753. This was the fourth gala week organised by the students. In 1920 the aggregate sum received without deducting expenses was £1560, in 1921 £2230, in 1922 £4266 and this year £4971. From the official financial statement issued by the Gala Week Committee of the S.R.C. some idea of the various forms of appeal and the success met with may be gathered.

Jazz band performances, £523; collections in outlying districts, £887; sports day, £107; rectorial dance, £201; football match, £245; house to house collection, £501; dramatic performance, £304; beach day, £216; street day, including torchlight, £1453.

The money was allocated as follows: Royal Infirmary, £3000; Sick Children's Hospital, £1000; Maternity Hospital, £500; Morningfield Hospital, £100; Eye Institution, £100; Aberdeen District Nursing Association, £53.

PSYCHO-PATHOLOGY IN THE CURRICULUM.

To the Editor of THE LANCET.

SIR,—I am interested in your excellent leading article in THE LANCET of last week and in the "suggested schedule of training for the general practitioner" proposed by Sir George Newman. This schedule corresponds very closely to the teaching that has actually been provided for the last three years in the Psychiatric Department of Edinburgh University, which is as follows:—

1. There is a course of 20 lectures on "Psychology for Medical Students," given by the distinguished reader in psychology, Dr. James Drever. This course is optional but it is well attended.

2. Eight tutorial lectures are delivered on psycho-pathology, psycho-therapy, psycho-analysis, and mental tests by the two university assistants in psychiatry. Specialists such as Dr. W. H. Bryce, of Kenlaw House, and Dr. Murray Lyon (hypnotism) have also assisted.

3. Twenty systematic lectures and clinics on mental diseases are given by the professor of psychiatry. Dr. Clarkson, of the National Institution for the Training of Imbeciles (which the students visit), lectures on mental defect.

4. The Royal Infirmary, Edinburgh, has wards containing 24 beds for early and mild cases of mental disorder, and Dr. J. D. Comrie, the physician in charge, gives weekly clinics. These are supplementary to the courses I have mentioned.

It will be noticed on comparing this teaching with Sir George Newman's suggested schedule that it exceeds his proposals very considerably, but nevertheless no difficulty is experienced in getting the students to attend as the subjects are very attractive to them after their prolonged studies in things material. In particular the time devoted to "Psychology for Medical Students" is from two to four times longer—20 lectures are given as compared with the 5 to 10 recommended by Sir George Newman. The Medico-Psychological Association (Section of Psychology and Neurology) have both petitioned all the licensing bodies and the General Medical Council to introduce compulsory attendance on psychology into the medical curriculum. I am chairman of a committee of the British Association (Section of Psychology), also appointed to consider this question and to report. In so wide and important a subject I think 20 lectures is a minimum.

I am, Sir, yours faithfully,

GEORGE M. ROBERTSON.

University of Edinburgh, May 21st, 1923.

THE ANATOMY OF THE PITUITARY REGION.

To the Editor of THE LANCET.

SIR,—From your annotation on the Bowman lecture (THE LANCET, May 5th, p. 912) it seems that Dr. George de Schweinitz, after paying a tribute to the memory of Sir William Bowman, detailed the results of his researches in conjunction with Dr. J. Parsons Schaeffer, professor of anatomy in the Jefferson Medical College, Philadelphia, into the anatomy of the pituitary region. "In 125 bodies examined," said Dr. Schweinitz, "it was found that the optic chiasma was in direct relation to the chiasmatic sulcus in only five (or 4 per cent.), although this was the position universally assigned to it in anatomical text-books." So far as I know, it may be true, even at the present day, that all anatomical text-books do make the statement ascribed to them, but I think it right to point out that the idea expressed by the two workers mentioned above is not new.

In the Proceedings of the Anatomical Society for May, 1894, Mr. T. W. P. Lawrence wrote: "In some recently observed specimens the commonly accepted

position of the commissure upon the optic groove was departed from; and although the number of cases examined was too small to justify the statement that the commissure never lies upon the optic groove he believed that such will be found to be the case." I myself had noted but not published the fact so far back as 1891, but in a communication to the *Journal of Anatomy and Physiology*, vol. xxx., entitled "Origin and Intra-cranial Course of the Ophthalmic Artery," I took the opportunity of drawing attention to the point in question and of confirming Mr. Lawrence's published observations. For many years I have abandoned in my lectures the use of the term sulcus chiasmaticus or optic groove and called that groove the olivary groove, which is merely a topographical name, and in the same lectures I have emphasised the fact that the groove is the result of the meeting of the anterior root of each orbito-sphenoid during the growth of the skull. The under free edge of each is sufficiently thick to produce a bar-like structure, the jugum sphenoidale, on the olivary eminence behind which there is a sort of groove which has been assumed to lodge the chiasma.

I am, Sir, yours faithfully,

EDWARD FAWCETT,

Professor of Anatomy, University of Bristol.
May 16th, 1923.

SERUM DOSAGE IN DIPHTHERIA.

To the Editor of THE LANCET.

SIR,—I am extremely sorry if I have in any way misquoted Dr. Frederic Thomson. I understood that his intervention in this discussion was primarily intended to support the dose recommended by the Ministry of Health for doubtful and suspicious cases, a dose which I had ventured to criticise as unnecessarily large for the purpose. I should have doubtless been more accurate had I used the words "as advised by the Ministry" instead of "as advised by Dr. Thomson," but I considered that Dr. Thomson was, so to speak, acting as champion of the Ministry's memorandum. All I meant to imply was that, where particularly severe forms of diphtheria are concerned, the dose "advised by the Ministry" was as little likely to be effective as the dose advised by myself, that both in all probability were directed merely against the average case and not specially virulent types. As regards the question of safety and efficiency I certainly felt that the Ministry's dose would not be harmful to the patient, and it must be remembered that some practitioners still seem to believe there may be risk in giving a large dose, and that it would be effective in securing, what I take it was the Ministry's object, a notable reduction in diphtheria mortality. I never intended to suggest that it would save every case. Dr. B. A. Peters has already assured us, and Dr. Thomson in his last letter agrees, that doses of 10,000 or 15,000 units, even if given on the first day, do not hold up cases of the type now prevalent in Bristol, so it is quite clear that 8000 units would be as useless as 3000 units, if given as a precautionary dose, while waiting for the result of the swab. It seems to me that those who suggest that the medical officer of health should advise practitioners when a severe type is prevalent and recommend a larger dose for the time being are quite right, and that it is not reasonable that the whole country should give unnecessarily large doses because, for instance, a severe type may be prevalent in the East-End of London.

I have not, to the best of my recollection, had a case of this type admitted to hospital on the first day; indeed, from the very nature of it it seems improbable that such an early diagnosis is likely except in a hospital official. I have not, therefore, had the opportunity of trying 60,000 units on the first day. Quite possibly, as it is impossible to compare cases, the types may be different, but in my experience 50,000 or 60,000 units given later seem to have very little effect.—I am, Sir, yours faithfully,

CLAUDE B. KER, M.D.

City Hospital, Edinburgh, May 12th, 1923.

TUBERCULOSIS OF THE SACRO-ILIAC JOINT.

To the Editor of THE LANCET.

SIR,—Through the kindness of a friend of mine I have now received copies of the actual tables in Dr. Rollier's "Heliotherapy," which were quoted by your correspondent Mr. P. B. Roth in his letter of May 5th, under this title, and which, he says, "for the sake of brevity I have combined in one table." If these tables which follow be compared with Mr. Roth's it will be seen that in his desire to be brief he has misquoted the headings and thus vitiated the evidence of the figures.

1903-1913.

Tuberculosis of the pelvic bones (and sacro-iliac disease).	Total	Healed.	Improved.	Stationary.	Died.
Without abscess ..	6	6	—	—	—
With abscess ..	10	10	—	—	—
With sinuses ..	21	9	1	6	5a
Total ..	37	25	1	6	5

H. C. W. NUTTALL.
Liverpool, May 19th, 1923.

THE MANAGEMENT OF PERITONITIS.

To the Editor of THE LANCET.

SIR,—In your leading article in THE LANCET of May 19th, referring to the Hunterian oration by Mr. H. W. Carson, it is stated that "irrigation of the cavity when the inflammatory process is diffuse is given up by nearly all surgeons. It is impossible to remove the infective material by this means; on the contrary, irrigation forces this material into unattacked regions, prolongs the operation, and damages the peritoneal membrane." I agree that irrigation of the abdomen in the presence of diffuse infection is a wrong procedure, and has very properly been given up by nearly every surgeon at the present day. The chances of the patient's recovery in such cases are greatly diminished by free irrigation. The modern procedure which is generally adopted of mopping out quickly the excess of fluid from the pouch of Douglas, introducing a large drainage-tube to the bottom of the pouch, keeping the patient in the Fowler position, supplying fluid either per rectum or, in more desperate cases, subcutaneously, getting the bowels to act by aperients as soon as possible, and washing out the stomach if necessary is attended by most excellent results. When, as was generally done 15 or 20 years ago, the abdomen was freely flushed or irrigated with saline few cases recovered. The reason for this is, I think, quite obvious. It was impossible, as you say in your article, thoroughly to remove all infection, but I do not agree that conveying infection to other parts of the abdomen (when, as is frequently the case, the whole abdominal cavity is infected) can do much harm, especially if the Fowler position is adopted afterwards; neither is it reasonable to suppose that any damage to the peritoneum would result from replacing stinking pus by normal saline. The length of time occupied by the process is a more serious objection. But the real objection is this.

During the development of a spreading general peritonitis, following, for example, the perforation of an appendix or a gastric or duodenal ulcer, there is an acute inflammatory condition of the serous membrane set up by the irritation of the highly toxic material in the abdominal cavity; this is accompanied by a free exudation of serum and migration of leucocytes into the cavity and the development of pus, all the flow is from the vessels into the abdominal cavity, and comparatively little of the toxic material is absorbed into the blood. If this were not so cases of general peritonitis would be far more rapidly fatal. But when the abdomen, containing a considerable quantity of septic pus, is freely irrigated with a fluid such as normal saline, a certain quantity of fluid is always left behind; this fluid, which is highly toxic, is rapidly absorbed into the circulation. It is well known that large quantities of normal saline, when introduced into the abdominal cavity, are very rapidly absorbed; the current is reversed; instead of being from the blood stream into the peritoneal cavity, it is from the cavity into the blood stream, and the patient dies of toxæmia.

This I believe to be the true reason why lavage of the abdomen in cases of general infection is such a useless and dangerous procedure, and why it should be emphatically condemned.

I am, Sir, yours faithfully,

HERBERT H. BROWN, O.B.E., M.D., F.R.C.S.

Ipswich, May 18th, 1923.

PROPHYLACTIC URETHRITIS.

To the Editor of THE LANCET.

SIR,—I was much interested in the annotation on prophylactic urethritis in your issue of Jan. 27th. In 1919 I was running a hospital in Scutari (Shkodra), Northern Albania, and an N.C.O. attended for acute urethritis. Repeated microscopic examinations failed to detect anything but pus cells. Afterwards I found that he had been using the calomel cream thrice daily since his indiscretion ten days before. Perhaps cases described by Drs. Bonnier and Rivoalen were also due to excessive use of the preventive. That the army issue is a preventive, if properly used, I have no doubt. I remember once in Egypt, on the first anniversary of the armistice, when the local disinfectant offices were for some reason closed, I found a very harassed orderly corporal in the hospital tent who said that during the night he had treated 60 men of the battalion. Not one of them developed venereal disease, though all had been exposed to infection. The only failure I had was a man who used the preventive six weeks after the event!

I am, Sir, yours faithfully,

L. FRASER, D.M.O.
(Late Captain, R.A.M.C.)

Famagusta, Cyprus, April 28th, 1923.

THE ORAL ADMINISTRATION OF PANCREATIC EXTRACT.

To the Editor of THE LANCET.

SIR,—A statement authorised by the Medical Research Council that preparations of the pancreas recommended for administration by the mouth have not the action of insulin, is rather hard to accept as final. It is true that there are many extracts of the gland for oral administration on the market which are without value, but have any of these been proved to act upon glucose in vitro? I am, however, glad to be able to report a substantial alteration in the urinary analysis of a patient—a girl of 9 years—who has had diabetes for five years and who has been under modified "Allen" treatment for over three years; this alteration I can only ascribe to the taking of the gland by the mouth. The extract was

supplied to me by Dr. R. L. Mackenzie Wallis, whose article upon its preparation appeared in THE LANCET on April 14th. For two and a half years the reappearance of sugar, from any cause, in the urine of this patient was invariably accompanied by the presence of diacetic acid. As a result of four weeks' treatment with Dr. Wallis's preparation this hitherto constant association has been abolished, and the diacetic acid is to-day only brought back by a considerable addition of fat to the diet. Otherwise, the child may pass sugar in the urine but no diacetic acid.

From a practical point of view this change is of the utmost importance in general practice, for whereas 14 months ago the onset simultaneously of glycosuria and acetonuria was so sudden that a semi-comatose condition was established by a dietetic error within 48 hours of the urine having been sugar-free; to-day the reappearance of the sugar—e.g., from an attempt to raise the carbohydrate of the diet—occurs well before that of the diacetic acid, resulting in a considerable margin of safety at any moment as regards life.

I consider it possible that, were larger quantities of this extract available, the metabolism of the carbohydrates would improve as that of the fats has done.

I am, Sir, yours faithfully,

Broadstairs, May 17th, 1923. MARTIN O. RAVEN.

THE CAUSE OF DEATH IN ANGINA PECTORIS.

To the Editor of THE LANCET.

SIR,—Every word that falls from the lips of Sir Clifford Allbutt—the greatest living authority on angina pectoris—commands my deepest respect. Points in my own experience at variance with his are few. In his lecture on angina pectoris published in THE LANCET of May 5th Sir Clifford Allbutt lays down three postulates, with which, in the main, my experience is in accord. I am unable, however, to accept the inference suggested in the first postulate—namely, that all true cases of angina are determined by organic disease. On the contrary, I think that evidence in abundance can be put forward showing that cases of a true but functional type are very numerous.

Symptoms of functional and organic disease such as those appearing in the angina pectoris are post-reflex phenomena and represent senses and functions disturbed through morbid conditions prevalent at reflex stations. On the other hand, pre-reflex impressions are silent. They present no signs and they pass unnoticed. Hence they have no proper name in the vulgar tongue of this or any other country. It matters little whether persistent pressure on splanchnic nerves be exerted from inside or from outside the aorta, whether it come from an aneurysm or from an œsophagus distended by gas—in both instances alike, through it, the central neurosis is generated and in both events the anginous syndrome appears. When pressure impinges on vagus nerves inhibitory signs follow and sudden death is not an infrequent incident. Whether the cause be functional, as in the case of distended œsophagus, or it be organic as in aneurysm, I think the resulting syndrome merits classification under the name of true angina pectoris, whereas Sir Clifford Allbutt holds the contrary opinion. Moreover, while in agreement with the view that death in anginous disease ordinarily results from vagus inhibition, I do not think that vagus inhibition is due to pain. Never, in my own practice, has death ended a paroxysm of severe pain. In the few fatal cases of anginous disease in which opportunities of obtaining precise information were at my command, death had come during intervals between seizures.

In two cases patients died while sleeping. In neither case had a change in pose immediately preceded death. In neither had the nurse in attendance been warned by cry or groan of the approach of death. In another instance death occurred in an anginous subject who several hours before death had been alarmed by the explosion of a bomb. He

was seated in my hall and my maid informed me that his gait was stumbling when he entered. He neither spoke nor uttered a sound, nor were his features expressive of pain. I raised his hand with the intention of feeling his pulse when suddenly he sank in the chair and died. Before the day of his death I had seen him on several occasions, after seizures, described by him as painful. In a fourth case the patient died after hastening home during a shower of rain. His wife left him seated in a chair before the fire. When she returned to the room a few minutes later, he was still seated and in the same pose as before, but dead. A lady who had suffered from attacks during the last ten years of her life died suddenly during a painless seizure following a meal of indigestible food. A solicitor who previously had suffered from several seizures, hastened his midday meal to attend a meeting, when rising to speak he suddenly fell back into his chair and died. Mr. G. left his house after eating a heavy midday meal. He had suffered from many seizures during the previous year. When distant from his own door about 200 yards he fell down and was picked up dead. No lesion accounting for death was found at the necropsy. All his organs were healthy. The aorta was free from disease.¹ Another patient died while running across a road to escape accident from traffic.

Pain belongs to the category of protective reflex phenomena. Rather than promoting, it opposes inhibitory action. It hardens the pulse and reduces the length of the diastolic period, and through the latter action it increases the beat rate and strengthens the beat. While engaged in taking polygraphic tracings I have had, on several occasions, the opportunity of noticing the mode of initiation of attacks and changes occurring in the curve. On the advent of severe pain, a pulse previously slow quickens its pace, through curtailment of the diastolic period and palpation at the wrist reveals the fact that contemporaneously with a quicker pace the radial artery becomes harder and less compressible. These changes in pulse-frequency and in conditions of the arterial wall indicate reduction of vagus influence and increase of splanchnic. In one case instantly after the onset of pain frequency of the pulse had increased from 46 beats a minute to 138.

Arrhythmia subsides on the advent of pain. In the series of cases already mentioned, one showed extra-systolic deflexion. After commencement of pain the irregularity no longer appeared. Cases obviously spurious are excluded from my category—namely, those of persons who die in great agony from accidental causes, such, for instance, as death from rupture of saccular and dissecting aneurysms or from hæmorrhage into the mediastinum from carcinomatous or from other new growths.

I am, Sir, yours faithfully,

H. WALTER VERDON.

Wimpole-street, W., May 12th, 1923.

THE TREATMENT OF STAMMERING.

To the Editor of THE LANCET.

SIR,—It is gratifying to know that the X ray investigation first carried out by my mother, the late Mrs. Emil Behnke, and by myself, as far back as 20 years ago, is corroborated at St. Thomas's Hospital. This further testimony to the fact, which we have always maintained, that stammering in its *physical* aspect is due to diaphragmatic spasm is welcome, because only through such knowledge, and by the correlating of cause and effect, will satisfactory results of treatment be obtained.

Mrs. M. H. Wigglesworth² says she does not think that the quickest way of giving a stammerer self-expression has yet been discovered, but when it is realised that diaphragmatic spasm—which can be clearly observed by means of the X rays—is usually due to nervous apprehension, and that the stammer has in the majority of cases been caused in the first place by nervous shock of some kind, it will be understood that speedy cure, though occasionally achieved, must not be expected. Long and patient work is usually needed to eradicate the psychic causes; muscle re-education will be necessary if the stammer be of long standing.

¹ THE LANCET, May 12th, p. 978.

² THE LANCET, April 3rd, 1915.

and the difficulties are generally increased by the fact that many stammerers are deficient in tone perception and sense of rhythm. Probably the extremely low rate of 5 per cent. of cure which has been mentioned is accounted for by the difficulty of getting patients to attend the clinic for a sufficient time and to carry out the necessary practice. The higher rate of 50 per cent. of cure obtained in the L.C.C. classes is doubtless due to the greater control obtained over such pupils, and naturally in private practice the results will be better still—my own being about 80 per cent.

I am, Sir, yours faithfully.

KATE EMIL BEHNKE.

39, Earl's Court-square, S.W., May 17th, 1923.

Medical News.

UNIVERSITY OF LONDON.—At a meeting of the Senate held on May 16th, Dr. James Calvert was appointed to represent the University at the Ninth Annual Conference on the Prevention of Tuberculosis to be held at Birmingham on July 12th and 13th next; and Dr. John Fawcett was reappointed to represent the University on the Council of the Lister Institute of Preventive Medicine for the period 1923-33.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH, ROYAL COLLEGE OF SURGEONS OF EDINBURGH, AND ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—The following candidates, having passed the requisite examinations, have been admitted Diplomates in Public Health:—

John M. Blair, John A. C. Guy, George L. Johnston, Elizabeth C. Loudon, Peter MacCallum, Patrick J. McDiarmid, Douglas O. Macdonald, Kenneth D. Murchison, George F. B. Page, Andrew G. Petrie, Ruth J. D. Ritchie, Marion Smellie, George D. Steven, Marjorie Thomson, Ruby Thomson, Peter Viera, William H. Wallace, and Enid Anne Williams. The following candidates passed Part I.: Marion B. Armstrong, Catherine McLean Buchanan, Helen Campbell, William Campbell, Alisdair C. Dewar, Katrine Dunn, Margaret A. Galbraith, James S. M. Gray, Katharine J. Guthrie, James L. Halliday, Mary N. Hendry, Catherine Hill, Alexander R. Lester, William McKie, Peggy L. Mitchell, John T. Moffat, George W. Murray, David T. Richardson, Robert G. Shaw, Charles M. Smith, Elizabeth N. Thomson, Sarah B. H. Walker, and Robert H. Williamson.

The following candidates passed Part II.: George Buchanan and Joseph G. Tait.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.—At a meeting of the College held on May 16th the following candidates, having passed the requisite examinations, were admitted Fellows:—

Balvant Vasdeo Abhyankar, Frederick G. Beatty, Isidore J. Block, Stuart Bolton, Hugh F. Briggs, Charles C. Bryan, Alistair F. Cowan, Upendra Nath Das, Gerald C. Dixon, Norman M. Dott, John Dunlop, Rupert S. A. Graham, James B. Hance, Frank C. Hutchison, James F. Jefferies, Cecil E. McQuade, Arthur G. Ord, Douglas S. Pracy, Alfred H. Proctor, Johannes Z. H. Rousseau, William O. Stevenson, and Andrew Watson.

The Bathgate Memorial Prize, consisting of bronze medal and set of books, was after a competitive examination in materia medica, awarded to Mr. Douglas Bannerman Craig. The Ivison Macadam Memorial Prize in Chemistry, consisting of bronze medal and set of books, was awarded, after competitive examination, to Mr. Henry William Bambridge.

The following candidates having passed the requisite examinations received the Higher Dental Diploma:—Nicholas Johannes Laubscher and Frederick H. Rowat.

INTERNATIONAL CONGRESS OF THALASSO-THERAPY. The International Congress of Thalasso-therapy, which has just been held at Venice, has given rise to important communications. The main question on the agenda was the examination, from every aspect, of the factors determining biological action in diverse maritime resorts. Mr. Bagot (Roscoff) communicated results of the study of the different characteristics of the coastal resorts in modern Brittany, where the temperature is moderate, with no great cold in winter and no great heat in summer. He pointed out that the climate of these resorts is admirably adapted to sufferers from chronic diseases with general debility, while it is contra-indicated for sufferers from erethic and febrile conditions, particularly for patients with pulmonary tuberculosis. Mr. de Francesco reported on the methods followed at the Lido (Italy) in applying helio-therapeutics. Mr. Comisso (Triest) and Mr. Léo (Paris) discussed various methods of thalasso- and helio-therapy. The next Congress will meet in 1925 at Arcachon (France), when the thalasso-therapy of rickets and the analysis of its action will be discussed.

SCHOOL OF HYGIENE.—The Minister of Health, with the concurrence of the trustees of the Rockefeller Foundation, has appointed a transitional executive committee in connexion with the proposed School of Hygiene. The functions of the committee will be to appoint a director, to arrange for amalgamation or coördination between the school and other institutions working in similar or closely related spheres, to prepare plans for the new school, and to begin building, unless in the meantime it has been possible to set up the permanent governing body. The members of the committee are: Mr. Neville Chamberlain (chairman), Lord Burnham, Sir Arthur Clarke, Sir Walter Fletcher, F.R.S., Lieut.-Col. F. E. Fremantle, Sir Harry Goschen, Sir George Newman, Sir Cooper Perry, and Sir Arthur Robinson, with Mr. L. G. Brock, of the Ministry of Health, as secretary.

HARVEIAN SOCIETY OF LONDON.—The annual dinner of this society will be held at the Connaught Rooms, Great Queen-street, W.C. 2, on June 14th, at 7.30 P.M.

ROYAL INSTITUTION OF GREAT BRITAIN.—On May 31st Sir William Bayliss, F.R.S., will deliver his first lecture on the Nature of Enzyme Action. The Friday evening discourse on June 1st will be delivered at 9 P.M. by Prof. H. A. Lorentz, of Haarlem University, on the Radiation of Light.

RONTGEN SOCIETY.—The annual general meeting will be held on June 5th, at 8.15 P.M., in the Institution of Electrical Engineers, Savoy-place, Victoria Embankment, London, W.C. A paper on the Effects of X Rays of Different Wave-Lengths on Animal Tissue will be read by Prof. Sidney Russ, D.Sc., and one on the Establishment of a Definite Relationship between Exposure and Density in an X Ray Plate by Mr. T. Thorne Baker, F.I.C.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—The annual dinner will be held at the Café Monico, under the presidency of Dr. A. G. Wells, at 7.45 P.M., on June 19th. Tickets may be obtained from Surg.-Capt. Guy Chambers, 101, Goldhawk-road, London, W. 12. On June 22nd, at 8.15 P.M., at the Kensington Town Hall, the Cavendish Lecture, entitled Speech and Cerebral Localisation, will be delivered by Dr. Henry Head, and will be followed by a conversazione, with a display by all the principal medical supply companies.

SEVENTEENTH FRENCH CONGRESS OF MEDICINE.—This Congress will take place at Bordeaux from Sept. 27th to 29th, under the presidency of Dr. X. Arnoz. The following subjects will be dealt with: (1) Late Results of Paludism (introduced by Prof. Le Dantec and Drs. Hesnard, Marcel Léger, and Broden); (2) Pathological Relationship of the Sympathetic Nervous System and the Endocrine Glands (introduced by Profs. Pachon and Perrin); (3) Treatment of Meningococcal Infections (introduced by Drs. Dopter and Boidin). The secretary to the Congress is Dr. R. Cruchet, 12, Rue Ferrère, Bordeaux.

FELLOWSHIP OF MEDICINE.—The Fellowship of Medicine have been proceeding successfully with the suggested scheme of post-graduate teaching outlined in THE LANCET, and already considerable progress has been made. The general non-undergraduate hospitals have taken up heartily the idea of the suggested grouping system for the holding of short "refresher" courses, and in some cases spontaneous offers have been received from special hospitals wishing to be included in these groups. Dates have been agreed upon for these courses up to a year hence, so that there will be a course lasting for two weeks during each month of the year. The response received from the special hospitals has been so good that it has been no light task to arrange dates so that no two special courses in the same subjects shall take place simultaneously. The complete programme for the year will be published shortly.

The courses arranged for next month include a "refresher" course at the Prince of Wales's General Hospital and affiliated hospitals from June 11th to 23rd, and a course on gastrointestinal diseases of children at the Children's Clinic, Western General Dispensary, from June 11th to July 5th. For those desiring work in the special departments of Ophthalmology, Neurology, and Dermatology, should a sufficient number of entries be received, courses beginning on June 11th and continuing for about four weeks will be given at the Royal London Ophthalmic Hospital, West End Hospital for Nervous Diseases (provisionally), and St. John's Hospital for Diseases of the Skin, respectively. Copies of the syllabus can be obtained from the Secretary to the Fellowship of Medicine, 1, Wimpole-street, London, W., to whom application for particulars regarding these and future courses should be made.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

WHITSUNTIDE ADJOURNMENT: THE CHANGE IN THE PREMIERSHIP.

PARLIAMENT adjourned for the Whitsuntide recess on Thursday, May 17th. Among the Bills to which the Royal Assent was given by Royal Commission was the Dangerous Drugs and Poisons (Amendment) Bill.

On Sunday, May 20th, Mr. Bonar Law, the Prime Minister, acting on the opinion of his medical advisers, tendered his resignation to the King, and it will be remembered that this possibility was recognised by himself at the time of his acceptance of office. Mr. Bonar Law during his brief tenure of the premiership showed qualities which have recommended him highly to all parties and sections, and his retirement is the subject of wide regret, while its cause has brought no less wide sympathy.

On Tuesday, May 22nd, it was officially announced that Mr. Stanley Baldwin, the Chancellor of the Exchequer, who had been Leader of the House of Commons in Mr. Bonar Law's absence, had been appointed Prime Minister.

HOUSE OF COMMONS.

WEDNESDAY, MAY 16TH.

Medical and Surgical Insurance Benefits.

Mr. RHYS DAVIES asked the Minister of Health what were the respective amounts set aside by Approved Societies under their schemes following the first valuation of Approved Societies for the provision of dental treatment, optical treatment, convalescent home treatment, medical and surgical appliances, and nursing, respectively.—Mr. NEVILLE CHAMBERLAIN replied: Out of the disposable surpluses of Approved Societies in England, following the first valuation, the aggregate amounts set aside for provision of the benefits in question during the five years covered by the schemes are as follows: Dental treatment, £495,000; optical treatment, £106,000; hospitals and convalescent homes, £979,000; medical and surgical appliances, £164,000; and nursing, £107,000. As regards the third item it is not possible to say what portion of the figure of £979,000 was allocated to convalescent home treatment, this benefit being included under the schemes with hospital treatment; but it may be mentioned that in addition the amount of £60,000 was set aside for the leasing and maintenance of convalescent homes of certain societies.

Medical Inspection of Employees.

Mr. GROVES asked the Minister of Labour whether he is aware that in some large firms the medical inspection of prospective employees was of such a character that ex-Service men were penalised; and whether he would make representations to the firms on the King's Roll that whenever an ex-Service disabled man was able efficiently to perform the required work his disability should not be a bar to employment.—Sir MONTAGUE BARLOW replied: If the hon. Member will furnish me with details of any case where difficulty has arisen, I shall be glad to look into the matter and see if any steps can be taken in the direction he has indicated.

Advertisements on Official Medical Forms.

Mr. THOMAS asked the Minister of Health under whose authority National Health Insurance Form Med. 40 B (revised) was being used for advertising Maypole for butter and tea; the amount gained by these advertisements; and the purpose to which the money was applied.—Major BOYDREPPEN replied: In view of the urgent need for exercising every possible economy in public expenditure, the Government has decided that official publications and forms which can be used as a medium for advertisement should be so used. The general arrangements for putting this decision into operation are in the hands of the Controller of His Majesty's Stationery Office, but before any advertisement is inserted on forms issued by or on behalf of any public department the Controller consults that department. The objections to the insertion of an advertisement on Form Med. 40 B were considered, but were not deemed to be so great as to justify a departure from the general rule that available space should now be used for advertisements. The insertion of an advertisement actually operated against the effective use of the form. With regard to the second part of the question the net income derived from advertisement is £135. This revenue is applied as an appropriation in aid of the Stationery Office vote, on which the cost of producing the forms is borne.

Criticisms of the Panel System.

Mr. JARRETT asked the Minister of Health whether his attention had been called to recent criticisms of the panel

system under the National Health Insurance Act; and whether he would institute an inquiry into the working of the Act.—Mr. HURD asked the Minister of Health if he would institute an independent inquiry into the working of the panel system under the National Health Insurance Acts, so as to ascertain how best to remedy the defects revealed in ten years' working of the system.—Mr. NEVILLE CHAMBERLAIN replied: I am aware of recent criticisms of the panel system, which in a service of this magnitude are, I fear, inevitable. The revision of the terms of service of insurance practitioners with a view to securing a more efficient medical service under the Insurance Acts has been fully examined in consultation with the Insurance Consultative Council and the Insurance Acts Committee of the British Medical Association, and I do not consider that any useful purpose would be served by such an inquiry as the hon. Members suggest.

Small-pox and Vaccination.

Mr. BECKER asked the Minister of Health if, seeing that the cases and suspected cases of small-pox notified for 1921 were 336 cases, for 1922 were 979 cases, and for the first three months of 1923 520 cases, he could state the causes of the great increase of small-pox this year; if the disease was on the increase or decrease during April; and had he information indicating that the objection of people to being vaccinated was one cause for the increase.—Mr. NEVILLE CHAMBERLAIN replied: I am advised that the recent increase of small-pox may be attributed to the widespread neglect of vaccination and revaccination, and to the fact that small-pox is a disease of seasonable prevalence, the maximum incidence usually occurring at the end of the first quarter of the year. The number of cases notified in April was 139, as compared with 215 in the previous month.

Opticians as Dentists.

Colonel Sir ARTHUR HOLBROOK asked the Minister of Health whether he would consider an amendment to the Dentists Act which would enable opticians who had hitherto practised also as dentists to be placed on the same footing as dentists with regard to registration.—Mr. NEVILLE CHAMBERLAIN replied: So far as I am aware the particular combination of occupations to which my hon. and gallant friend refers is not sufficiently common to justify amending legislation.

Treatment Allowances to Ex-Service Men.

Mr. SHINWELL asked the Minister of Pensions what allowances were paid to ex-Service men at present in military hospitals on treatment when travelling to and from their homes on leave; whether any reduction on the allowance had been authorised recently; and if the allowance was subject to variation.—Captain CRAIG replied: Men undergoing extended in-patient treatment, who are receiving ordinary treatment allowances, may be granted leave, with free return tickets at six monthly intervals, or with single journey tickets at three monthly intervals. The treatment allowances in issue, in lieu of pension, continue to be paid during authorised leave but no additional subsistence allowance is paid. There has been no recent change in leave arrangements.

Disability Appeals.

Mr. BROTHERTON asked the Minister of Pensions whether an ex-Service man was allowed to appeal either to the entitlement or to the assessment tribunal in a case where the medical officers of the Ministry expressed the opinion that there was no disability; and, if not, would he arrange that a man should have the right of appeal in all cases where his private medical attendant certified that he was suffering from a disability due to war service.—Captain CRAIG replied: My right hon. friend has recently had this class of case, which is of rare occurrence, under his consideration, and although it is open to doubt whether in strictness they come within the terms of Section 8 of the War Pensions (Administrative Provisions) Act, 1919, arrangements will, it is hoped, be made to allow appeals to the Pensions Appeal Tribunal where the Ministry medical boards find no disability.

THURSDAY, MAY 17TH.

Blind and Crippled Children.

Mr. FOOT asked the President of the Board of Education the number of blind and crippled children, respectively, throughout the country for whom no educational provision was being made.—Mr. E. WOOD replied: There are about 500 blind or partially blind children and about 1300 crippled children for whom provision is not made in recognised schools or educational institutions.

Children and Tuberculosis.

Mr. FOOT asked the President of the Board of Education if there were any statistics available showing the number of children throughout the country suffering from tuberculosis for whom no educational provision was being made.—Mr. E. WOOD replied: The relevant statistics of the Board divide children into two categories, those ascertained at

medical inspection to be suffering from pulmonary tuberculosis and those ascertained to be suffering from crippling due to tuberculosis. According to the latest returns furnished by local education authorities, the number of children in the first category is, approximately, 20,000, of whom about 2000 are in special schools, 11,000 are in public elementary schools, and 7000 are attending institutions not certified by the Board or are not at school. In the second category, there are 13,000 children, of whom 1700 are in special schools, 6500 are in public elementary schools, and 4800 are attending institutions not certified by the Board or are not at school. It will be understood that such of these children as are in attendance at public elementary schools are not suffering from tuberculosis in an infectious form. Provision is made in the Code for the exclusion from public elementary schools by the school medical officer of any child whose presence might involve the spread of disease.

Excess of Births Over Deaths.

Captain WEDGWOOD BENN asked the Minister of Health what had been the excess of births over deaths in each year from 1865 to 1921, inclusive; and what was the number of marriages in 1921.—Mr. NEVILLE CHAMBERLAIN replied: In England and Wales the number of marriages in 1921 was 320,852. The excess of births over deaths in the years mentioned in the question is shown in the attached table:—

Year.	Excess.	Year.	Excess.	Year.	Excess.	Year.	Excess.
1865	257,160	1880	353,019	1894	391,462	1908	419,927
1866	253,181	1881	391,707	1895	353,294	1909	396,469
1867	297,276	1882	372,360	1896	388,604	1910	413,715
1868	306,236	1883	367,725	1897	380,196	1911	353,328
1869	278,553	1884	375,922	1898	371,024	1912	385,798
1870	277,458	1885	371,520	1899	346,847	1913	376,915
1871	282,549	1886	366,484	1900	339,232	1914	362,354
1872	333,642	1887	355,573	1901	378,222	1915	252,361
1873	337,258	1888	368,897	1902	404,971	1916	277,303
1874	328,324	1889	367,591	1903	433,643	1917	169,424
1875	304,154	1890	307,689	1904	395,605	1918	50,800
1876	377,653	1891	326,232	1905	409,262	1919	188,235
1877	387,704	1892	338,273	1906	403,800	1920	491,652
1878	352,034	1893	344,614	1907	393,821	1921	390,185
1879	354,134						

Clinics for Physically Defective Children.

Mr. FOOT asked the President of the Board of Education the number of local education authorities who had established clinics for the treatment of physically defective children and the number of authorities who had not yet established such clinics.—Mr. E. WOOD replied: Out of the 318 local education authorities in England and Wales, 297 have established clinics for the medical treatment of school-children found to be suffering from physical defects.

Medical Boards and Final Awards.

Mr. RITSON asked the Minister of Pensions whether the instructions to medical boards held in cases for final awards provided that the doctors should estimate the man's physical condition at the end of two years and assess the degree of disablement on the then probable condition; whether these instructions applied in the cases of men suffering from tuberculosis; and, if so, in view of the nature of that disease, would he issue instructions that final awards should only be given to men suffering from tuberculosis when the degree of disablement was 100 per cent.—Major TRYON replied: There is no such instruction. The regulations require that a man who has been on the pension list four years or more shall be considered for final award; and medical boards are instructed to furnish an assessment for the purpose of such final award unless the man is likely to get materially better or worse within a period not exceeding two years. The Boards are advised that cases of tuberculosis will, generally speaking, be found unsuitable for final award, but that each case should be considered on its merits. As at present advised, I am not prepared to modify the instructions.

Pensioners and Valvular Disease of the Heart.

Mr. ROBERT RICHARDSON asked the Minister of Pensions how many final awards had been made in cases of men suffering from valvular disease of the heart; whether in any case the award was a final weekly allowance; whether he was aware that, in the opinion of cardiac specialists, the majority of cases of valvular disease of the heart were likely to become materially worse and that it was not possible to say what the pensioner's condition would be at the end of two years; and whether he would issue instructions that final awards should not be made in cases diagnosed as valvular disease of the heart unless the degree of disablement was certified to be 100 per cent.—Major TRYON replied: I regret that the form in which the records of my department are kept do not enable me to distinguish readily between valvular disease of the heart and other forms of heart disease. The instructions relating to making of final awards

recognise the probability that cases of valvular disease of the heart will deteriorate. Medical boards are, in fact, advised that cases of this nature will ordinarily be found unsuitable for final awards, but that each case should be considered on its merits.

Assessments by Re-Survey Boards.

Mr. MUIR asked the Minister of Pensions whether, seeing that in certain cases men were not informed of the decision of the medical board when they attended for re-survey, and that this applied particularly to men suffering from a disease aggravated by war service, what was the reason for withholding from these men information as to their degree of assessment.—Major TRYON replied: There is no instruction that men with aggravated disabilities are not to be told their assessments by re-survey boards. Where, however, a board finds it necessary to obtain a specialist's opinion, or where the case is one of difficulty, the position is explained to the man and he is informed later of the result of his examination. I may add that the final decision as to the rate of assessment always rests with a medical board which has examined the man.

Medical Diary.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.
MEETINGS OF SECTIONS.

Monday, May 28th.

ODONTOLOGY: at 8 P.M.
Annual General Meeting:
Election of Officers and Council for 1923-24.
Paper: Dr. Sim Wallace: Observations on the Progress of Preventive Dentistry.

Tuesday, May 29th.

MEDICINE: at 5.30 P.M.
Annual General Meeting:
Election of Officers and Council for 1923-24.

Cases:
Cases will be shown and discussed as follows:—
Dr. Parkes Weber: A case of Jaundice of 15 Years' Duration without Impairment of Health.
Dr. J. A. Ryle: A case of Splenomegalic Polycythæmia with Cerebral Hæmorrhage.

Thursday, May 31st.

UROLOGY: at 8.30 P.M.
Annual General Meeting:
Election of Officers and Council for 1923-24.

Paper:
Mr. Jocelyn Swan: Carcinoma occurring in Clinical Innocent Enlargement of the Prostate.

SOCIETY OF MEDICAL HYDROLOGY.
TUESDAY, May 29th.—(At the University of London, South Kensington.) Lectures and Demonstrations in Medical Hydrology. (To be continued on Wednesday, Thursday, Friday, and Saturday.)

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE POST-GRADUATE LECTURES, 1, Wimpole-street, W.

WEDNESDAY, May 30th.—5.30 P.M., Mr. Ernest Clark: Tips in Ophthalmology for the General Practitioner.

LONDON HOSPITAL MEDICAL COLLEGE, Mile End, E.

TUESDAY, May 29th.—5.15 P.M., Dr. Millais Culpin: Treatment in Psycho-neurosis.

WEDNESDAY.—4.15 P.M., Dr. W. M. Feldman: Female Physiology.

FRIDAY, June 1st.—4.15 P.M., Mr. Russell Howard: (Lecture on Surgery) The Testicle. 5.15 P.M., Dr. Mill Culpin: Treatment (2).

WEST LONDON POST-GRADUATE COLLEGE, W.

Monday, May 28th.—12 noon, Mr. Simmonds: Applied Anatomy. 2 P.M., Mr. Bishop Harman: Eye Department. 3 P.M., Mr. Simson: Diseases of Women.

TUESDAY.—10 A.M., Mr. Steadman: Dental Dept. 12 noon, Dr. Burrell: Chest Cases. 2.30 P.M., Mr. Tyr Gray: Surgical Wards.

WEDNESDAY.—10 A.M., Dr. Saunders: Medical Diseases of Children. 12.15 P.M., Dr. Burnford: Medical Pathology. 2 P.M., Mr. Gibb: Eye Dept.

THURSDAY.—10 A.M., Dr. Grainger Stewart: Neurology Dept. 2 P.M., Mr. Bishop Harman: Eye Dept. 2.15 P.M., Mr. MacDonald: Genito-Urinary Dept.

FRIDAY, June 1st.—10 A.M., Dr. Drummond Robins: Gynaecological Dept. 2 P.M., Mr. Banks-Davies: Diseases of Throat, Nose, and Ear.

SATURDAY.—9.30 A.M., Dr. Burnford: Bacterial Therapeutics. 10 A.M., Dr. Saunders: Medical Diseases of Children. 10 A.M., Mr. Banks-Davies: Operations, Nose, Throat, and Ear.

Daily, 10 A.M. to 6 P.M., Saturdays 10 A.M. to 1 P.M., patients, Out-patients, Operations, Special Department.

SOUTH-WEST LONDON POST-GRADUATE ASSOCIATION, St. James's Hospital, Ouseley-road, Balham, S.W.

THURSDAY, May 31st.—4.30 P.M., Dr. H. Crichton Miller: Toxins, Endocrines, and Emotions.

NORTH-EAST LONDON POST-GRADUATE COLLEGE,
 Prince of Wales's General Hospital, Tottenham, N.
 Demonstration of Clinical Cases at 3.30 P.M.
MONDAY, May 28th.—Dr. J. Browning Alexander: Medical.
TUESDAY.—Mr. J. Howell Evans: Surgical (3 P.M.).
WEDNESDAY.—Mr. Norman B. Fleming: Eye Cases.
THURSDAY.—Mr. H. W. Carson: Surgical.
FRIDAY, June 1st.—Dr. C. E. Sundell: Diseases of Children.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C. 1.

POST-GRADUATE COURSE: MAY-JUNE, 1923.

CLINICAL LECTURES AND DEMONSTRATIONS.

MONDAY, May 28th.—2 P.M., Out-patient Clinic: Dr. Hinds Howell. 3.30 P.M., Ophthalmic Herpes: Mr. Paton.
TUESDAY, May 29th.—2 P.M., Out-patient Clinic: Dr. Grainger Stewart. 3.30 P.M., Syphilitic Disease of Nervous System: Dr. Adie.
THURSDAY, May 31st.—2 P.M., Out-patient Clinic: Dr. Kinier Wilson. 3.30 P.M., Pituitary Disease: Dr. Gordon Holmes.
FRIDAY, June 1st.—2 P.M., Out-patient Clinic: Dr. Gordon Holmes. 3.30 P.M., Trauma in Relation to Nervous Disease: Dr. Collier.

COURSE OF LECTURES ON NEURO-PATHOLOGY.

MONDAY, May 28th.—12 noon, Paths of Infection on Central Nervous System: Dr. J. Godwin Greenfield.

A COURSE OF 12 LECTURES ON THE ANATOMY AND PHYSIOLOGY OF THE NERVOUS SYSTEM will be given at 12 noon on **TUESDAYS** and **FRIDAYS** if there are sufficient entries for it.

Mr. Armour and Mr. Sargent operate at the Hospital on Tuesday and Friday mornings at 9 A.M., or at such other times as may be announced.

The fee for the whole Course is £12 12s., including Anatomy and Physiology, but these Lectures may be taken separately for a fee of £4 4s. The fee for the Course without Anatomy and Physiology Lectures is £10 10s. Special arrangements as to fees will be made for those unable to take the whole Course. Fees should be paid to the Secretary of the Hospital at the office on entering for the Course.

C. M. HINDS HOWELL, Dean of Medical School.

MEDICAL OFFICERS OF SCHOOLS ASSOCIATION, 11, Chandos-street, Cavendish-square, W.

TUESDAY, May 29th.—5 P.M., Dr. Alice E. Sanderson Clow: The Effects of Physical Exercise on Menstruation.

INSTITUTE OF PATHOLOGY AND RESEARCH, St. Mary's Hospital, Paddington, W.

THURSDAY, May 31st.—4.30 P.M., Dr. Leonard Hill: New Ideas concerning the Biological Action of Light.

LONDON SCHOOL OF MEDICINE FOR WOMEN, 8, Hunter-street, W.C.

TUESDAY, May 29th.—5 P.M., Prof. A. L. McIlroy: Haemorrhage in Pregnancy.

ONDON LOCK HOSPITAL, 91, Dean-street, W. 1.

MONDAY, May 28th.—5 P.M., Mr. Charles Gibbs: Antenatal and Post-natal Treatment of Syphilis.

TUESDAY.—2.30 P.M., Mr. J. E. R. McDonagh: Microscopic Demonstration of Leucocytozoön Syphilis.

At 283, Harrow-road, W. 9.
WEDNESDAY.—3 P.M., Mr. Ernest Lane: Treatment of Gonorrhoea in Women.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.

THURSDAY, May 31st.—4 P.M., Mr. Higgins: The Acute Abdomen.

INFANTS HOSPITAL, Vincent-square, S.W. 1.

MONDAY, May 28th.—6 P.M., Dr. Eric Pritchard: Rickets.

TUESDAY.—8.45 P.M., Mr. M. S. Mayou: Prophylaxis and Treatment of Common Diseases of the Eye in Children.

THURSDAY.—6 P.M., Dr. Eric Pritchard: Weaning and Feeding up to 5 Years.

FRIDAY, June 1st.—8.45 P.M., Dr. H. MacCormac: Treatment of Eczema in Infants.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone-road, N.W.

THURSDAY, May 31st.—5 P.M., Mr. Aleck W. Bourne: Puerperal Sepsis.

ANCHESTER ROYAL INFIRMARY POST-GRADUATE LECTURES.

TUESDAY, May 29th.—4.15 P.M., Mr. W. R. Douglas: Chronic Appendicitis.

UNIVERSITY OF BRISTOL POST-GRADUATE DEMONSTRATIONS.

MONDAY, May 28th.—At Hereford, Dr. C. E. K. Herapath: Tachycardia.

THURSDAY.—At Bristol, Prof. Walker Hall: Normal and Acquired Resistance to Disease.

MACLEAN, N. A., M.B., Ch.B. Glasg., House Surgeon, Adden-brooke's Hospital, Cambridge.
 RADLEY, S. B., M.B. Lond., F.R.C.S. Eng., Honorary Surgeon to the Newark and District Hospital.
 Certifying Surgeons under the Factory and Workshop Acts:
 MORRIS, S. G., M.D., C.M. Edin. (Rhondda, Porth); COHEN, S. M., M.D., B.S. Lond. (Rhondda, Treorchy).

Vacancies.

Births, Marriages, and Deaths.

BIRTHS.

DAWSON.—On May 13th, at "Brooke," Torquay, the wife of Captain F. G. L. Dawson, R.A.M.C., of a daughter.
 GREENWAY.—On May 9th, at Plumstead High-street, the wife of Dr. Chas. M. Greenway, of a daughter.
 PATTERSON.—On May 14th, at Pirbright, Surrey, the wife of Captain A. F. L. Patterson, D.S.O., R.A.M.C., of a daughter.
 ROBERTS.—On May 16th, at the Parsonage, Kuala Lumpur, F.M.S., to Dorothy M. Roberts, M.B., Ch.B. (née Somerville), the wife of Rev. B. C. Roberts—a son.

MARRIAGES.

KEANE—CHAPMAN.—On May 16th, at Westminster Cathedral, by Rev. Father Keane, Rector of Campion House, Oxford, Major Gerald J. Keane, D.S.O., to Auriol Frances Kyrle Chapman.

DEATHS.

GARMAN.—On May 14th, at Oakeswell Hall, Wednesbury, Walter Chancellor Garman, M.D. Edin., J.P.
 ROBERTSON.—On May 15th, at Simla, India, of heart failure following pneumonia, Colonel James Currie Robertson, C.M.G., C.I.E., C.B.E., I.M.S.
 SWAINSON.—On May 16th, suddenly, James Middleton Graham Swainson, F.R.C.S., Elms-road, Clapham, and Welbeck-street, in his 51st year.
 WILLEY.—On May 16th, at Somersfield, Reigate, Surrey, Henry Willey, M.D., F.R.C.S., aged 84 years.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Appointments.

ERTIS, H., F.R.C.S. Eng., has been appointed Consulting Surgeon, Metropolitan Hospital, London.
 UNSCOMBE, C., B.Ch. Camb., M.R.C.S., L.R.C.P. Lond., D.P.H. Oxf., Resident Medical Officer to the Brighton Isolation Hospital and Sanatorium.
 BSON, J. M., M.D., D.P.H. Belfast, Medical Officer of Health and School Medical Officer for the Medical District of Radcliffe, Lancashire.

Notes, Comments, and Abstracts.

THE PATHOLOGICAL GALL-BLADDER.*

BY ARIAL W. GEORGE, M.D.,

ASSISTANT PROFESSOR OF ROENTGENOLOGY, TUFTS COLLEGE
MEDICAL SCHOOL, BOSTON.

AFTER referring to the pleasure with which he had accepted the invitation to come to England and discuss the subject of the pathological gall-bladder, and expressing the belief that the English-speaking peoples lead, and should continue to lead, in this specialty, Dr. George continued as follows:—

No one can approach the gall-bladder problem without being familiar with the work of Robert Knox. To my colleague Dr. Leonard and myself, this work of Knox was probably our greatest stimulus in our early work upon gall-bladder disease and gall-stones. Yet possibly we were a little discouraged in a careful analysis of his work, because of the fact that there was a large group of gall-stones not visible to the X ray, owing to their physical qualities. In the early days, when we attempted to carry out the study of the duodenum by the plate method introduced by Cole, of New York, we occasionally found shadows either distinctly due to gall-stones or very suggestive of gall-stones. We spent a great deal of effort, time, and study to determine in each and every case that came through our clinic whether stones existed or not. After having had considerably more success than we at first hoped for, we realised that many cases showed indefinite shadows only suggestive of gall-stones in shape, size, position, and a certain amount of increased density; the question therefore arose whether these shadows might be due to a collection of stones in the gall-bladder. Through a period of time when we met with discouragement from every angle, especially from our colleagues in the demonstration of these cases, in a good many cases, where we thought by the density of the shadow and by the shape that we were possibly dealing with gall-stones, we found at operation that the gall-bladder did not contain stones, the shadows being due either to thickening of the gall-bladder wall, inspissated bile, or very thick and dark bile. We became convinced after a series of these cases that we were actually making visible the gall-bladder itself. Thus we changed our opinion, or our method of reporting, and considered it as "the pathological gall-bladder."

Invisibility of Normal Gall-Bladder.

It then became perfectly obvious from previous experience in gastro-intestinal work, especially the study of the upper right quadrant, that we were not yet able to make visible the normal and healthy gall-bladder, and I believe that this statement holds to-day, although there may be an occasional exception to this rule—that is, there may be times when we do show the normal gall-bladder. Thus, when we made visible a shadow in the upper right quadrant consistent in size, shape, and position with what we understand to be the gall-bladder, we considered this to be a pathological gall-bladder with or without gall-stones. The effort of our colleagues and of most of the roentgenologists seemed to be aimed at proving that they could demonstrate the normal gall-bladder rather than trying to demonstrate the pathological gall-bladder. For a time we, in our clinic, stood alone in the study of the pathological gall-bladder; only within recent months has there been a general change of opinion, brought about largely by Kirkland, of Muncie, Indiana, who was associated with me on war service. On his return to civil practice Kirkland, being in a part of the country where gall-bladder disease and gall-stones are apparently common, made in a year or two a collection almost equalling ours in numbers, carrying out his work along the same lines. He was invited to the Mayo Clinic for two months to X ray the gall-bladder cases which were to be operated on, having been diagnosed as gall-bladder disease or stones from the clinical history. Though I have not his exact figures, it is reported that he made 92 per cent. correct diagnoses in a series of cases operated upon, well over 100 in number. This seems a startling but very satisfactory demonstration of individual ability to make this study exact and worth while.

Later, as we perfected the technique of the examination of the upper right quadrant, there came a time when we needed, in a large number of cases, other evidence to help substantiate the visible gall-bladder, so we began to enumerate and classify observations which we called "indirect evidence" or "secondary evidence." We prefer the latter term.

Pressure Deformity.

We found that the normal healthy gall-bladder did not

cause pressure so that it would outline itself upon the barium mass. We also found, however, that when we obtained this pressure deformity of a certain character it was almost conclusively due to the gall-bladder, and in almost every instance to disease of the gall-bladder—in other words, we were dealing with a pathological gall-bladder.

We classify this filling defect, or pressure deformity, in various ways. The effect of the gall-bladder is upon the first portion of the duodenum, in both the antero-posterior and lateral diameters. We may find in the gastro-intestinal examinations deformity of the first portion of the duodenum due to various causes, such as poor filling of the cap at the moment of exposure, malposition of the stomach for various reasons, either normal or abnormal, spasm at the pylorus, adhesions, and ulcer. I believe that most of us can recognise the characteristic changes of ulcer as easily as cancer of the stomach. There may be unusual deformities, sometimes hard to differentiate from ulcer, but we have our method of determining this with more or less certainty.

In deformity due to a gall-bladder we have a definite and tangible shadow, which we have termed a "half-shadow," due to the concave or rounded surface of the gall-bladder pressing against the similar surface of the duodenum. If the edge of the liver, which is a flat surface, presses against the duodenum, we lack this "half-shadow" as we have no concavity to produce this half-shadow. My own colleagues in America have not seemed to grasp the fundamentals of pressure deformity due to the gall-bladder; the interpretation or differentiation of pressure deformity due to a gall-bladder in contradistinction to that of a liver edge must be understood and recognised to make what I am going to say clear and easy to interpret.

Causation of Pressure.

Why should the gall-bladder cause this pressure? In the first place, we have pathological gall-bladders with no adhesions, and a great many with adhesions between the gall-bladder and the duodenum. The chances are that at some period of the examination or examinations there will be tension within a pathological gall-bladder greater than the tension within the duodenum when filled with barium. We conclude that when the stomach is in either the prone or lateral position it cannot, in view of the power exerted by gravity, peristalsis, and the weight of the barium mass, push to one side a gall-bladder in close approximation to the duodenum; we then have the feeling that tension is greater in the gall-bladder than in the duodenum. We admit that occasionally one finds a perfectly healthy gall-bladder which for a short period of time is under tension, but which empties itself sooner or later. On the other hand, a gall-bladder under tension with power to impose itself upon the first portion of the duodenum is potentially pathological in some degree.

Unfortunately, we must admit that under ordinary circumstances fluoroscopy does not help to determine these facts; the latter can only be obtained with the most careful plate or film method. Many cases show deformity not in the prone position, but only in the lateral position, so that all views must be taken. Many cases show pressure deformity of the gall-bladder upon the first portion of the duodenum in the lateral position, but they more frequently show the picking up of the second portion of the duodenum and its extension back toward the spine in the horizontal position. With gall-stones of the type invisible to X rays we occasionally see a serrated edge to the shadow produced by the gall-bladder against the duodenum.

I have no statistics as to the relative frequency of pressure deformity and pathological gall-bladder, but Dr. Leonard and I feel more convinced to-day than ever that this deformity is one of our strongest links in the chain of evidence toward the diagnosis of a pathological gall-bladder.

Involvement of Second Portion of the Duodenum.

The second important structure involved—although perhaps not so frequently as the first portion of the duodenum—is the second portion. Those who have carried out one method of procedure covering a large series of cases over a long period realise the position of the average normal stomach. In the prone position we find that the second portion of the duodenum extends downward parallel to the vertebrae, until it reaches its third portion, where it passes upwards and behind the stomach; the position of the second portion has a great significance in the diagnosis not only of gall-bladder disease but of other conditions.

Except in very stout or very poorly-nourished patients or in those with scoliosis or some skeletal defect which gives rise to change in the organs generally, the position of the second portion of the duodenum is constant as above outlined; a very common change due to gall-bladder disease is the picking up of the second portion of the duodenum outward toward the liver, and in quite a number of cases the size of the gall-bladder can be outlined by the position of the second portion of the duodenum. In the study of the pancreas, changes in the second portion form our most important diagnostic sign. In the lateral position instead of

* An abstract of the Mackenzie-Davidson Memorial Lecture, read at the First Annual Joint Meeting of the Roentgen Society and the Electro-Therapeutics Section of the Royal Society of Medicine on May 17th, 1923.

the second portion of the duodenum passing downward and parallel to the vertebræ, it often takes a backward curve, depending upon the size of the head of the pancreas. With a nodular pancreas this pressure deformity of the nodules will be seen on the barium-filled second portion of the duodenum so clearly that there is no great difficulty in the interpretation. Again, in the lateral position, a duodenum that passes backward toward the vertebræ and then forms an angle passing downward again to its normal position is most significant of gall-bladder disease. Burnham, of San Francisco, at a meeting of the American Roentgen Ray Society in September, 1922, definitely brought out this observation in a large series of cases.

In dealing with retroperitoneal tumours—for example, sarcoma—the duodenum will be found to be pushed in the opposite direction, and the tumour mass will be outlined upon the posterior portion of the duodenum; it can be detected by the new position which the second portion of the duodenum takes as compared with the normal.

It is, of course, unnecessary to say that the best results will be obtained by the plate or film method; with sufficient experience this observation can be detected fluoroscopically. In exception to general rules is the post-operative case; all the above observations may be valueless because of fixation, mental and otherwise. All cases that have had previous abdominal operation, especially of the upper right quadrant, are difficult to interpret, as normal relations are so definitely disturbed in some instances. We cannot urge too strongly a careful consideration of all these facts relative to gall-bladder disease. The second portion of the duodenum plays its most important part in the diagnosis of the gall-bladder region.

When the duodenum passes outward toward the liver and then proceeds downward to its normal position we must consider that this position of the duodenum is due definitely to fixation, and in only rare exceptions will this be found to be due to other than gall-bladder adhesions.

Pressure upon the Antrum.

Pressure of the gall-bladder upon the antrum of the stomach will occur as frequently as pressure deformity on the first portion of the duodenum; in a large number of cases it will be found on the first portion of the duodenum, extending to the antrum. In this observation we must look for the half-shadow effect. Another observation of value is the transposition of the jejunum from its normal position from the left to the upper right quadrant. This has frequently been of assistance to us in the determination of gall-bladder disease; but we appreciate from experience that tuberculous or other peritonitis earlier in life may be the cause. It is remarkable how easily the gall-bladder throws out adhesions and picks up adjacent structures.

Filling of the Ampulla of Vater.

A fourth observation of relatively common occurrence, but possibly not of quite such definite value, is the filling of the ampulla of Vater. We have found, in every instance in which we have had the cases operated upon, that if we could show the ampulla full of barium throughout a series of gastro-intestinal plates or films, this was significant of one of two conditions—gall-bladder disease or disease of the pancreas. We know, of course, that changes frequently occur in the pancreas secondary to chronic gall-bladder disease. At one time we kept a record of a series of these visible ampulla cases operated upon for gall-bladder disease and other conditions—the number of 27; in every instance they displayed disease either of the gall-bladder or of the pancreas, or both. All the other indications outlined are absent or cannot be demonstrated, and if we find only the filling of the ampulla of Vater, we feel that we have neglected for one reason or another to obtain the most satisfactory results from this method throughout the examination.

Change in Position of Proximal Portion of Transverse Colon.

Another observation that can be mentioned and which is of considerable importance is the change in position of the proximal portion of the transverse colon. In a way it forms a secondary hepatic flexure, or, as we have sometimes called it, a "pseudo-hepatic flexure." Very often in the absence of other signs this change of the transverse colon will be present and will constitute the only diagnostic sign pointing to the gall-bladder.

One other diagnostic factor brought forward by Carman, Burnham, and others, which we have felt was not entirely reliable, is so-called spasm which occurs in the antrum of the stomach. Possibly this should be observed with the fluoroscope rather than with plates or films; we do not attach any considerable significance to it, unless it appears in conjunction with other signs which make the diagnosis positive.

It can be readily seen that if the observations which I have enumerated are reliable we have considerable evidence to help towards the diagnosis of a pathological gall-bladder, aside from the visible gall-bladder. To me this makes the work still more satisfactory, because we are

not depending upon one diagnostic observation but upon numerous ones, any one of which may be of the utmost importance in a given case.

Negative Value of X Rays.

Many have asked the question, "What is the negative value of X rays?" We feel, perhaps more strongly than ever, that if we have evidence which makes for a positive diagnosis, then the absence of all of this evidence has some value towards the negative aspect of the study. We are sure that with a proper examination, in a given case of actual pathological processes of the gall-bladder can be in almost every instance recognised by changes manifested in the plate or film of the X ray examination. There are unquestionably degrees of pathological processes, such as mild cholecystitis, which do not change the quality of the bile to any extent or give rise to thickening of the bladder wall. I believe that even in these cases we can, with carefully taken films, bring out secondary evidence of diagnostic importance. Even with cholesterol stones, which are usually in numbers, if we have a large number we have mass, and if we have mass we have increased density. It may not always be possible to recognise individual stones, but with increased density, and taking into account the shape of the gall-bladder, we can be pretty sure that we are dealing with a chronic gall-bladder or with stones or both.

The question is then asked: "Why, when we have simply microscopical changes in the gall-bladder wall, can we detect these changes with X rays?" So far as our experience is concerned, and so far as we can find from the literature, the moment infection takes place in the gall-bladder there is change in the tissue of the gall-bladder, and immediately, or very soon, the bile becomes turbid, cloudy, considerably darker, and more tar-like. We found in a series of laboratory tests that this bile, as it darkens in colour from the normal, becomes denser in quality, with increase of opacity. We have had gall-bladders removed and with an immediate specific gravity test of the bile found it was double the normal. It is perfectly obvious that with this increase in density, or specific gravity, this condition is more easily recognisable with X rays.

Perseverance Necessary.

We have been asked many times by our colleagues, especially of the younger group, why we can show things so constantly when they are unable to do so with the same apparatus and with the same type of patient. Perhaps that question can be answered by stating that one big factor in gall-bladder work, aside from the necessary apparatus and facilities, is perseverance. The investigator should continue his work in an individual case until he has obtained, through a series of films, a most satisfactory film from every angle. This means that the patient must be absolutely at rest without breathing. The technique, the quality, and the exposure value must be exact for the individual case; for this there is no standard. The second big factor in this study seems to me to be a willingness to look for changes and to admit that the latter exist and can be found.

I think that, in view of our experience covering a number of years and a large series of cases, we have in the use of X rays a definite method of examination of the upper right quadrant. If we do not reach 100 per cent. of correct diagnoses, this does not relegate the method to a second place, for our percentages are as high as can be expected in any branch of medical science. Up to the present time no one method touches perfection, but our endeavour should be to make our practice in this specialty as near 100 per cent. as it is humanly possible.

SANITARY ADMINISTRATION IN THE PUNJAB.*

THE population of the Punjab, for which statistics are given in this report (that is, the civil population, less that of cantonments, of the Punjab States, and of the Biluch Trans-Frontier Tract) was, according to the census taken in March, 1921, 20,517,606; this total is less by 255,583 than the estimate obtained by the "natural increment" method—that is, the progressive total obtained by adding yearly the excess of births over deaths to the last census population. This deficit is to be attributed mainly to emigration. As compared with the 1911 census (19,337,146), there has been an increase of 6.10 per cent.; males number 11,204,834 and females 9,312,772, these figures showing increases of 5.63 and 6.69 per cent. respectively. Lieut.-Colonel W. H. C. Forster, I.M.S., director of public health for the province, who forwards this report for 1921 considers that the broad result is satisfactory; "owing to devastating epidemics population does not increase rapidly in the Punjab, the total increase in British territory since 1881 being only 3,746,114." An

* Lahore, 1922. Supt., Govt. Printing.

actual decrease has occurred in six districts, amounting in Gurgaon, Dera Ghazi Khan, and Jhelum to 6.47, 6.16, and 5.68 per cent. respectively. For the province as a whole there has been an increase of 5.92 per cent. among Mohammedans, who form more than half of the population; of 4.66 among Hindus, and of 90.82 among Indian Christians. The general birth-rate, 41.5 per 1000, was 1.4 less than that of the previous year, but 1.2 higher than the mean of the previous five years; the highest ratios were registered in Lyallpur (48.7), Gurdaspur (47.5), and Amritsar (47.3) districts; in the exceptional district of Simla, with the small population of 40,937, the ratio was only 20.0 per 1000; the next lowest ratio was that of 30.2 in Dera Ghazi Khan. The provincial rate was higher than that of any other, Central Provinces coming next with 37.90, and Madras showing the lowest ratio of 27.05 per 1000. For males the ratio (21.9) was 2.3 in excess of that for females, the same as in 1920.

The general death-rate of 30.1 per 1000 was 1.5 higher than that of 1920 (due to cholera and malaria), but 8.8 less than the five-year average; for males it was 29.7, and for females 30.6. In the neighbouring United Provinces the rate was 39.57, while in Burma it was only 21.45, and in Madras 20.18. In the districts of Kangra and Rawal Pindi the ratios were 56.5 and 47.7, due chiefly to cholera, plague, and fevers; in Montgomery and Sheikhupura only 16.5 and 18.5 respectively. The infantile mortality, 195.78 per 1000 births, exceeded that of 1920 (182.85), but was appreciably less than that of the previous quinquennium (215.55). Amongst Hindus the ratios were 209.39 and 195.38, amongst Mohammedans 206.08 and 177.63 for males and females respectively; while for Indian Christians they were 148.0 and 142.4, this comparatively low mortality being probably due to the attention devoted to them by the missions concerned. For the province generally the urban death-rate of 33.46 per 1000 exceeded that of the rural districts (29.76) under all the heads of mortality except "fevers," in which group, however, plague deaths may have been included in the country districts. Among these latter the total mortality varied from 16.57 in Montgomery (with a fever ratio of 13.61), and 18.92 in Sheikhupura (Lahore), also with a fever ratio of 13.61; to 46.36 (fevers 32.49) in Rawal Pindi, and 56.55 (fevers 33.03) in Kangra. In the towns the total mortality varied from 2.18 per 1000 in Mian Channu (Multan district), and 2.53 in Okara (Montgomery), to 76.65 in Kangra and 84.08 in Dasuyah (Hoshiarpur), cholera and fever being the chief fatal diseases, with the addition of dysentery (16.20) in the case of Kangra. It is impossible to attribute such excessive variations to climatic causes; there must be local conditions (presumably capable of improvement) that need attention. Relapsing fever prevailed in some districts, and is said to be of special interest in the province, although there is no heading in the tables showing its local incidence. In Palampur *tahsil* of Kangra district 34 villages were infected, the disease having been introduced from the contiguous Native State of Mandi, where it is said to be prevalent; in Simla town there were 41 cases, with 7 deaths. The disease is frequently overlooked, and Lieut.-Colonel C. A. Gill, chief malaria medical officer, considers that the total mortality from this cause was not less than 26,000. Enteric fever is not separately recorded for the province generally, but in Simla town there were 12 cases, four of which, however, were imported. Dysentery and diarrhoea accounted for 11,826 deaths (0.58 per 1000), as compared with 0.47 in 1920 and 0.58 in the quinquennium; at Rawal Pindi the mortality was 4.73, at Sheikhupura and Montgomery only 0.01.

The mortality from cholera was the highest on record since 1900: the deaths numbered 19,215, compared with 138 in the previous year, and the mortality ratio was 0.94 per 1000, against 0.01 in 1920 and 0.12 for the previous quinquennium. Every district throughout the province was affected, that of Kangra, in Jullundur division, having a death-rate of 7.5 per 1000, and in the town itself, 15.92 per 1000; in the small town of Dasuyah, in Hoshiarpur district, the mortality was 34.2 per 1000. The province was entirely free during the first three months of the year; the epidemic commenced in April, reached its climax in September (when there were 7279 deaths), and practically came to an end in October. The disease was introduced in April by a man coming from an infected house in Delhi to the Gurgaon district, but did not spread owing to prompt action by the district M.O.H. Later in the month infection was again introduced by pilgrims returning from Hardwar to Kangra. "The epidemic emphasises the necessity for a district preventive staff. Given prompt information of an outbreak, and the staff necessary to deal with it, cholera can be easily checked." More district medical officers are required.

As regards sanitary works in general there is not much to be recorded. "On the whole, it may be said that the policy of framing rules and regulations for villages is the failure it deserves to be. . . . The villagers do not want rules and regulations, and in this respect do not differ from any other rural population. They do want material

assistance, which it is within the power of the district boards to give. Instead of framing rules the district boards should concentrate on the policy urged by the sanitary board—a district health agency, and a standard of one dispensary per ten square miles. . . . The rural water supplies in large areas of the province are in a deplorable state, and the sanitary board has the utmost difficulty in getting projects put forward for the improvement of this state of affairs." This appears to be rather pessimistic; on the other hand, a long list of works of public utility, constructed by private individuals at their own expense, shows that there exists a very great deal of public spirit among, at any rate, some classes in the province, which deserves, and, no doubt, receives due recognition.

CANADIAN MEDICAL DIRECTORY, 1923.

The sixth edition of the Canadian Medical Directory contains over 450 pages of text, and is divided into three parts. The first part deals with information concerning the reciprocity of medical licences between Canada and Great Britain, the Medical Council of Canada, and the Canadian Medical Register; the universities of the Dominion; Soldiers' Civil Re-establishment Hospitals; agencies for diagnosis and treatment of tuberculosis; and physician-coroners and specialists in the various provinces. The second part contains, under a heading for each province, full particulars of medical laws and regulations, lists of colleges, departments of public health, hospitals, sanatoriums, &c., and medical associations and medical journals, together with place lists of physicians, surgeons, druggists, and dentists. The third part comprises alphabetical indexes of all names of physicians, surgeons, and dentists, and general lists of veterinary surgeons, opticians, chemists, chemical companies, dental laboratories, and dental supply manufacturers, &c., in Canada and Newfoundland.

CAMPAIGN AGAINST MALNUTRITION IN AMERICA.

A PAMPHLET prepared by an Advisory Committee on Foods and Nutrition of the National Child Health Council has just been issued as a bulletin by the United States Public Health Service (Bulletin No. 134, 1923). It is the outcome of a study into the incidence of malnutrition amongst children in the U.S.A., the principal causes of malnutrition being discussed, and suggestions being made for preventive and corrective measures. Among the common causes of malnutrition are mentioned physical defects, such as nasopharyngeal obstructions, carious teeth, and other more serious conditions. In many instances the correction of such physical defects is all that is necessary to give a child the chance to develop normally. Other causes are improper diet and faulty health habits, lack of home discipline, faulty posture associated with over-fatigue, inadequate and unsatisfactory sleeping accommodation, as well as more general community conditions—bad housing, insanitary school buildings, atmospheric contamination, and the like. Suggestions for a campaign to combat malnutrition include: (1) Preventive nutrition work, as part of a programme of health education for all normal children of school age; (2) corrective work for school children who are physically subnormal and in need of special attention; (3) nutrition work with children under school age, both normal and subnormal.

Special emphasis is laid on the value of work among children of pre-school age, which should tend to reduce the necessity for corrective measures among school-children. In addition to thorough health examinations and medical supervision, home visiting is regarded as vital, the visits working with the mother, and helping her to correct unfavourable conditions. It is recognised that the problem in rural districts presents different features from that in cities, and suggestions are made by which local interest may be aroused and local service enlisted. The pamphlet may be studied with profit by all those who are working on cognate lines in this country.

Messrs. William Heinemann (Medical Books), Ltd. will shortly publish "Aromatics and the Soul," by Dr. D. McKenzie and "The Hygiene of Marriage," by Mrs. I. Hutton, M.D.

By a regulation dated May 16th the Home Secretary has revoked No. 1 of the Dangerous Drugs Regulations, 1922 (S.R. & O. 1922, No. 1087), which provides that a prescription for dangerous drugs may not be given for the use of the prescriber himself.

Circular 325, dated July 17th, 1922, with reference to prosecutions for selling milk deficient in fat, has been withdrawn by the Ministry of Health. This circular has not produced the effect which was intended, and the Minister expresses its reliance on the responsible local authorities to administer the Sale of Food and Drugs Acts with fairness and consideration.

The Linacre Lecture

ENTITLED

GLIMPSES OF THE HIGHER MEDICINE.

Delivered at Cambridge on May 5th, 1923,

By ARCHIBALD E. GARROD, K.C.M.G.,
D.M., LL.D., F.R.S., F.R.C.P.

REGIUS PROFESSOR OF MEDICINE IN THE UNIVERSITY OF OXFORD;
CONSULTING PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL
AND TO THE HOSPITAL FOR SICK CHILDREN.

To me, as a member of a university which numbers Thomas Linacre amongst her honoured sons and benefactors, the invitation to deliver the lecture which he founded in the sister seat of learning is a great honour and privilege, for which I offer my sincere thanks to the Master and Fellows of St. John's College.

Those of us who entered upon the study of science 50 years ago have lived through stirring times. We have witnessed not only a rapid growth of natural knowledge, but also profound changes of outlook. We are like crater-dwellers who have climbed, step by step, the enclosing heights, and look over the edge upon unexplored regions beyond. Conceptions which seemed to be founded upon solid rock have been shown to be unstable, and a new and not merely a more ample science has come into being. The rigid and immutable atom has been revealed as a microcosm, a storehouse of energies which we can neither utilise nor control. Even Newton's laws no longer suffice; space is awry and all is relative. A new and higher chemistry deals with such phenomena as radio-activity and atomic degradation; with new entities such as emanations and isotopes. The barriers between chemistry and physics are broken down, and by the study of the properties of colloids we may hope, in the end, to solve the riddle of life. The higher biology, which had its beginnings with Darwin, Wallace, and Huxley, with Mendel and Francis Galton, is becoming permeated by chemistry and physics, and has become an experimental science as well as a science of observation.

We, too, who pursue the science of medicine are looking over the edge, have entered upon new and unfamiliar ground, and have obtained glimpses of a higher medicine. By far the most important factor in this change of outlook has been the growth of bacteriology and protozoology. These have revealed the actual agents which produce disease, the ways in which they are conveyed to and enter the organism, and are bringing to light the phenomena of immunity. Moreover, they supply us with new methods by which to combat disease, and have rendered possible the triumphs of preventive medicine and aseptic surgery. Only those who lived in the days before bacteriology can realise the revolution in medical thought which it has brought about, and even they fail to realise it fully, so gradually have they adapted themselves to each fresh advance of knowledge.

A second potent factor has been the progress of biochemistry, the science which reveals the composition of the living tissues, the nature of the metabolic processes of which they are the seats, and the disturbances of those processes which are wrought by disease. We have been taught to think of pathology in terms of the cell, but we are learning to think of it in terms of the molecule. As was foreshadowed by Herbert Spencer many years ago, and as has been urged in recent years by various authors, it is not in so highly organised a structure as the cell that we should seek for the beginnings of life, but rather in the molecule so complex and unstable that, in a suitable colloidal environment and in the presence of catalytic agents, it breaks down and is reconstructed.

It is between the active and inactive molecule that the unbridged gap exists rather than between the unicellular organism and the elephant or tree, which are but nations of specialised cells. Only the molecules of proteins possess the required complexity and instability, and all evidence points to the proteins as the vehicles of life.

It is hardly needful nowadays to argue that animals and plants of different genera and species differ in their chemistry as they do in their structure. This idea, although it is not much older than the present century, is already widely accepted by biologists, and permeates the most recent literature of their science. Their acceptance of it is mainly based upon the results of the so-called biological tests, the precipitin reaction and the phenomena of protein shock. But we have no need to rely upon such ultra-chemical evidence alone, for strictly chemical methods provide ample proofs of its truth. Some such evidence was brought together by the late Prof. Huppert, of Prague, in a masterly Rectorial address delivered in the year 1896. That address, which had for its title "Die Erhaltung der Arteigenschaften," was published only in pamphlet form, and is not easily accessible, which is unfortunate, seeing that it contains not only one of the earliest, but also one of the most suggestive and convincing expositions of the theme.

It is a well-known fact that the hæmoglobins of animals differ in crystalline forms, and Rollet showed that when the laked blood of a squirrel is mixed with that of a mouse the squirrel and mouse hæmoglobins crystallise out in their characteristic forms. Reichert and Brown also detected minor differences of crystalline behaviour in the hæmoglobins of closely allied species, and differences of iron content have also been shown to exist. Presumably the differences lie in the complex globin, and not in the comparatively simple hæmatin. That the fats of different animals differ in composition is also well known, but a foreign fat can be stored and utilised. The tissues of higher animals contain the same elements, combined in various proportions, but amongst the invertebrata other elements are met with, such as copper in the hæmocyanin of crustaceans and molluscs. Nor is this true of invertebrata alone, as witness the presence of copper in the red pigment of the feathers of the plantain-eaters, which has such strange affinities with hæmoglobin and hæmatin.

Not only are the materials of which the tissues are composed generic or specific, but also the products of the metabolic processes. Evidence of this is afforded by the specific bile-salts of certain mammals, and by the wide differences in the proportions of the various purin substances in the excreta which have been described by Andrew Hunter, by the presence of cynurenic acid in the urine of animals of the canine tribe, by the sepia of the cuttlefish, and the mephitic odour of the skunk. The vegetable kingdom also affords very many examples, but those which have been quoted must suffice.

The teasing out of the protein molecules, by Emil Fischer and those who have carried on his work, has revealed possibilities of almost infinite variety in the groupings and proportional representations of the 20 odd amino-acids and diamino-acids of which the protein molecules are built up. The possible arrangements in which each such fraction is represented once and only once exceeds a million millions, and if we allow for the fact that some proteins are poor and some are rich in particular fractions, and that in others some amino-acids are not represented, it is obvious that we are confronted with figures such as those with which astronomers deal. We may well believe that there are special proteins for every species, and indeed for every individual in a species. We cannot doubt that in such compounds the specific differences mainly lie, and even if certain highly specialised proteins, such as those of the crystalline lens, are common to many species, that does not invalidate the general law. In this connexion the precipitin test is of very special value, for it shows that the more nearly

genera or species are allied, the more closely do their proteins approximate.

To a large extent bodily form and chemical structure go hand in hand, and the view that the form of an animal or plant is determined by its chemical constitution is now held by not a few biologists. But how this comes about is as yet an unsolved problem. The relation of crystalline form to chemical composition offers an obvious analogy, but one which must not be stretched too far. It is a far cry from the cube or octahedron to the webbed foot of the duck or to the highly specialised hand of man. Leduc approached the problem by the study of the forms produced by osmosis, which often bear such weird resemblance to animal and vegetable structures, and others have sought for clues in the workings of the endocrine glands, some of which have a remarkable influence on bodily form. But it seems to me that the strongest argument that can be adduced in support of the hypothesis that bodily form depends upon chemical structure is based on the fact that the germinal cells of different animals, which resemble each other so closely in structure, and even the chromosomes of their nuclei, obviously include factors which determine both the forms and metabolic peculiarities of the organisms which originate from them.

If it be the fact that genera and species are chemically diverse, it must also be the case that the diversity extends, in some degree, to the individual members of a species. Although strictly chemical evidence of such individual differences are not yet forthcoming, they nevertheless reveal themselves in various ways. The need for the selection of blood from donors of a particular group, if transfusion is to be carried out with success, is a case in point; and further evidence is afforded by personal idiosyncrasies to special foods and drugs, by the colours of skin, hair, and eyes, and by individual liabilities to, or immunity from, certain infective maladies. We may easily suppose that when divergence exceeds a certain limit, sterility may result from incompatibility of the germinal proteins, and that in this way specific characters become established, and the characteristics of the species are preserved.

It must needs be difficult to distinguish small deviations from the normal metabolic scheme of a species from the innumerable disturbances which disease brings in its train, but there are met with in rare cases gross variations which are obviously congenital. These inborn errors of metabolism, such as alcaptonuria, cystinuria, and hæmatoporphyria congenita, are in a high degree hereditary, and behave, for the most part, as Mendelian recessive characters. We can hardly doubt that those which we know are only samples of a much larger group, and attract attention because they advertise themselves in conspicuous ways. The more closely these errors are studied, the more probable does it appear that in each instance the fault lies in the failure of a special enzyme, which is responsible for some particular step in normal metabolism. It would appear that the individual protein fractions, or groups of closely akin fractions, such as tyrosin and phenylalanin, are dealt with in successive stages by appropriate enzymes. If one step is missed the intermediate product in being is excreted as such, or in a slightly altered form. If, however, the default be at an early stage of catabolism, and a process such as desamination, which is common to all the fractions, be involved, a wider effect is produced. Thus in cystinuria various amino-acids may be excreted in addition to cystin, and all without the loss of their amino groupings. In alcaptonuria, on the other hand, only tyrosin and phenylalanin are implicated, and the other protein fractions are dealt with in the ordinary way.

If it be granted that the individual members of a species may vary from the normal of the species in chemical structure and chemical behaviour, it is obvious that such variations or mutations are capable of being perpetuated by natural selection; and not a few biologists of the present day assign to chemical

structure and functions a most important share in the evolution of species. This aspect of evolutionary thought was emphasised by Prof. Goodrich in his address to the Zoological Section of the British Association in 1922.

We may picture each cell of a living organism as a seat of intense chemical activities. In it are carried on processes of oxidation and reduction, of destruction and reconstruction, side by side and without any mutual interference. The study of colloidal chemistry is helping to throw light upon these marvellous intracellular activities, and upon the enzyme actions by which they are brought about. If left uncontrolled, these processes would run riot, and it is obvious that all the processes in the living organism are under efficient control. In no other way can be explained the average height and weight of human beings, the uniformity of the body temperature, the standard blood pressure, and the more or less uniform output of the various end-products of metabolism. It is equally obvious that the control is exquisitely adaptable to changes of the external temperature, to the needs of the growing organism, and to the conditions present in disease. Such a control cannot be one-sided, and involves a balance of opposing factors.

In the more recent years we have learned much concerning the mechanism by which this is effected. The agents of control are the hormones produced by the endocrine glands, chemical compounds of no great complexity. Two such hormones have been isolated. The nature of adrenalin and of thyroxin has been investigated by strictly chemical methods, their composition is established, and the synthesis of adrenalin has been effected. The endocrine glands are themselves under the control of the sympathetic nervous system, and the control is to some extent automatic. The supply of a hormone is regulated by the demand, as is the gas-supply of an incubator. There is much evidence which points to a balance of the endocrine glands, some of which coöperate whereas others secrete antagonistic hormones. We may picture them as a system of weights and pulleys, in stable equilibrium, in which removal of any one weight causes the whole system to hang awry.

The periods of activity of some of the endocrine glands covers only a part of the life-time of the individual. The thymus soon goes out of action, and there is some evidence that the pineal ceases to function at puberty. At puberty also the gonoids become active and cease to function at the menopause. The phenomena of puberty may be regarded as signs of the readjustment of the endocrine balance, as also may those of the menopause. The enlargement of the thyroid which is so common in girls at puberty, and the obesity which so often follows the menopause, are minor indications of these readjustments.

Clinical observation reveals conspicuous differences between the organism of the child and that of the adult. Some maladies occur only in children, and others which attack individuals of all ages present widely different clinical pictures in adults and children respectively. The lesions produced by the tubercle bacillus and the pneumococcus differ in their seats and characters in children and adults, and—to select a specially striking example—rheumatic fever in a child is very unlike the same disease in an older patient. Such differences supply the justification for the erection of pædiatrics into a special branch of medical study. Some of these differences depend upon the immaturity of the tissues, and it would not be justifiable, in the present state of our knowledge, to attribute them to the changes in the endocrine balance, but they may well have a chemical basis.

The orderly sequence of metabolic changes which is at work in the normal organism is profoundly disturbed by the incursion of the agents of disease. Elaborate devices are called into play to destroy the invaders and to render inert their toxic products. Very often the invaders fail to gain a foothold and our natural defences avert from us many more such

attacks than we wot of. If a foothold be obtained the protective mechanisms may succeed in localising the mischief, and a local inflammation results, but from such a focus virulent poisons may, as in tetanus, be carried to remote parts of the body. Even if the local defences be broken down, and general infection results, the means of defence are not exhausted, the tissues often win the day in the end, the invaders are destroyed, and the patient recovers. The mobilisation of the phagocytes plays an important part, but some of the defensive mechanisms are frankly chemical, such as the neutralisation of acids by ammonia, and the combination of aromatic poisons with glycol to form the hippuric acids, or with sulphates to form aromatic sulphates, whereby they are rendered innocuous until they can be got rid of by excretion. Others are still beyond the reach of strictly chemical investigation, such as the formation of antitoxins and bactericidal substances, and the other substances which the modern study of immunity has revealed, but which are still seen "through a glass darkly." We cannot doubt that these protections are products of natural selection, for it is obvious that those organisms which are best armed against their natural enemies are the fittest to survive.

The discovery of these wonderful protective mechanisms has opened the eyes of those of us who pursue the science and art of medicine to the shortcomings of our own therapeutic methods, and the immense superiority of nature's drugs. We have come to realise that instead of commanding the forces engaged in the fight with disease, with the body of our patient as the battlefield, we are but his allies in the combat which he is himself waging against the enemies which assail and threaten to overwhelm him. In response to this lesson we try to make use of nature's own remedies, with results which are sometimes brilliant, and often encouraging, in spite of the defects of our technique. When the various protective agents have been isolated, so that we can give them in pure forms, and freed from extraneous substances which hamper their use, we shall be far better equipped than we are at present for the fight with disease.

The toxic substances are probably of several kinds. Some may be compared to the poisons which are formed by certain plants, such as atropine and strychnine. Others may, as Abderhalden suggests, be intermediate products of the breakdown of bacterial proteins, and others, again, the actual proteins of the main invaders, which produce the morbid effects common to foreign proteins in general. It is only in recent years that we have come to realise how important the part played by protein poisoning, and protein shock, in shaping the clinical pictures of various maladies, and not only of those which result from bacterial or protozoal infection. Serum sickness, which so often follows an injection of a serum after an interval of some days, is curiously reminiscent of syndromes which are produced by bacterial infections. Pain and swelling of joints, fever, and an erythematous or urticarial rash are its outstanding symptoms, and the association of lesions of the joints and skin are often observed in disease. The transitory arthritis of pneumonic fever and the erythemata which sometimes accompany it may possibly result from poisoning by bacterial proteins, and such influences may have a share in shaping the clinical pictures of the exanthemata.

Asthma offers the best known and most obvious example of a malady in which hypersensitiveness to foreign proteins plays a conspicuous part. The asthma syndrome may be caused by foreign proteins which gain access to the organism by way of the naso-pharynx, conjunctiva, or the mucous membrane of the alimentary tract. In some cases the provoking agent is a pollen, as in the familiar hay asthma, in others the hair or emanations of an animal, such as a cat, horse, or guinea-pig, and in yet others a food protein, such as casein or egg-albumin. The attacks may cease when the patient is protected from the exciting cause, or when he has been desensitised by

the administration of the peccant substance in small graduated doses.

We are probably justified in referring to the same cause certain periodic diseases in which the recurrent symptoms are such as foreign proteins are known to produce. Henoch's purpura is one of these, and erythemata sometimes recur in this way. But one of the most interesting and remarkable of such manifestations is the periodic swelling of the knees, and sometimes of other joints, which is known as intermittent hydrarthrosis. The attacks recur with almost mathematical regularity, so that the patient can make his arrangements in anticipation of their return. The interval varies in different cases, but is usually from six to eight days, and the duration of the attack is about three days. Joints which have been seriously damaged by any form of arthritis may be seats of the trouble, but more often the knees appear perfectly normal between the attacks, at least in the earlier stages of the complaint. That the articular structures are not primarily at fault is shown by the facts that the attacks almost always cease during a pregnancy, but recur after delivery, and that active local treatment of an affected joint may be followed by transfer of the attacks to the corresponding joint of the opposite limb. In some cases giant oedema of the lip or eyelid may recur with each articular attack. The easiest explanation of the regularity of recurrence is that each attack produces a temporary desensitisation of the patient.

The cyclic vomiting of children affords yet another example, and just as patients may grow out of their sensitiveness to a special protein food, so such cyclic vomiting usually ceases when the child grows older. Such maladies serve to illustrate a general law that whereas the intruding agents are the actual cause of disease, the reaction of the patient's tissues shapes the clinical picture.

Another potent factor in not a few diseases is disturbance of the balance of the endocrine glands. The study of the functions of these glands, which has been carried on by many observers since Addison published his classical monograph upon the disease, or rather syndrome, which bears his name, has opened up a most fascinating field of physiology and medicine. Nature's experiments and man's have thrown much light upon their several functions. They have revealed the influence of the thyroid upon metabolism as a whole, that of the pituitary upon growth and fat storage, that of the chromaffin tissues and posterior lobe of the pituitary upon blood pressure, and that of several of these glands upon carbohydrate metabolism. These are only a few examples of the manifold endocrine activities which may be thrown out of gear when these organs are damaged by disease.

Many riddles are still unsolved. We do not know what purpose is served by the apposition, in what is from the anatomical standpoint a single organ, of glands of widely different functions. The pituitary consists of two, if not three, such structures. Much of the chromaffin tissue is wrapped round by the adrenal cortex, and in higher animals what may be called the gland of Langerhans is scattered in fragments through the substance of that great digestive gland, the pancreas.

As I have already mentioned, some of the endocrine glands are obviously antagonistic in their functions, so that when one is thrown out of action its antagonist tends to run riot, whereas others appear to act in alliance. The familiar signs of myxoedema, cretinism, and cachexia strumipriva cannot obviously be attributed to the thyroid gland, the functions of which are in abeyance, but to the uncontrolled working of other endocrine organs which the normal thyroid holds in check. Fröhlich's syndrome, or dystrophia adiposo-genitalis, with its combination of obesity and regressive infantilism, results from destruction of the pituitary, just as myxoedema does from destruction or atrophy of the thyroid, but the pituitary is a far more complex organ, and cases of hypopituitarism do not conform to type nearly so close as do those of

hypothyroidism. Some of the patients with this condition are not obese and in others infantilism is not conspicuous. Both myxoedema and Fröhlich's syndrome are but extreme examples, and between these conditions and normality all degrees of hypothyroidism and hypopituitarism are met with.

The evidence that some of the endocrine syndromes are due to over-activity of the glands involved is far less conclusive, and some investigators whose opinions are entitled to the greatest respect lean to the view that such maladies as acromegaly and exophthalmic goitre are due rather to a perverted than to an exalted functional activity, that not merely an excess of the pituitary and thyroid hormones are produced, but a wrong kind of hormone. The hypothesis that acromegaly is the result of hyperpituitarism involves the assumption that an adenoma of a gland may increase the output of its secretory products.

Nevertheless, it appears to me that the evidence for the hypothesis of hyperactivity outweighs that which can be advanced in support of the alternative hypothesis of perverted function. And in this connexion a case recorded by Notthafft is of special interest. A man who wished to reduce his weight, took, on his own initiative and without medical advice, a thousand five-grain tablets of thyroid extract in the space of five weeks. He developed the signs of exophthalmic goitre of extreme degree—namely, tachycardia, exophthalmos with lagging of the upper eyelid, tremor, and, be it noted, enlargement of the thyroid gland. His urine contained sugar, and the average volume passed daily amounted to 3000 c.cm. After the drug was stopped the signs disappeared, the glycosuria after ten days, the tremor after four weeks, but the ocular signs and the swelling of the thyroid persisted for about six months. We can hardly escape the conclusion that the enlargement of the thyroid in this case was a part of a vicious circle. The thyroid is controlled by the sympathetic nervous system, whereas thyroxin stimulates the sympathetic, and so the conditions exist which are needed to ensure auto-aggravation of the disease.

In order to show the kind of evidence upon which the hypothesis of an endocrine balance rests, I propose to select one particular example of endocrine antagonism, and that not one of the most familiar. It may be called the thyroido-pancreatic, or, more accurately, the thyroido-Langerhans syndrome. There is good reason to believe that these two glands are antagonists, that over-activity of the thyroid inhibits the islands and vice versa. Thus the administration of thyroid extract induces glycosuria, most readily in normal individuals to whom any dose is practically an over-dose. Even patients with myxoedema may excrete sugar in the course of treatment, if the dose given be beyond their requirement, although, as is well known, their glucose tolerance far exceeds the normal limit. On the other hand, glucose tolerance is often lowered in cases of Graves's disease; some patients pass sugar intermittently, and some acquire a veritable diabetes. Some, again, as Falta showed, pass fatty stools and are found to have morbid changes in the pancreas.

Far less familiar is the reverse of the picture—namely, the tendency of sufferers from disease of the pancreas to exhibit signs of over-activity of the thyroid. The most conspicuous examples are afforded by cases in which diabetes and exophthalmic goitre co-exist, and in which it can be shown that the excretion of glucose preceded by a considerable period the appearance of the signs of hyperthyroidism. Some diabetics exhibit an incomplete thyroidal syndrome, usually limited to the ocular signs. I can myself recall several such cases in which the prominence of the eyeballs attracted attention and von Graefe's sign was pronounced, but in which, at least in the early stages, the pulse-frequency was normal or even below the normal. In some of these cases tachycardia developed as time went on.

Some years ago Cohn and Peiser described a series of cases of acute and chronic pancreatitis in which similar symptoms were observed. Of the cases,

five in number, three were of acute hæmorrhagic, one of suppurative, and one of chronic interstitial pancreatitis. Von Graefe's sign was elicited in four, Moebius's and Stellwag's signs were present in all, and also tremor and dermatography. The authors wisely decline to base any sweeping generalisation upon so small a number of cases, but since their paper appeared I have been able to confirm their observations in several cases of acute pancreatitis. In a condition of such gravity these signs are apt to escape notice, unless specially looked for, seeing that they are never pronounced. On the other hand, the high glucose tolerance of myxoedematous patients points to over-activity of the islands when the control of the thyroid is removed.

Glycosuria is a symptom of various endocrine diseases, and, when met with, it suggests a similar antagonistic action of hormones. In acromegaly glycosuria is not uncommon, whereas in hypopituitarism glucose tolerance is raised, as it is in myxoedema. Injection of adrenalin is often followed by glycosuria, and in Addison's disease tolerance of glucose has been found to be increased.

That diabetes, as distinguished from the conditions classed under the names of renal glucosuria or glycosuria innocens, is essentially an endocrine disease is shown by experimental and clinical evidence, and notably by the effect of insulin in cases in which, apart from glycosuria, there are no indications of lesions of the pancreas. The recent work of Winter and Smith, in this place, gives an indication of the way in which insulin works by preparing glucose for utilisation by the tissues. Obesity also, which is often classed, with diabetes and gout, as a disease of metabolism, is certainly in many, and probably in all cases, due to disturbance of the endocrine balance. It is a prominent symptom of hyperpituitarism, of tumours of the adrenal cortex, and of suppression of the functions of the gonads. Obviously, then, the influence of disturbances of the endocrine balance in shaping the clinical pictures of disease extend far beyond the cases in which one or more of the glands of internal secretion are seats of tumours or other gross lesions.

The normal, orderly course of metabolism is clearly dependent upon the supply of necessary substances from without the organism: of oxygen, water, and inorganic salts, of an adequate supply of fats and carbohydrates, and of proteins from the materials of which a sufficiency may be obtained of the various amino-acids which are required for reconstruction into the specific proteins. It is obvious that any lack of such supplies will entail disturbances of the metabolic processes, and that withdrawal of any important group of foods will have conspicuous effects, as witness the acetonaemia which results from withdrawal of carbohydrates.

We have learnt in recent years that a due supply in correct proportions, of foodstuffs of which the value can be reckoned in calories—that is to say, of proteins, fats, and carbohydrates—does not alone suffice for the promotion of growth and maintenance of nutrition. Other food factors which do not rank as foods, but rather as exogenous hormones, are equally essential. The discovery of these vitamins, of which it is most appropriate that I should speak in this place, has opened up new vistas, and affords illuminating glimpses of the higher medicine.

How far the lack of vitamins is responsible for the production of particular diseases is still a highly controversial question, and we have much to learn concerning their nature and modes of action. The study of the so-called deficiency diseases, which are believed to result from shortage of vitamins, raises once more the interesting question of the way in which a negative factor can give rise to positively morbid changes. This question was already raised in connexion with myxoedema and Fröhlich's syndrome, and was met by invocation of the endocrine balance; but in deficiency diseases there is, as far as we know, no such balance to be invoked. We

must rather suppose that, to quote the words of McCarrison, "persons receiving too little vitamins are living in a state of potential morbidity, which may be converted into one of actual disease by a variety of factors that further exhaust metabolism." Amongst such factors are enumerated cold, damp, mental depression, overcrowding, and infective agents. Age, sex, personal idiosyncrasies, also play parts in the production and shape of deficiency diseases. Time will not permit me to discuss the various maladies which have been included in this class, nor their signs and symptoms, which embrace lesions of the bony structures and nervous system, oedematous swellings and lesions of the corneæ, nor to consider the parts played by external influences in their causation. I will therefore limit my remarks to scurvy, which may, without hesitation, be classed as a deficiency disease.

The influence of immaturity of the tissues is very conspicuous in that disease. The clinical picture of infantile scurvy, with its subperiosteal hæmorrhages, the exophthalmos which results from orbital hæmorrhages, and the exquisite tenderness which is one of its earliest symptoms, is so unlike that of the adult variety that continental observers long hesitated to include Barlow's disease in the scorbutic category. But the prompt response to antiscorbutic treatment leaves no doubt as to its nature. It is not improbable that the cutaneous hæmorrhages may be provoked by such slight traumatic influences as pressure on a part, and one is tempted to attribute the condition of the gums in young children to the cutting of the teeth. Undoubtedly scorbutic infants who have no teeth escape the lesions of the gums, save that they are seen over teeth which are on the point of eruption. In older infants the swelling and purple colour are limited to the neighbourhood of such teeth as have been cut. But no such explanation applies to the puffy gums of adults, and if this condition might be attributed to the sepsis which is so often present, sepsis cannot explain the affection of the gums over the teeth of infants which have not yet penetrated to the surface.

In pellagra, which also is probably a deficiency disease, the skin affection, from which that malady derives its name, recurs each year with the return of brighter days, and apparently has its exciting cause in some form of radiant energy, such as light or ultra-violet rays. Light undoubtedly exerts a profound effect upon living organisms, and, as is becoming more and more recognised, it is one of the potent external factors which influence disease. The subject has many aspects, as, for example, the protective action of surface pigmentation, the therapeutic value of protection of patients with small-pox from actinic rays, and the curative and bactericidal effects of light and ultra-violet rays. But here, as before, I will select one particular aspect—namely, the share of light in provoking lesions of the skin—which raises questions of special interest to physicians and chemical pathologists alike.

Hydroa vacciniforme is a rare form of bullous eruption which recurs in successive summers, and is confined to those surfaces of skin which are exposed to light. After each return the affected skin is left more and more severely scarred, affection of the conjunctivæ and corneæ may produce blindness, and the serious effects are loss of substance of the nose and ears and deformities of the hands. In some cases the patients have passed, from birth onwards, red skin which owes its colour to a pigment closely allied to, but not identical with, hæmatoporphyrin. This syndrome is apt to occur in several members of a family, and the porphyrinuria is evidently due to an inborn error of metabolism. In some cases the dark urine does not date from birth, but has been passed for months or years.

Tappeiner and Raab found that certain fluorescent pigments, of which eosin is one, sensitise such organisms as *Paramecium* to light. When a culture of *Paramecium* in water to which some such pigment has been added is in part exposed to, and in part shaded from, light, the organism is killed in the exposed

portion, but not in that which is shaded. Walther Hausmann showed that hæmatoporphyrin, which is a fluorescent pigment, has this power, and further, that when a white mouse receives a subcutaneous injection of 0.02 g. of hæmatoporphyrin it dies rapidly if exposed to light, but shows no ill-effects if kept in the dark. If, on the other hand, it be exposed to feeble light a chronic light disease is produced with purple swelling of the snout and ears leading on to necrosis, loss of hair, and other symptoms. The effect of the injection is only temporary, and if the animal is kept in the dark for a sufficient time, subsequent exposure to light does no harm. By a bold experiment upon himself, Meyer-Betz showed that similar effects are produced in human subjects. An intravenous injection of 0.2 g. of the pigment rendered him sensitive to light for three months. Bright light caused giant oedema, with pigmentation of excessive degree and other symptoms. More recently Howell has shown that fibrinogen also undergoes remarkable changes when exposed to light in contact with hæmatoporphyrin, and suggests that the pigment acts as a catalyst.

The metabolic porphyrins of urine and fæces, which have been thoroughly investigated on chemical lines by Hans Fischer, have similar, although less pronounced effects. In congenital porphyrinuria the presence of porphyrin in the tissues is shown by deep-brown pigmentation of the bones, and in some cases of the enamel of the teeth. Thus we are confronted by the fact that certain individuals who have in their tissues a pigment of proved photo-sensitising properties are prone to develop an affection of the skin which is obviously produced by exposure to light, and we cannot escape the conclusion that the presence of the pigment and exposure to light are jointly responsible for the cutaneous lesions. However, the matter is not so simple as appears at first sight. In some cases of life-long porphyrinuria there is no hydroa, and in some cases light appears to provoke both porphyrinuria and hydroa. Into the probable explanations of these discrepancies I cannot enter here. But allusion must be made to the fact that whereas Hausmann found that rays in the neighbourhood of 5000 were most active in producing symptoms in injected animals, it has been shown by Freund and others that actinic rays are the most potent in production of the lesions of hydroa. It is highly probable that in not a few cases of hydroa photo-sensitising substances other than a porphyrin are at work, but of these we know nothing as yet. This story of porphyrinuria and hydroa offers an excellent illustration of interaction of internal and external factors in the production of a characteristic clinical picture.

Another such example is afforded by cystinuria. Cystin is a substance eminently suitable for the formation of urinary calculi, and most cystinurics form such calculi sooner or later. But some escape such troubles, and it is probable that the exciting cause of calculus formation is an infection of the urinary tract, such as so commonly occurs.

Very few individuals exhibit such striking deviations from normal metabolism as porphyrinurics and cystinurics show, but I suspect strongly that minimal deviations which escape notice are almost universal. How else can be explained the part played by heredity in disease? There are some diseases which are handed down from generation to generation, which manifest themselves by no signs at birth or in infancy, but which tend to develop in later childhood or early adult life. Unlike congenital anomalies, they are progressive. Pseudo-hypertrophic muscular dystrophy is such a malady, as also are certain diseases of the nervous system such as Friedreich's ataxia, and myotonia congenita or Thomsen's disease. It is difficult to escape the conclusion that although these maladies are not congenital, their underlying causes are inborn peculiarities.

In support of this contention I may quote a remarkable malformation complex, of which a number of cases are on record, and of which, by the kindness of Dr. W. Stobie, I recently had an opportunity of seeing

a number of cases in members of a single family, and in several generations thereof. The association of blue colour of the sclerotics with fragility of bones was first described by Eddowes, and these conditions, which form the basis of the syndrome, are probably due to defective development of the fibrous tissues. The thin sclerotics allow the pigmented choroid to show through them, and hence their blue tint. In some six or seven of the affected families, including that which Dr. Stobie will record, there has been present a third factor—namely, progressive deafness due to oto-sclerosis—and this is confined to the abnormal members of the families in question. But the oto-sclerosis is not present from birth. It develops in later childhood or more often in early adult life, and gives rise to increasing deafness. It is characterised by lesions of the structures of the ear, one of which is fixation of the stapes by ankylosis.

Here, then, we have an acquired hereditary disease which occurs in intimate association with two congenital anomalies. If any external factor is its exciting cause we do not know, as yet, what that factor is.

Gout holds an intermediate position between the heredity maladies of early life and the diseases of elderly people. That it is hereditary in a marked degree has been shown for many centuries, as is evident from the letter in which the younger Pliny describes the death of his friend Corellius Rufus, who was a great sufferer from gout. The pathogeny of gout is still obscure, but even if the accumulation of uric acid in the blood be due to a defect of excretion, it may be that, as Minkowski first suggested, and as Gudzent holds, it is the uric acid which is at fault, and is present in an abnormal form or combination. An acute attack in a joint may be brought on by an indiscretion of diet or by a trifling injury. Even so slight a trauma as the syringing of an ear may provoke an acute attack in the pinna of a very gouty man. The liability of the tarso-metatarsal joint of the great toe is probably due to the insults to which that joint is constantly subjected. Articulations which are seats of lowered resistance, such as those which have suffered injury at any time, or those of paralysed limbs, are especially apt to suffer.

A member of a family in which the disease was previously unknown may develop gout under the influence of a sedentary city life, and a member of a gouty family may fail to escape it despite the strictest temperance in all things. The geographical distribution, racial incidence, and waxing and waning frequency of this malady suggest that many influences still unknown are concerned in its causation.

The diseases of the elderly, such as granular kidney, arterio-sclerosis, and osteo-arthritis probably have their exciting causes in the innumerable minimal insults to which the tissues, even of those who lead the most prudent lives, are subjected. They show some tendency to attack the members of certain families, but the hereditary element is not nearly so obvious as in gout. By osteo-arthritis I mean the insidious disease of one joint or many, met with in elderly people, which causes erosion of cartilages and osteophytic outgrowths around the articular surfaces. It shows itself clinically in the form of Heberden's nodes, malum coxae senile, and similar affections of other parts. The onset of osteo-arthritis of the hip-joint is often ascribed to an injury, and there is much evidence that ordinary wear and tear is a potent exciting cause of such changes, but these causes do not suffice to bring about such a sequence of progressive lesions of the articular structures, and there must be another underlying cause. That in some cases this is an error of metabolism the arthritis of alcaptonurics shows. The subjects of alcaptonuria fail to complete the catabolism of the tyrosin and phenylalanin of food and tissue proteins, and there circulates in their blood, and is excreted in their urine, an aromatic compound, homogentisic acid. Owing to its presence the urine reduces Fehling's solution and blackens on exposure to air.

As the years go by, but seldom before the lapse of 30 years, the cartilages of the alcaptonurics become blackened, and an unusual rigidity of the cartilages of the ears suggests that they undergo some structural change. This condition, to which Virchow gave the name of ochronosis, is manifested clinically by a blue tint in the hollows of the ears, where the black cartilages show through the skin, by brown patches upon the conjunctivæ, and sometimes pigmentation of the skin. Later still, such patients are prone to develop osteo-arthritic changes in many joints, both of the limbs and spine. Their stature is apt to be reduced, partly owing to kyphosis, but largely as a result of absorption of the intervertebral discs, and they develop a peculiar gait and stance. The association of the articular lesions with ochronosis is certainly not an accidental one. The clinical picture is characteristic and in a family which includes several elderly members with alcaptonuria and ochronosis, as in one described by Ueber and Bürger, all the ochronotic members may exhibit lesions of the joints and spine, from which the normal members remain wholly free.

All the evidence which I have laid before you in this lecture, and much additional evidence besides, tends to show that many factors are concerned in the causation of disease and in the shaping of its clinical pictures. Environment, that is to say healthy or unhealthy surroundings, atmospheric conditions, and personal hygiene, tend to favour or discourage the prevalence of maladies. The invasion of the organism by bacteria or protozoa, and the introduction of chemical poisons by way of the alimentary canal or respiratory tract are the essential causes of most diseases, and rank first in order of importance. Other external influences, such as traumata slight or severe, light and other forms of radiant energy, heat and cold play no unimportant parts. Lastly, negative external factors such as deprivation of essential foodstuffs or vitamins and insufficient supply of oxygen, are potent causes of disease.

But in addition to all these there need to be taken into account factors inherent in our patients. Susceptibilities or immunities which may be inherited from their forebears, or may be widely distributed in members of their race. In a mixed population, such as ours, the influence of race is much obscured, but the Jews, who although scattered amongst alien peoples have kept their race pure, have preserved their racial immunities and liabilities, and even their special tendency to certain inborn anomalies, such as pentosuria and Warren Tay's syndrome. Nor is evidence lacking that such peculiarities may originate de novo in an individual, but proof of this is difficult, seeing that a recessive characteristic may lie latent through generations.

Thus we are led back to something very like the doctrine of diatheses which was so much in vogue in the days of our grandfathers, but has fallen into disrepute, and finds little or no place in the medical teaching of to-day. Nor, if we read the literature on the subject, can we wonder that this is so. The doctrine came to the birth prematurely, and many of the arguments adduced in its support appear futile in the light of newer knowledge. Some of the definitions of the term are woefully obscure, and whereas for one author a diathesis was merely predisposition, for another it was a sort of chronic disease. In the "New English Dictionary" diathesis is defined as "a permanent (hereditary or acquired) condition of the body which renders it liable to certain special diseases or affections; a constitutional predisposition or tendency." In this limited sense, I, for my part, am compelled to admit the truth of the doctrine.

It has been one of my chief aims, in this discourse to show that such predispositions exist, and, moreover, that they have their origin in deviations from the normal metabolic scheme of the species. In short, diathesis is only another name for chemical individuality.

EMPYEMA IN THE FIRST TWO YEARS OF LIFE,

WITH A DISCUSSION OF THE VALUE OF IMMEDIATE RESECTION OF RIB.

By HECTOR CHARLES CAMERON, M.D. CAMB.,
F.R.C.P. LOND.,

PHYSICIAN IN CHARGE OF THE CHILDREN'S DEPARTMENT,
GUY'S HOSPITAL;

AND

A. A. OSMAN, M.R.C.S. ENG.,
CHIEF CLINICAL ASSISTANT.

THAT empyema as a complication of acute pneumonia in the first two years of life has a distressingly high mortality has not escaped attention. Holt¹ quotes a series of 204 cases from the Infants Hospital of New York with a mortality of 74 per cent. in the first year of life and of 59 per cent. in the second. Many other similar statistics have been published, showing a mortality of about 60 per cent. for children under two years of age. After the third year the mortality falls to a very low figure. Reference to a large number of text-books, both of general medicine and of diseases of children, shows, however, that this high mortality in little children excites little comment or passes altogether unnoticed. As a rule it is suggested that a fatal result is due to delay in undertaking operation, to an unfortunate choice in the situation of the opening made into the pleura, to the pus becoming inoculated, or to failure of the lung to expand. The general impression conveyed is that such accidents are unusual and that recovery may be confidently expected. We have made a careful examination of the records of all cases of empyema in children under two years of age admitted into the medical wards of Guy's Hospital during the years 1911-20 inclusive. In all 52 cases were admitted, of which 13 recovered and 39 died. 11 of the 13 which recovered and 20 of the 39 which died were submitted to the radical operation of resection of a rib. In 19 cases no operation was performed, either because the child was thought to be too ill or because the diagnosis was not made during life. Examination of the history of these cases, we think, explains the discrepancy in the statement as to the prognosis in empyema. When empyema alone was present recovery invariably took place. The high mortality is not to be attributed to the failure to achieve satisfactory drainage or to any of the mechanical difficulties mentioned above. The infants died not of the empyema, but of the generalised pneumonic infection which preceded and persisted after the formation of the empyema.

Meta-pneumonic Empyema.

Of the 13 cases which recovered 12 were examples of what may be called in this sense *meta-pneumonic empyema*. That is to say, the empyema at the time the successful operation presented itself as a residual abscess in the pleura after the termination of the acute pneumonic process. The high mortality in infancy is due to peculiarities of the acute primary pneumonia of infancy, which, from its longer course and greater tendency to generalised infection of parts remote from the lung, seldom produces the meta-pneumonic type of empyema. It is always a favourable symptom when the rise in the temperature curve due to empyema is separate from and follows after an interval the rise due to the original pneumonic infection. This disposition, which is the rule with the short-lived lobar pneumonia of adults and older children, is, unfortunately, the exception with infants. In them, as a rule, the two curves are, as it were, superimposed one upon the other, and the empyema must be described as *syn-pneumonic*.

High Recovery Rate in Meta-pneumonic Empyema of Infancy Treated by Operation.

Of 13 cases which recovered 12 were meta-pneumonic, only one was syn-pneumonic. Of 39 cases which died, no statement can be made in five, either because

the clinical or post-mortem notes are deficient, or because the course of the case was unusual and difficult to interpret. Of the remaining 34 which died, all were definitely syn-pneumonic. No meta-pneumonic case died. In only two of the 12 meta-pneumonic cases (Cases 11 and 12) was almost the whole time of the illness spent in hospital under observation, so that the temperature chart records the initial pyrexia due to the pneumonia and later the irregularity of temperature due to the empyema. The other cases had passed through the original pneumonia and were admitted suffering from the residual empyema. In three cases long periods—three, five, and six months respectively—had passed since the pneumonia. In five cases the history was very indefinite, and though it was clear that the child had been ill, and was still ill, a definite diagnosis of pneumonia had not been made. All cases in this group, however, were alike in this, that they showed no symptoms of pneumonia at the time when the diagnosis of empyema was made. High temperature, rapid pulse, urgent and distressed breathing, cyanosis, delirium, meningismus, expressionless facies, &c., formed no part of the picture. Nor was there a history of a recent and sudden onset of pyrexia. The symptoms of the meta-pneumonic empyema were less striking. The mothers, as a rule, complained of the child's wasting, of an alteration for the worse in appetite, energy, and temper, of pallor, of a persistent dry cough, or of intermittent attacks of diarrhoea. When it had been recognised that the child had suffered and recovered from an attack of acute pneumonia, these indefinite symptoms were always dated from that attack and were regarded as an unsatisfactory convalescence from it. Examination showed a fretful, pale, wasted child with a normal or but slightly irregular temperature, who became dyspnoeic only upon exertion or after crying. In our series all of these quiescent meta-pneumonic cases recovered. All the others but one died.

Heavy Mortality from Syn-pneumonic Empyemata.

Of the 39 cases which died none was of the quiescent meta-pneumonic type described above. The interpretation of five (Cases 31, 32, 50, 51, 52) was difficult. The notes are appended without comment. The remaining 34 cases may be classed as definitely syn-pneumonic. In two of these the post-mortem reports are missing. Pneumonia, more or less extensive, is reported at the autopsy in 23 cases, acute or suppurative pericarditis in 10. One case had suppurative meningitis, one suppurative peritonitis, presumably of pneumococcal origin. In only one case (Case 33) was none of these fatal conditions present—the case of a young infant who died, a few hours after the resection of a rib upon the seventh day, of an acute streptococcal infection marked by high pyrexia and very rapid pulse. Acute pleurisy only was found, and there was no pneumonia and no pericarditis.

Effect of Operation in Syn-pneumonic Cases.

In the two indeterminate cases (Cases 31 and 32) which were submitted to operation the report records some temporary improvement as following the operation. For that reason they have not been classed as syn-pneumonic. In all but one of the 19 syn-pneumonic cases submitted to operation the clinical reports record either the absence of looked-for improvement or death within 24 hours. We believe that a comparison of the histories and charts of these syn-pneumonic cases with those of the meta-pneumonic cases, which all recovered, might have enabled this ill-result to be predicted with confidence. One of us, knowing nothing of the other circumstances of the cases, was enabled in almost every instance to state whether recovery or death had been the result by a glance at the record of temperature, pulse, and respiration during the first days in hospital, or, when immediate operation had taken place, by noting the single record of temperature, pulse, and respiration made at the moment of admission. Moreover, it is to be noted that of 19 cases operated upon, in nine death followed within 24 hours of operation. Nine died at varying intervals later. Case 13 is the only exception—the one

example of a case apparently syn-pneumonic which recovered after operation on the twenty-sixth day of the pneumonia. It is possible that the termination of the pneumonic process and the operation here coincided.

Period for Performance of the Radical Operation.

We think that it is clear that all meta-pneumonic empyemata should be submitted to operation as soon after the termination of the pneumonic process as possible. Delay from failure to recognise the presence of the residual collection of pus adds greatly to the risk of fibrosis and bronchiectasis in the lung involved, while after six or eight weeks there is an increasing risk that a fistulous communication with a bronchus may form. In meta-pneumonic cases the removal of the rib gives very free drainage and appears to be without risk.

We think it is equally clear that syn-pneumonic cases ought not to be operated upon by removal of a rib and with an anæsthetic until the termination of the pneumonic process. If pus in considerable quantity is present it should be removed by aspiration or continuous drainage, leaving the more radical operation to be performed later if necessary and if the child survives the pneumonia. If the syn-pneumonic cases are operated upon it appears that the mortality approaches 100 per cent. and that many of the deaths follow immediately upon the operation. As in the not dissimilar case of primary pneumococcal peritonitis, in which immediate laparotomy during the septicæmia is without benefit and may be followed by immediate death, the selection of the appropriate time for opening the residual abscess is the chief part of successful treatment.³

Causes of Death from Empyema in Young Infants.

It seems clear that the high mortality in young infants is not due to the presence of the empyema, but to the severity and long persistence of the underlying and preceding infection. The mortality of acute primary pneumonia in the first two years of life is very high, even in the absence of the complicating empyema—66 per cent. in the first year of life, 50 per cent. in the second.³ We may conclude that those children who present themselves with a quiescent meta-pneumonic empyema have been fortunate in contracting a mild and short-lived pneumonic infection or have a relatively high resistance. In general the acute primary pneumonia of infants has a much longer course than the typical lobar pneumonia of adults and cases of great severity often terminate fatally many weeks after the onset, even when no empyema is present. The age-limits within which we find this high mortality in empyema are precisely those within which we find acute primary pneumonia of infantile type. After the third year lobar pneumonia of adult type replaces the infantile form, and the prognosis at once improves. The pneumonia then has a trifling mortality, and if empyema occurs as a complication it tends to be meta-pneumonic in type. There is little in the study of these cases to suggest that the spread of the infection to parts remote from the lung, to the pericardium, the opposite pleura, the middle ear, the meninges, or the peritoneum is to be attributed to the presence of the empyema or that a more timely or more radical operation might have prevented this extension. There is some tendency to treat these remote infections as complications of the empyema. Thus Goodhart and Still⁴ regard them as emphasising "the importance of free drainage and the danger of delay." It may be that occasionally a collection of pus in the pleura lights up a second time a generalised septicæmic infection, but the accident must be very rare, perhaps as rare as the metastasis to the brain and the formation of a pulmonary cerebral abscess.

Certainly these additional infections, pericarditis, meningitis, otitis media, colitis, nephritis, and peritonitis, are encountered with considerable frequency in fatal cases of primary pneumonia of infancy whether empyema is present or absent.

CASE-NOTES.

1. Operation and Recovery (Thirteen Cases).

CASE 1. *Pneumococcal Empyema, Meta-pneumonic Type.*—Male aged 16 months. Convulsions six weeks before admission. Pneumonia diagnosed. Since then never really well. On admission "septic-looking," with an appearance of general neglect. Temp., normal; resp., 36. Dullness and distant bronchial breathing over whole of right lung; right chest completely opaque to X rays. Heart displaced to left. Aspiration; 22 oz. thick pus withdrawn. Cultivation gave pure growth of pneumococcus. Three days later excision of rib (six weeks after onset of illness). Uninterrupted recovery. Gain in weight in eight weeks after operation 4 lb. 4 oz.

CASE 2. *Empyema, Meta-pneumonic.* Male aged 13 months. Pneumonia five months before admission. Never well since; wasting, shortness of breath, and occasional vomiting. On admission, dullness over right lung, heart displaced one inch to left. Temp., 100° F.; resp., 56; pulse, 156. Resection of rib, half pint of pus evacuated. Rapid recovery. Discharged after five weeks, looking very much better.

CASE 3. *Pneumococcal Empyema, Meta-pneumonic.* Female aged 2 years. Pneumonia three months before admission. Continued ill-health. On admission temp. normal; resp., 36–40; pulse, 130–140. Resection of rib; purulent fluid escaped from right base. Cultivation gave a pure growth of pneumococcus. Rapid recovery.

CASE 4. *Pneumococcal Empyema, Meta-pneumonic Type.*—Female aged 15 months. Pneumonia four weeks before admission. On admission, temp. just above normal; resp., 36; pulse, 130. Needled, pus withdrawn left side. Cultivation, pure growth of pneumococcus. Resection of rib (in fifth week after onset of pneumonia). Recovery after eight weeks in hospital with some irregular pyrexia.

CASE 5. *Empyema, Meta-pneumonic.*—Female aged 15 months. Pneumonia six months previously, since when she had made no progress and had put on no weight. On admission temp. subnormal; resp., 36; weight, 12½ lb. Subcutaneous tissue of left chest (axilla) swollen and oedematous. Tender on percussion. Absolute dullness and bronchial breathing. Needled and pus withdrawn. Cultivation; mixed pneumococcus and *B. influenzae*. Resection of rib in twenty-fourth week after onset of pneumonia. Discharged well eight weeks later. Gained 2 lb.

CASE 6. *Empyema, probably Meta-pneumonic.*—Female aged 21 months. History quite indefinite. Had always had a cough, which became worse three weeks before admission. Wasted child with protuberant abdomen. On admission temp. almost normal; resp., 34–40. Dullness with bronchial breathing at right base. Lobar pneumonia diagnosed. Exploded 13 days after admission, and pus withdrawn. Resection of rib. Immediate improvement. Discharged in good condition 23 weeks later, having gained 3 lb. 2 oz.

CASE 7. *Empyema, Meta-pneumonic.*—Male aged 13 months. History indefinite. Ten days before admission temp. 102°; became better and relapsed again. On admission temp. normal; resp., 40; pulse, 140. Dullness and bronchial breathing over right lung. Two days later explored, clear fluid with "streaks of opaque fluid" withdrawn. Cultivations remained sterile. Rib resection 25 days after admission, purulent fluid evacuated. Cultivations sterile. Rapid improvement and discharged after ten weeks in hospital with great increase in weight.

CASE 8. *Empyema, Meta-pneumonic.*—Male aged 2 years. Brought to surgery for six weeks for obscure illness with vomiting. On admission temp. 99°; pulse, 160; resp., 60. Left side of chest dull. Immediate operation and evacuation of pus; cultivation gave a pure growth of streptococcus. Rapid recovery. Discharged five weeks later.

CASE 9. *Empyema, Meta-pneumonic.*—Male aged 9 months. Brought to surgery for 17 days with obscure illness with cough and vomiting. On admission temp. normal; resp., 36; pulse 140. Left base dull. Heart not displaced. Right lung normal. Left base opaque to X rays. Immediate operation and pus evacuated. Discharged after eight weeks, having gained 3 lb.

CASE 10. *Empyema, Meta-pneumonic.*—Female aged 11 months. History quite indefinite; cough for three months. On admission temperature normal. Left base dull. Explored and pus withdrawn. Resection of rib on day of admission. After two weeks of irregular pyrexia, rapid improvement. First three weeks after operation gained 3 lb. Later developed otitis media and radical mastoid performed. Last five weeks gained a further 3 lb. Discharged after 27 weeks.

CASE 11. *Empyema, Meta-pneumonic.*—Male aged 20 months. Admitted on sixth day of pneumonia, temp. averaging 103°; resp., 60; pulse, 150. Apparent crisis on eleventh day, temperature falling to 100°, respirations to 40, and pulse to 120. Three days later temperature rose to 103°. Whole of right side dull and distant breath sounds. Heart one inch outside nipple line. Explored and pus withdrawn. Resection of rib following day. Temperature immediately fell to normal. Uninterrupted recovery.

CASE 12. *Empyema, Meta-pneumonic.*—Male aged 15 months. Two days' history of high pyrexia and convulsions. On admission breathing rapid, averaging 60; pulse 150–160; temp. persistently above 104°. Crisis on ninth day of illness. Lobar pneumonia (right lower lobe) had been diagnosed. A week later temperature rose again to 102°. On fourteenth day of illness heart displaced to left. Chest explored and 5 oz. turbid fluid withdrawn. Cultivation gave pure growth of pneumococcus. Resection of rib following day. Slow recovery with repeated pyrexial attacks and stationary weight. Discharged after 1 weeks.

CASE 13. *Empyema, Syn-pneumonic*.—Male, aged 21 months. Admitted on fifth day of illness with pain in chest. Temperature remained irregularly high for three weeks, from 102° to 103°; pulse, 168 to 140; respirations from 40 to 60. Dullness and fine crepitations at left base. Heart inside nipple line. Child drowsy. Remaining parts of lungs harsh, dry breath sounds, no râles or rhonchi. Persistent coryza. Three weeks after admission greenish pus withdrawn from left base followed by resection of rib. Irregular pyrexia continued for a week longer; thereafter rapid improvement.

2. Death after Operation (Twenty Cases).

CASE 14. *Empyema, Syn-pneumonic*.—Female aged 13 months. Six weeks before admission, pneumonia diagnosed; three weeks later "fluid in chest." On admission temp., 100°; pulse, 140; resp., 60–70. Edema of skin at right base. Bronchial breathing both bases. Explored on right side and pus withdrawn. Resection of rib same day (in sixth week of illness). Cultivation gave pure growth of pneumococcus. Temp. remained up 100° to 101°, increasing dyspnoea. Died four days after operation. Post mortem: Empyema right side; broncho-pneumonia, bilateral.

CASE 15. *Empyema, Syn-pneumonic*.—Female aged 24 months. Edema of face and legs of sudden onset 14 days previously. On admission temp. 98°; pulse, 130; resp., 40. A week later temp. rose to 102°. Dullness and moist sounds appeared at left base. Empyema diagnosed. Explored and pus obtained. Operation same day (twenty-first day of illness). Temp. remained high; resp. increased. Condition worse. Died 11 days after operation. Post mortem: Pyogenic membrane over left lung; no free pus; pneumonia left side. No pericarditis.

CASE 16. *Empyema, Syn-pneumonic*.—Male aged 1 year. Five days previously shivering convulsions and rapid breathing. On admission temp. 105°; pulse, 160–170; resp., 50. Slight dullness in left axilla. Bronchial breathing and dullness in right axilla. Condition remained unchanged for ten days then complete dullness at left base. Explored, 2 oz. pus withdrawn. Resection of rib under local anaesthesia on twentieth day of illness. No improvement. Death the same day. Post mortem: Bilateral empyema, consolidation and compression of both lungs; bronchial glands inflamed, pneumococcal pericarditis.

CASE 17. *Empyema, Syn-pneumonic*.—Male aged 9 weeks. Cough for one week. No other history. On admission temp. 103°; pulse, 146. Dullness and absent breath sounds base of right lung. Dullness at apex and base of left lung. Explored at right base and pus obtained. Resection of rib on seventh day of illness. No improvement. Temp., 105°; resp., 84. Death the next day. Post mortem: Lower lobe of right lung, and apex and lower lobe of left lung solid with confluent broncho-pneumonia.

CASE 18. *Empyema, Syn-pneumonic*.—Male aged 2 years. A week's history of cough with pain in the chest. Diagnosed as pleurisy with "inflammation of the lung." On admission, temp. averaged 103°; pulse, 160; and resp., 80. No change for 14 days, then subsidence of pyrexia for a week. Temp. rose again, paracentesis on twenty-first day of illness, and pus obtained. Resection of rib on thirtieth day of illness and a small amount of pus evacuated. No improvement, increasing exhaustion and death 12 days after operation, on forty-second day of illness. Post mortem: Left pleura adherent to diaphragm; lower lobe adherent and covered with buttery lymph; no accumulation of pus; 2 oz. turbid fluid in pericardial sac; generalised pericarditis.

CASE 19. *Empyema, Syn-pneumonic*.—Male aged 2 years. History of sudden illness a week previous to admission accompanied by fever, noisy rapid breathing, and delirium. On admission temp., 105°; pulse, 168; resp., 60. Dullness and bronchial breathing over whole of left base. Condition unchanged and continuous pyrexia for six weeks. Left base explored and pus withdrawn. Operation on forty-second day of illness. Death next day. Post mortem: Left lung very small and contracted; extensive broncho-pneumonia on right side.

CASE 20. *Empyema, Syn-pneumonic*.—Female aged 19 months. History indefinite. Cough for a month. On admission irregular pyrexia averaging 104°; pulse, 184; resp., 48. Dullness and râles at left base. Explored and pus obtained. Resection of rib on twenty-third day after admission. Small quantity of thick pus evacuated. No improvement. Death 19 days after operation. Post-mortem report missing.

CASE 21. *Empyema, Syn-pneumonic*.—Male aged 6 months. Admitted on fifth day of illness of doubtful nature but sudden rigidity. Temp., 105° and remained so throughout; pulse, 180; resp., 68. Dullness at right base. Explored and pus obtained. Resection of rib on sixth day of illness and a large quantity of thick pus evacuated. Cultivations gave a mixed growth of *Streptococcus longus* and *Staphylococcus albus*. Drained well, but no improvement. Died four days after operation, on ninth day of illness. Post mortem: Right lung considerably compressed; pleura thickened; patches of broncho-pneumonia.

CASE 22. *Empyema, Syn-pneumonic*.—Male aged 11 months. Feasles six months previously. Fourteen days' history of cough and sleeplessness. On admission temp. 102°; pulse, 36; resp., 56–60. Dullness of left chest. Explored and pus obtained. Resection of rib same day. Cultivation gave a scanty growth of pneumococcus. No improvement. Subnormal temperature and death on twentieth day after operation. Post mortem: Evidence of empyema and broncho-pneumonia; recent lymph over whole of left side; small abscess where tube compressed lung; right lung showed broncho-pneumonia.

CASE 23. *Double Empyema, Syn-pneumonic*.—Male aged 11 months. Admitted on fourth day of sudden obscure illness. Temp., 105°; pulse, 164; resp., 60–80. Dullness of left lung in front and behind. Bronchial breathing in left axilla. Continuous pyrexia. Resection of rib on left side on twenty-second day of illness, and thick pus evacuated. Cultivation gave a pure growth of pneumococcus. Condition became worse. Râles at right base. Resection of rib on right side on the thirty-sixth day of illness. Thick green pus withdrawn. Death the next day. Post mortem: Broncho-pneumonia left lower lobe. Recent pleurisy and adhesions right lower lobe.

CASE 24. *Empyema, Syn-pneumonic*.—Female aged 16 months. History quite indefinite. Treated as an out-patient for a month for bronchitis. On admission continuous irregular pyrexia; pulse, 130; resp., 30. Dullness and bronchial breathing at left base. Condition unchanged. Resection of rib on twenty-fifth day after admission. Small quantity of pus evacuated. No improvement. Death five days later. Post mortem: Pleurisy both sides; no pus; left base consolidated; acute nephritis.

CASE 25. *Empyema, Syn-pneumonic*.—Male aged 6 months. Admitted on third day of illness with sudden onset, feverishness, and cough. Temp., 104°; pulse, 156; resp., 60. Bronchial breathing and râles both sides of chest. Resection of rib on left side on thirteenth day of illness after continuous pyrexia. Death next day. Post mortem: Left lower lobe solid; purulent lymph over left lung; right lower lobe airless.

CASE 26. *Empyema, Syn-pneumonic*.—Female aged 1 year. Admitted to isolation ward on fourth day of measles with cough and dyspnoea. Temp., 103°, and remained high throughout; pulse, 146; resp., 48–60. Bronchial breathing right base. Empyema diagnosed. Resection of rib on twenty-sixth day of illness and pus withdrawn. Direct examination of pus showed pneumococci. Signs of pneumonia now present on left side. Death 24 hours after operation. Post mortem: Both lungs full of broncho-pneumonia; excess of fluid in pericardium.

CASE 27. *Empyema, Syn-pneumonic*.—Male aged 15 months. No history given. Admitted with signs and symptoms of empyema on the left side. Immediate resection of rib and much pus evacuated. Death shortly after operation. Post mortem: Pleura covered with thick purulent exudate; left lung showed some red hepatisation; pyo-pericardium—much pus.

CASE 28. *Empyema, Syn-pneumonic*.—Male aged 2 years. Bronchitis for a month. Two days before admission, short dry cough, vomited, rapid breathing. On admission temp. 103°–104°; pulse, 150; resp., 50–60. Pyrexia remained high throughout. Dullness and crepitations at left base. Needed and pus withdrawn. Resection of rib on fourth day of illness, then foul-smelling pus evacuated. No improvement. Death thirteen days after operation. Cultivation of pus gave pure growth of pneumococcus. Post mortem: Right lung congested; left lung airless, well-marked bronchiectasis; trachea and bronchi congested and full of frothy mucus; bronchial glands enlarged; heart dilated.

CASE 29. *Empyema, Syn-pneumonic*.—Female aged 15 months. History indefinite. Cough and difficulty in breathing for a few days before admission. On admission temp. 104°; pulse, 160; resp., 76. Dullness over the whole of the right side. Immediate rib resection. Became steadily worse and died seven days after operation. Post mortem: Right pleura covered with fibrinous pus; patches of broncho-pneumonia at left base; confluent broncho-pneumonia right lung; some pericarditis.

CASE 30. *Empyema, Syn-pneumonic*.—Female aged 1 year. Three weeks' history of cough and dyspnoea. On admission temp. 99.4°, pulse, 140; resp., 60. Dullness left base. Resection of rib on twenty-third day of illness. Death the same night. Post mortem: Thick fibrinous exudate over left lower lobe, broncho-pneumonia in left upper lobe; some broncho-pneumonia in right lung; heart dilated.

CASE 31. *Empyema, Type Indeterminate*.—Female aged 23 months. History indefinite. One month's illness of doubtful nature. On admission temp. 102°; pulse, 156; resp., 64. Empyema, right side, diagnosed. Heart considerably to left. Resection of rib day after admission. Immediate improvement. Temp., 98.4°; pulse, 138; resp., 40. On twenty-fourth day after operation temp. rose. Condition worse and remained unsatisfactory with irregular pyrexia for three weeks. Death in seventh week after admission. Post mortem: Cavity in right lung opposite operation wound; left lung adherent to chest and airless; pericardium adherent to chest wall.

CASE 32. *Empyema, Type Indeterminate*.—Male aged 14 months. Onset indefinite. On admission temp. 103°; pulse, 150; resp., 60. Dullness at right base. Needed and pus obtained. Resection of rib third day after admission; pus evacuated. Cultivation gave *Staphylococcus aureus*. Some improvement for the next month, but temp. remained irregularly high (104°); pulse about 160; and resp., 56. Death in thirteenth week after operation. Post mortem: Suppurative peritonitis and pericarditis.

CASE 33. *Empyema*. Female aged 7 months. Admitted after about a week's illness with rapid breathing and fever. On admission temp. 105°; pulse, 180; resp., 60. Dullness at right base. Crackling and moist râles all over chest. Explored, thin purulent fluid obtained. Resection of rib on day of admission. Sudden death three hours later. Examination of pus showed many streptococci. Post mortem: Nothing but empyema found; whole of right lung completely airless from compression, and surface covered with a pyogenic membrane; no pneumonia visible on either side; left lung and pleura healthy; dilatation of right side of heart.

3. Death—No Operation (Nineteen Cases).

CASE 34. *Empyema, Syn-pneumonic*.—Male aged 10 months. Admitted to isolation ward 14 days after onset of measles. Cough and wasting since the third day of illness. On admission temp. 104°; pulse, 160; resp., 60. Dullness and bronchial breathing at left base. Temperature remained high throughout. Condition became steadily worse. Death seven days after admission. Post mortem: Localised empyema at left base; pleurisy over right base; extensive broncho-pneumonia of left lung and right lower lobe; recent pericarditis.

CASE 35. *Bilateral Empyema discovered Post Mortem. Syn-pneumonic*.—Female aged 15 months. Bronchitis with pyrexia for three weeks. Night sweats. On admission temp. 102°; pulse, 170; resp., 56. Impaired note all over chest. Sixteen days later physical signs less marked and temperature fell. Opaque to X rays under right clavicle. Confluent broncho-pneumonia diagnosed. Condition became worse. Death eighteenth day after admission. Post mortem: Consolidation of both lungs of lobar type. Bilateral empyema. Recent pericarditis.

CASE 36. *Empyema, Syn-pneumonic*.—Male aged 7 months. Four days' illness of doubtful nature. On admission right side dull to percussion and bronchial breathing. Very dyspnoeic, rapid shallow breathing, high temperature. Lobar pneumonia diagnosed. Death two days later in convulsions. Post mortem: Empyema on right side, 4 oz. pus; extensive pneumonic consolidation of both lungs.

CASE 37. *Empyema, Syn-pneumonic*.—Female aged 15 months. Admitted to isolation ward on fourth day of measles. Otitis media developed, and a week later bronchitis with a very high temp.; pulse, 170; resp., 70. Right side of chest needled on fifteenth day of measles and 4 oz. of turbid fluid removed. Death a few hours later. Post mortem: General pneumococcal peritonitis, broncho-pneumonia and empyema on right side.

CASE 38. *Empyema, Syn-pneumonic*.—Female aged 10 months. A week's history of cough. On admission temp. 102°; pulse, 170; resp., 70-80. Dullness at right base. Explored and pus obtained. Cultivation gave a growth of *Streptococcus longus*. Too ill for operation. Death the next day. Post mortem: Caseous bronchial glands; muco-pus in tubes, pleurisy over right lung; broncho-pneumonia in right lower and middle lobes and also of left lung; empyema right side.

CASE 39. *Empyema, Syn-pneumonic*.—Male aged 8 months. Cough and drowsiness for eight days. On admission temp. 103°; pulse, 140-180, resp., 60-80. Dull both sides of chest, especially right base. Râles all over chest. Diagnosed as broncho-pneumonia. Bronchial breathing at left base on seventh day after admission. Explored 2 oz. pus withdrawn. No improvement. Death 12 days after admission. Cultivation of pus gave *Micrococcus catarrhalis* and *B. influenzae*. Post mortem: Left lower lobe covered with thick buttery adherent lymph; broncho-pneumonia well marked in both right and left lungs; pericarditis; nephritis.

CASE 40. *Empyema, Syn-pneumonic*.—Male aged 6 months. Admitted moribund with broncho-pneumonia. Death same day. Post mortem: Broncho-pneumonia and an abscess cavity in right lung communicating with pleural cavity which contained 2 oz. pus.

CASE 41. *Empyema, Syn-pneumonic*.—Male aged 19 months. History quite indefinite; wasting and ill-health for some months. On admission slight pyrexia; pulse, 168; resp., 40. Dullness at left base. Broncho-pneumonia diagnosed. Both sides of chest explored but no pus obtained (a previous exploration had revealed pus). Death after seven weeks in hospital. Post mortem: Bilateral broncho-pneumonia with 2 oz. pus at right base; acute nephritis.

CASE 42. *Empyema, Syn-pneumonic*.—Male aged 9 months. History indefinite. Admitted with wasting diarrhoea and vomiting. Temp. subnormal. Died on the tenth day after admission with some pyrexia for the last two days. Post mortem: Broncho-pneumonia in both lungs; small empyema at right base.

CASE 43. *Bilateral Empyema, Syn-pneumonic*.—Female aged 15 months. Sudden dyspnoea 12 days before admission; three days later convulsions. On admission temp. 102°; pulse, 150; resp., 50. Great dyspnoea, signs of consolidation at right base, râles and rhonchi all over chest. A week later pulse 168, resp. 60, and continued so for a week. Death on the twenty-eighth day of the illness; pulse, 80; resp., 80. Post mortem: Confluent broncho-pneumonia of both lungs; suppurative meningitis; bilateral empyema.

CASE 44. *Empyema, Syn-pneumonic*.—Male aged 9 months. Indefinite history; cough for a month. On admission temp. 104°; pulse, 156; resp., 60-68. Lobar pneumonia, right upper lobe diagnosed. No operation. Death 13 days after admission. Post mortem: Lobar pneumonia right lobe, pleurisy, and 1 oz. pus at right base.

CASE 45. *Empyema, Syn-pneumonic*.—Male aged 15 months. A week before admission vomited, became feverish, dyspnoea, and diarrhoea. On admission temp. 103°; pulse, 144; resp., 44-56. Signs of lobar pneumonia at right base. Temperature continued high. Sudden collapse and death on twelfth day of illness. Post mortem: Empyema at right base. Purulent pericarditis.

CASE 46. *Bilateral Empyema, Syn-pneumonic*.—Male aged 12 months. Admitted to isolation ward for measles. On admission temp. 103°; pulse, 140-160; resp., 40. Five days later temp. 105°; pulse, 160; resp., 84. Râles all over both lungs. Temp. remained high. Sudden collapse and death 12 days after admission. Post mortem: Small empyema on both sides; extensive broncho-pneumonia; marked colitis.

CASE 47. *Empyema, Syn-pneumonic*.—Female aged 11 months. No history obtainable. Admitted very ill with subnormal temp.; pulse, uncountable; resp., 60. Left chest needled and pus found. Died before operation could be performed. Post mortem: Acute pleurisy right side. Thick, buttery, purulent lymph over whole of left lung. Left lung compressed and showed broncho-pneumonia. Acute pericarditis. Acute colitis.

CASE 48. *Empyema, Syn-pneumonic*.—Male aged 2 years. Two months' history of cough and vomiting. On admission pale, rapid breathing. Temp., 101°-2°; pulse, 180 (?); resp., 80. Marked dullness over whole of right lung, râles, and bronchial breathing. Explored and pus withdrawn. Too ill for operation. Oxygen and strychnine administered. Explored again. Breathing ceased during exploration. Artificial respiration. Death. Post mortem: Right-sided empyema; right lower lobe compressed, pleura thickened; early pleurisy left side; muco-pus squeezed from both bronchi. Bronchial glands enlarged.

CASE 49. *Empyema, Syn-pneumonic*.—Male aged 16 months. In hospital at ten months with broncho-pneumonia. Five days before admission vomited, and breathing became "difficult." On admission temp. 102°; pulse, 150-160; resp., 60. Explored five days later and 10 c.cm. pus withdrawn. Irregular pyrexia. No operation. No improvement. Death seventeenth day of illness. Cultivation of pus, *Streptococcus longus* and pneumococci. No post mortem.

CASE 50. *Bilateral Empyema. Type Indeterminate*.—Male aged 10 months. History very indefinite. Eight weeks ago diarrhoea, recovered. Four weeks ago return of diarrhoea. On admission temp. 102°; pulse, uncountable; resp., 36. Blue lips, semi-comatose. Pyrexia continued. Death seven days after admission. Post mortem: Acute enterocolitis; bilateral empyema.

CASE 51. *Empyema. Type Indeterminate*.—Male aged 6 months. History quite indefinite. Had been dieted for wasting. On admission temp. normal; ten days later temp. 105°; pulse, 150; resp., 56. Bronchial breathing and dullness at right base. Lobar pneumonia diagnosed. Crisis 11 days later. Right base still dull. Explored and pus found. Temp. rose to 103° on twentieth day after crisis, and remained irregularly high throughout. Subcutaneous abscess developed over site of needling. Eight weeks after crisis bronchial breathing at both base. Temperature became higher. Death 13 weeks after admission. No post mortem.

CASE 52. *Empyema. Type Indeterminate*.—Male aged 20 months. Eleven weeks before admission double pneumonia diagnosed. On admission temp., 98.4°; pulse, 144; resp., 40. Dullness and bronchial breathing left apex and right base. Explored third left space 1 oz. pus obtained. Temp. rose slightly. Further exploration without result. Cultivation gave a pure growth of pneumococcus. Decision not to operate. Increasing dyspnoea and death 12 days after admission. Post mortem: Empyema right base, less marked at left base; extensive pleurisy in front; pericardium full of thick green pus, adherent in places; purulent bronchitis; lungs compressed; no broncho-pneumonia.

CONCLUSIONS.

1. The high mortality of empyema in the first two years of life is due to the specific character of acute primary pneumonia of infancy.
2. Meta-pneumonic cases almost always recover. Syn-pneumonic cases almost always die.
3. All meta-pneumonic cases should be dealt with by excision of rib as speedily as possible.
4. Syn-pneumonic cases should not be dealt with by excision of rib until after the termination of the pneumonic process. Some form of paracentesis should be practised as a temporary measure.
5. In syn-pneumonic cases death occurs from the original pneumonia and from metastasis of infection to other parts rather than from the empyema.

DONATIONS AND BEQUESTS.—In response to the special appeal for £15,000 in aid of Ancoats Hospital, Manchester, the donations received up to date amount to £4323. During the past year the Royal Schools for the Deaf, at Old Trafford, Manchester, have received the following legacies: £500 from the late Sir James E. Jones, £200 from the late Miss Elizabeth Hilton, and £1000 from the late Miss Violet Robinson.—The late Mr. John Wall Fothergill, of Southport, bequeathed £10,000 to the National Institute for the Blind, London.—At the annual meeting of the subscribers to the Leigh Infirmary, Lancashire, it was reported that during the year about £6000 had been contributed to its funds and that practically all the collieries and weaving sheds were contributing.—The Manchester Royal Infirmary has received a legacy of £500 from the late Mrs. Ermiah Ingham.

CONGENITAL DEFECT OF THE PECTORALIS MUSCLES.

BY E. B. MORLEY, M.B., B.S. LOND.

CONGENITAL defect of the pectoral muscles, though described in most text-books, is seldom seen. Schlesinger saw five cases in 54,000 patients in Vienna. There are about 220 cases recorded in the literature. R. Bing gives the bibliography up to 1902 and E. Clarke from 1902-1911. Appended to this paper are references to 18 cases recorded since then.

The extent of the deficiency is variable. Complete absence of pectoralis major and minor is rare, the clavicular portion of the pectoralis major being nearly always present to some extent. A case (post mortem) showing complete absence of both muscles—on the left side—without even fascial bands to represent them, was described in THE LANCET by A. G. Severn during 1921.¹⁸ Only one case has been noted where the defect was bilateral. Absence of the pectoralis minor unassociated with defect of the pectoralis major does not occur; the defect is usually greater below than above; and this is important when the embryological aspect is considered. The influence of heredity is uncertain, for though Clarke quotes only one instance (where a father and two sons were affected) it is not uncommon to find—as in two of my cases—some members of the family with congenital defects of other structures.

Possible Causes of Pectoral Defect.

1. In some animals the pectoral group of muscles is complex. Thus, Lander describes six pectoral muscles in *Trichosurus vulpecula*. So also in man, definite grouping of fibres of pectoral muscles does occur, and it has been suggested that congenital deficiencies may be explained along the lines of phylogenetic retrogression.

2. Pressure of forearm or of knee of foetus in utero causing atrophy and fibrosis of developing muscle plates—a sort of ischæmic contraction. In favour of

FIG. 1.

CASE 1.—Whole of right pectoralis major and minor absent except for a thin slip.

his is the fact that portions of the muscles have been found represented by a fibrous cord extending from the chest to the humerus.

3. Absence of external and internal anterior thoracic nerves. This rather begs the question. One would not be likely to find a nerve present without its corresponding muscle to innervate.

4. The explanation that falls in with most of the facts is that of Lewis. He points out that in the 1 mm. embryo, the primitive pectoral premuscle mass is mostly above the level of the first rib. In the 1 mm. embryo it extends lower, but has no attachment to ribs or to humerus. It is still undifferentiated into its component parts, except that the pectoralis minor is indicated by a bulge towards the coracoid. In the 16 mm. embryo the clavicular portion is split off, and then the remainder divides into the sternal portion and the pectoralis minor.

Here, then, is a possible explanation of the fact that the clavicular portion is seldom absent; the pectoral anlage has been formed, but has not become differentiated. It also suggests a reason for the fact that the defect is always greatest towards the caudal end. The muscle mass has a cervical origin and has failed to migrate caudally to an extent sufficient for attachment to ribs and sternum to take place.

Eight Actual Cases.

Since 1913 I have come across eight cases of pectoral defect. The first case was seen in a private

FIG. 2.

CASE 7.—Clavicular portion of pectoralis major, and part of sternal portion attached to manubrium and second rib, well developed. Remainder of pectoralis major and whole of pectoralis minor absent.

patient, and the remainder in recruits for the army. The photographs of Cases 1, 7, and 8 indicate three different degrees of defect.

CASE 1.—Male, aged 13, seen in 1913. (See Fig. 1.) Defect discovered in routine examination for a cough. A healthy boy; no abnormality noticed by his mother. Except for a thin slip from the clavicle, the whole of the right pectoralis major and minor are absent. This produces an enormous cavern in the right axilla, and is most noticeable when the arms are raised and pressed firmly towards each other on some fixed object. The nipple is neither absent nor displaced upwards, as in some of the cases described in the literature. The boy's father has a supernumerary toe on the right foot, and a niece of the father had supernumerary right and left thumbs.

CASE 2.—Male, aged 34, seen Feb. 9th, 1917. Collier, recruit. Except for a small clavicular portion, the remainder of the pectoralis major and the whole of the pectoralis minor are absent on the right side. Nipple normal in size and position. The recruit had never noticed any disability, but said he had been rejected previously for the army, because (he was told) he had a "fibrous" lung. On examination no signs were found in the chest. The man's sister had a cleft palate.

CASE 3.—Male aged 24. Seen Feb. 9th, 1917, the same day as Case 2, but no relationship could be traced. Collier, recruit. Clavicular portion of pectoralis major present. Sternal portion and pectoralis minor absent on the right side. Nipple normal in size and position. No brothers or sisters. Parents said to be normal.

CASE 4.—Male aged 31, seen May 14th, 1917. Potter, recruit. Except for the usual clavicular portion, pectoralis major and minor on left side absent. Nipple normal in size and position. No history of abnormalities in other members of family.

CASE 5.—Male, aged 32. Seen May 30th, 1917. Railway clerk, recruit. In this case the only portion missing was the lower half of the sternal portion of the pectoralis major below the third rib on the left side, and but for the fact that I had seen previous cases would certainly have escaped notice.

CASE 6.—Male, seen June 22nd, 1917. Recruit. Exactly the same as Case 5, except that the missing lower portion of pectoralis major is on the right side. Nipple present. No family history of deformities.

CASE 7.—Male, aged 19, seen Sept. 22nd, 1920. Recruit. (Fig. 2.) Defect on right side. Clavicular portion of pectoralis major, and that part of the sternal portion which is attached to manubrium and second rib, present and well developed. The remainder, and pectoralis minor, absent. Nipple normal in size and position. The recruit made inquiries, but could find no similar condition in other members of the family.

CASE 8.—Male, aged 20, seen December, 1921. Soldier. (Fig. 3.) Defect first noticed at age of 14 during an attack of pneumonia. On right side sternocostal fibres from second to third ribs present, but feebly developed. On left side, pars clavicularis is well developed, but, except for a small slip from the third rib, remainder of pectoralis major and whole of pectoralis minor absent. No alteration in size or position of nipple. No family history of deformities.

Summary.

Eight cases of defect of the pectoral muscles are described, all in healthy males, showing four different

FIG. 3.

CASE 8.—Sterno-costal fibres from second to third rib feebly developed; except for small slip from third rib, remainder of pectoralis major and whole of pectoralis minor absent.]

degrees of defect. In no case was the patient aware of the condition and no lack of muscular power could be discovered. In no case was the nipple absent or displaced. In all cases some representative of the pectoral anlage was present, even if only a small clavicular slip. In Case 8 there was some degree of bilateral defect; in the remainder, five were on the right, two on the left. In two cases totally different types of congenital abnormality were found in other members of the family.

The fact that five of the cases were seen in the short period of five months suggests that the condition is much commoner than imagined, and that the lesser degrees of defect are only likely to be noticed if other cases have already been seen.

In cases seen post mortem, it would be interesting to note the presence of compensatory hypertrophy in other muscles, any alteration in the bony structure of the shoulder girdle and changes in the disposition of coraco-humeral ligaments and fascial planes. Congenital defect of the pectoral muscles follows a definite line of distribution, greater below than above, and probably reproduces various stages of foetal development, as do the various degrees of cleft palate.

Mill Hill, N.W.

THE EXPERIMENTAL PRODUCTION OF A FATAL NEPHRITIS

WITH A FILTER-PASSING VIRUS OF NERVOUS ORIGIN.

By C. C. TWORT, M.D. ABERD.,

ROSE RESEARCH FELLOW, ST. BARTHOLOMEW'S HOSPITAL;

AND

H. E. ARCHER, M.R.C.S. ENG.,

DEMONSTRATOR OF CHEMICAL PATHOLOGY, ST. BARTHOLOMEW'S HOSPITAL.

THE question of the ætiology of many cases of nephritis in man remains obscure, and in view of the importance of the disease and the frequency with which conditions associated with urea retention lead to death, any observations which will help to elucidate the matter naturally claim one's attention. In this paper it is not proposed to consider nephritis caused by known animal and vegetable parasites or their toxins, poisons, &c.; the discussion will be confined to that occurring as a complication or sequelæ of filter-passing virus diseases, as well as with those cases of acute and chronic Bright's disease whose causal agent is unknown. By the intracerebral inoculation of a filter-passing virus obtained from nervous tissue we have been able to produce a fatal nephritis, uncomplicated by the presence of bacteria.

Nephritis following on an attack of scarlet fever is a variety of kidney inflammation which is of great interest, for there is the question as to whether the specific filter-passing virus or the accompanying streptococcus is the primary ætiological factor. Although the latter parasite may be seen and isolated from the throat, blood, kidneys, &c., of a large proportion of cases, the chief histological features of the nephritis are usually not those of the reaction against an ordinary bacterium, but rather against that of a filter-passing virus. In some cases the streptococcus cannot be recovered, and, on the other hand, streptococcal septicæmias very often produce no nephritis at all, although neither of these objections rules out the possibility of the streptococcus being the primary factor in the disease. The tissue reactions form an important guide in this, as in so many other conditions, where one is searching for the cause of an unknown morbid process.

Nephritis in Veterinary Pathology.

It seems that frequently insufficient consideration is given to this side of the question by investigators, and far too many parasites have been designated as the causal agent of diseases which, on the face of the histological findings, are extremely unlikely to play any more than a secondary part in the disease in question. Several instances might be mentioned in human pathology, but it is especially in the veterinary field that one meets with so many examples of injudicious and unconvincing publications where an ordinary vegetable parasite is given as the active agent when the clinical and histological features are obviously those of a filter-passing virus disease. In veterinary pathology nephritis is frequently recognised as a complication of diseases due to filter-passers—distemper of dogs, swine fever, foot-and-mouth disease, &c.; while in medical pathology it is associated with scarlet fever and more rarely with measles. Also, the condition known as trench nephritis is usually thought to be caused by a filter-passers. It is not, as a rule, considered that German measles, varicella, &c., as well as many other filter-passers diseases, are followed by renal inflammation: on the other hand, the ætiology of a large number of cases of acute and chronic Bright's disease remains obscure. Metchnikoff's theory of the absorption of intestinal toxins would appear to be a highly feasible explanation, although it is probable that filter-passing viruses may play a much more important part than is generally recognised. Our experiments on

encephalo-myelitis and nephritis of rabbits would appear to be of some interest in this connexion.

Observations in Animals.

The earliest observations of lesions of encephalitis in normal rabbits are, as far as we are aware, those of Bull.¹ This author was experimenting with injections of streptococci, and found in his animals a mononucleosis of the central nervous system. Similar lesions were found in one of three rabbits which had succumbed to a bacillary septicæmia. Later, Oliver² described a similar condition in her rabbits which had been subjected to repeated large doses of arsphenamin, over a period of ten days; such animals dying, as a rule, from the effects of this procedure. However, experimental rabbits which died in a few days following the injection of the same drug showed similar lesions of the central nervous system, and thus led her to examine the supposedly normal animals of her stock as well as a number obtained from the public markets. In both instances about 20 per cent. of the animals showed lesions of encephalitis.

A Spontaneous Outbreak among Stock.

We had not encountered the disease previous to the winter of 1921-22, when an outbreak occurred spontaneously in our stock. During the course of some experiments on lymphadenoma and allied diseases several of our animals succumbed in a rather unexpected manner, and post-mortem examinations failed to reveal any obvious lesions in the thoracic or abdominal viscera. Histologically, however, lesions characteristic of those associated with the presence of a filter-passing virus were demonstrable in the central nervous system and in several of the other organs.

At the time of the publication of our first communication on the disease,³ we were unaware of the observations made previously by Bull and Oliver, and there is no doubt that the disease prevailing in America is the same as that occurring in this country. It is curious that while in our stock, in the original epidemic, death occurred in practically every case in which symptoms were evident, the animals of these authors were mostly in good health until a fatal experimental dose of arsphenamin or streptococci was given; and subsequent examination of the central nervous system revealed the unexpected round-celled infiltration of an encephalitis. We are unable to gather from Oliver's paper exactly how her animals reacted to the disease clinically; she mentions in one place that they "rarely die," but it appears that, generally speaking, health was normal previous to the utilisation of the animals for experimental purposes.

Subsequent Observations: Absence of Nervous Symptoms and Many Recoveries.

Although in our original epidemic symptoms of the disease indicated practically a fatal prognosis, subsequent observations have shown that many rabbits may have lesions of the central nervous system without any apparent disturbance of their health. Some may show slight symptoms, and others even a rather severe indisposition, and eventually make an apparently perfect recovery. Among our stock we can never be certain that an animal is not suffering from the latent disease which may at any time lead to a rapidly fatal termination. Outside these laboratories we have, up to the present, not met with the spontaneous disease, and the normal animals examined have had no histological changes in the central nervous system. It was very soon noted that the extent of the lesions of the central nervous system did not follow closely the severity of the symptoms. Among the first 16 fatal cases, on several occasions, only insignificant changes could be demonstrated, while in other animals a very intensive round-celled invasion was observed, extending the whole length of the central nervous system, although much more marked in the brain than in the cord. The cells were

scattered or agglomerated into foci, or surrounded the vessels in the typical manner. Chromatolysis and neuronophagy were also sometimes present, together with an invasion of the meninges. The cerebro-spinal fluid varied from normal to a well-marked mononucleosis, but cultures of the fluid, as also those of the blood, remained invariably sterile, with the exception of an occasional accidental contaminating colony.

In view of the absence of nervous symptoms, with often an extremely slight degree of microscopical evidence of disease of the nervous system, and that histological examination of the kidneys revealed considerable damage to the organs, together with less extensive changes in the liver and spleen, it was evident that possibly we were dealing frequently with cases of renal death and not with death of a nervous origin, although, undoubtedly, some of our cases had died from the changes in the nervous system. Thus, in our later animals, not only was a more careful microscopical examination of the kidneys and urine carried out, but biological tests of renal function on the blood and urine were performed whenever possible. The results obtained were most conclusive evidence of death occurring, in the majority of cases, with urea retention.

Ætiology of Spontaneous Nephritis of Rabbits.

Spontaneous nephritis of rabbits has long been recognised, and numerous workers have come across the disease while studying the experimental production of nephritis in this variety of animal. From the examinations made by Bell and Hurtzwell,⁴ and by the several authors they mention, it appears that among 400 animals, the kidneys of about 15 per cent. show evidence of renal disease. It is only recently that we have encountered the spontaneous nephritis, which has been usually accompanied by lesions of encephalitis. According to Bell and Hurtzwell, "we are not dealing . . . with a diffuse interstitial nephritis such as occurs in diphtheria and scarlet fever, but with discrete foci which cause atrophy of the entire tubule system by destroying its central portion." This describes very well the appearance of the kidneys of animals which remain more or less active and healthy, but in the case of death with urea retention it is not always a question of discrete foci, which, although present, may not dominate the picture. A glomerular nephritis is sometimes met with, but still more frequently it is the convoluted tubules which suffer most severely, and the lining cells of which may be so destroyed that only an occasional normal portion of this part of the tubule can be seen. It is unfortunate that in the publications on spontaneous nephritis of rabbits which we have perused we have found no evidence of the examination of the central nervous system made in conjunction with those of the kidney, and Oliver does not mention specifically whether the kidneys were examined in her cases of spontaneous meningo-encephalitis.

Bell and Hurtzwell contend that in all probability the virulent staphylococcus which was isolated on two occasions from their cases of spontaneous nephritis was the causal agent of the disease, an opinion with which we cannot agree, although the said staphylococci were isolated in pure culture. It seems more probable that the staphylococcus was associated with a specific filter-passing virus, as a secondary infection, examples of such an association being frequently found in diseases of man and animals. The fact of there being primarily a mononuclear invasion and not a polynuclear one should make one hesitate to assign an ordinary bacterium as causal agent of the disease, although, of course, some special bacteria, such as members of the acid-fast group and a few other related forms, do excite the migration of lymphocytes. An invasion of lymphocytes under the sole stimulus of an ordinary bacterium would appear to occur with a frequency about equal to that of a polynuclear invasion excited by a filter-passing virus;

that is to say, at the most it is very exceptional, and probably really does not occur at all.

Urea Content of the Blood.

The estimation of the urea content of the blood was carried out by means of a micro-method adapted to the small amounts of blood available, the technique being, briefly, as follows: 0.2 c.cm. of blood was incubated at 50° C., with 1 c.cm. of water, and 0.2 c.cm. of a 10 per cent. solution of urease, ammonia developed by the enzyme action being fixed by the acid phosphate present in the urease solution. The proteins were precipitated by adding 0.3 c.cm. of a 10 per cent. solution of sodium tungstate and 0.3 c.cm. of 2/3 normal sulphuric acid, the solution diluted to 8 c.cm. and filtered. 5 c.cm. of this filtrate (representing 0.125 c.cm. of blood), diluted with 5 c.cm. of water, were treated with 2 c.cm. of Nessler reagent, and the resulting brown colour compared with that obtained by nesslerising a standard solution of ammonia; the standard ammonia solution being of such a strength that 1 c.cm. was equivalent to 0.0001 g. of urea. The comparisons were made in a Kolber colorimeter. The method has been previously tested upon a large number of human blood specimens and control urea solutions. The results of these tests, which are the subject of another paper,⁶ have convinced us of the accuracy and usefulness of the method.

Single Causative Agent of Spontaneous Forms of Nephritis and Encephalomyelitis.

As mentioned in one of our previous communications,⁶ we arrived at the conclusion that the spontaneous nephritis and the spontaneous encephalomyelitis of rabbits were probably caused by a single virus, and experiments which we have carried out in this direction certainly support our view. The most conclusive experiments with reference to this question were performed on animals at the Brown Institution. Neither of the conditions had been observed among the stock of this institution, but just prior to the commencement of our experiment we took the precaution to make a careful examination of six normal animals, selected haphazard, and we were unable to find any histological changes in the organs.

Two litters of four young and their mother were taken for the experiment and removed to another stock room, situated in an entirely separate building. The four young of one litter were injected intracerebrally on July 12th, 1922, with a small quantity of an emulsion of spinal cord, preserved in 50 per cent. glycerine in saline, in cold storage, for six months, of a rabbit which had died from spontaneous encephalomyelitis. The mother was left with her young and served as a control, while the second litter of four young and their mother were placed in an adjacent cage, a few cubic centimetres of the glycerinated emulsion being sprayed on the bedding in the bottom of the cage. For several months all the animals seemed quite healthy, but it was noticeable that those which had received an intracerebral injection did not grow into such robust animals as those of the second litter. It will be unnecessary to go into detail as regards the subsequent history of these animals. It will suffice to say that the four inoculated animals died at intervals varying from three to four and a half months after injection, and their mother died five months after this date. The other litter and their mother are still living and apparently in perfect health. The duration of acute illness varied from one to two days. The animals at death were thin, and a certain amount of coccidial disease of the liver was present in three of them. But this, evidently, was not the cause of the death, as there was an absence of diarrhoea, purulent secretion from the eyes, &c., which one usually associates with death from this variety of animal parasite; and in the mother and remaining young there was no trace of coccidial disease. As a matter of fact, coccidiosis has been endemic among the stock of the

Brown Institution for years, but the central nervous system and kidneys of the animals which died never showed changes comparable to those with which we are at present concerned here.

Histological Findings.

The histological findings in the animals now under consideration were very illuminating; the typical lesions of encephalitis and a slight degree of meningitis were found, but the most interesting feature was the presence of nephritis of varying intensity. The blood-urea concentration was very high—viz., 0.4 to 0.53 per cent.—with the urine, in those cases where obtainable, showing a correspondingly low figure. The normal figure of rabbits, guinea-pigs, cats, and dogs we have found to vary from 0.025 to 0.05 per cent., being about the same as that found in man. Thus, there appears to be no doubt that by the inoculation of a filter-passing virus into the brain of these four animals one produced a fatal inflammation of the kidneys, and death with urea retention. True, it may be objected that our inoculum consisted of a brain emulsion and not of a filtrate; on the other hand, cultures of the blood, cerebro-spinal fluid, &c., have remained uniformly sterile, and the histological findings are characteristic of those found associated with the presence of a filter-passing virus. Needless to say, experiments with Berkefeld filtrates, similar to those under discussion, are being undertaken, so as to exclude, as far as possible, the action of an ordinary vegetable parasite. We say as far as possible, because numerous experiments with porcelain filters have shown us how, under certain circumstances, bacteria may pass such filters, even those of a much finer texture than the Berkefeld. Experiments with the heated virus will, in addition, be performed.

Established Presence of Filter-passing Virus.

We consider, then, that there is no reasonable room for doubt that the animals in question died from the presence of a filter-passing virus in the kidneys, the virus being the sole agent in the production of the nephritis, and unassociated with any ordinary vegetable parasite. Our results are in accordance with those of Condrea,⁷ who has reported the production of an experimental nephritis in rabbits as the result of the intracerebral injection of vaccinia virus, and we are under the impression that nephritis has also been produced in rabbits experimentally with encephalitis-lethargica material. One assumes that these investigators took the precaution to exclude the presence of spontaneous nephritis among their stock. It will be noted that the uninoculated mother succumbed soon after the death of her four inoculated young—a clear case of cage infection. On the other hand, the second litter of the mother and four young remain healthy, although material which was proved by injection to contain virus was scattered over the bedding. This is an example of what one finds frequently when experimenting with related viruses, such as that of distemper of dogs, &c.—viz., cage infection from animal to animal, but not from fomites to animal—when one is using the homologous virus. The case is different with a heterologous virus; thus while it is comparatively easy to infect, by experimental inoculation, some varieties of animals with the virus of human encephalitis-lethargica or infantile paralysis, it is rarely that one meets with cage infection.

Four rabbits which had been extensively inoculated on the skin of the back with vaccinia virus, and after showing a typical eruption, made, apparently, a complete recovery, were given to us by the kindness of Dr. M. H. Gordon. Of these animals, one was very ill just before being anaesthetised, the remaining three being quite healthy. The blood-urea concentration of the animal which was ill was 0.6 per cent., the highest figure we have obtained in man or animal; that of the three other animals was normal in amount. Presumably, this animal suffered from spontaneous nephritis, for it had only been inoculated with vaccine ten days prior to death, and it is unlikely that the

latter virus would have destroyed the kidneys so rapidly.

It is only occasionally that we have been able to detect a rising blood urea figure in animals some time prior to their death. It is usual for it to keep normal even when the animals are getting thin, and are obviously ill, and the suddenness with which death occurs is often most unexpected. A complete examination of the urine has not been possible, as we have no special cages for the collection of the urine. As far as we have been able to investigate isolated specimens, the urea concentration of the urine has been found to be low when the blood urea figure was high, and albumin is usually present. Other pathological and normal chemical constituents of the urine have not been estimated. The urine is usually turbid with granular casts and renal epithelial cells, but although an abundance of well-formed tubule cells indicates an acute inflammation, we have on no occasion observed the presence of red blood cells. It is to be regretted that sugar estimations of the blood and urine were not made, for in several cases the symptoms, taken as a whole, were very suggestive of glycosuria.

Clinical Symptoms of the Spontaneous Disease.

The clinical features of the spontaneous disease are not very striking; indeed, on occasions, the course is so rapid that from the onset of symptoms to death there is a lapse of time of less than 24 hours. The onset is usually insidious, and the first indication of any trouble is, in most cases, wasting of the animal. The temperature is, at times, markedly subnormal; 97.4° and 97.7° F. in two cases; among a very large number of temperature observations on this variety of animal, normal and diseased, we have never recorded such low figures unless death was imminent. A frequent feature is the patchy shedding of the hair, which may occur in several situations, the most usual being at the back of the neck and along the spines as far back as the mid-lumbar region. Discharge from the eyes, without much inflammation, may also occur, but in rabbits this condition is met with in several other diseases, and is thus not of much value from a diagnostic point of view. It is, however, as a rule, unaccompanied by diarrhoea. Respiration is normal, and there is a complete absence of any analytic phenomena. There may be considerable nœmia, with a high colour-index and the presence of numerous erythroblasts, a condition of the blood which we have found associated with distemper of dogs. As the disease progresses, emaciation becomes profound, although the appetite seems to be fairly good; and for a considerable time the animal keeps bright and active in spite of general muscular weakness. In no case have we observed œdema of the subcutaneous tissues. Convulsions may occur as a terminal phenomenon, and in two cases the tongue has been severely bitten, presumably during a convulsion. During the whole course of the disease there remains nothing to indicate implication of the nervous system. Death takes place during a convulsion, which may or may not have been preceded by a short period of coma, or it may take place in coma. The length of time for which an animal may survive after the first symptoms have been noted has varied from 15 hours to several days.

It appears that complete recovery may occasionally take place after the advent of symptoms, favourable signs being a rise of temperature, an increase in weight, and renewal of hair. With the experimental disease recovery is more frequent, and a good number of our animals have shown no evidence at all of any effect of the inoculation. The majority of the animals which harbour the virus naturally keep in apparently perfect health, but once symptoms occur in such animals, fatal termination, in our experience, almost invariably resulted.

Post-Mortem Observations.

Among our rabbits we have had in all 36 deaths in which no evident cause of death was observed on

post-mortem examination. Of these 36 animals, the central nervous system was examined histologically on 34 occasions, and the kidneys on 22 occasions. Lesions were found in the former situation 28 times, and in the latter situation 22 times. The cerebro-spinal fluid was examined in 26 cases, a mononucleosis being found on 11 occasions. The urea concentration of the blood was tested in 19 cases, and found to range from 0.2 per cent. to 0.6 per cent. on 16 occasions. In no case has there been both a mononucleosis of the cerebro-spinal fluid, and a high blood urea; and it is probable that in our early cases, when the cerebro-spinal fluid was normal with but slight lesions in the nervous system, and in which the blood was not examined for urea, death was really due to the renal lesions, with urea retention. We consider, therefore, that among our animals death of a renal origin was really over twice as frequent as death of a nervous origin. Besides the above-mentioned 36 animals, we have killed 20 controls, all of which were apparently in good health although several of them had been inoculated with different filter-passing viruses. Lesions were found in the central nervous system and kidneys on several occasions, but in no case was there a mononucleosis of the cerebro-spinal fluid, nor was there any abnormality in the urea concentration of the blood or urine.

The table given below shows our results in fractions, the numerator denoting the number of times in which positive results were obtained, and the denominator the number of examinations made. A positive result in the case of the central nervous system implies a round-celled infiltration, in the cerebro-spinal fluid a similar infiltration, in the case of the kidneys the presence of a well-marked nephritis, and in the blood a urea concentration of at least 0.2 to 0.6 per cent.

Variations of Lipase Content of Blood.

In view of the nature of the virus concerned in this disease of rabbits it was thought probable that variations in the lipase content of the blood would be found to exist in different stages of the disease, and this idea was not difficult to confirm by experiment. Variations are found in diseases due to acid-fast bacilli, and would presumably be also evident in those caused by animal parasites, but one would expect to find the most marked changes in the case of filter-passing virus diseases owing to the process being, as a rule, more acute, and the degree of immunity in recovered cases being very high. The associated mononuclear activity in the above-mentioned group of diseases must evidently be closely related to the amount of lipase present, and it would seem that the secretion of lipase is possibly in the nature of an immune reaction.

Our first procedure in this direction was conducted with a view to the ascertaining of the lipase content of the blood in normal man and animals. The majority of the bloods tested came from man, rabbits, and guinea-pigs, but we were also able to procure several post-mortem specimens from cats and dogs which had been destroyed on account of old age, mange, &c. The normal figures we obtained were as follows; that of some being, of course, well known previously, and our results confirming those of other workers. Over 200 of these tests have been performed.

The figures relate to the amount of decinormal soda solution, measured in cubic centimetres, required to

neutralise the acidity produced by the fermentative action of the lipase in 1 c.cm. of serum on 0.26 c.cm. of ethyl butyrate, after incubation at 37° C. for 24 hours; thymol blue being used as indicator.

Human sera	about 0.25
Rabbits' sera	" 0.37
Guinea-pigs' sera	" 1.20
Dogs' sera	" 0.30
Cats' sera	" 0.40

The remarkably high figure of the guinea-pig is interesting, and certain authors associate the high lipase with the high complement titre of the serum in this animal. We were unable to confirm this opinion, and found no strict parallel between the amount of lipase and the amount of complement present. Also, dialysing and heating experiments did not act in the same manner on the two substances, although we found that heated lipase was partially re-activated by the addition of a small quantity of complement, due allowance being made for the fresh lipase added with the complement. Post-mortem blood we have found to be unreliable, unless taken soon after death or unless the serum can be obtained where it has separated out free from the corpuscles. A certain amount of hæmoglobin does not interfere with the test except for the fact that it renders the reading of the end-point rather more difficult than when clear. Sera can be kept for months without a diminution in the lipase titre, and, as a matter of fact, it appears to be rather raised than lowered, especially with rabbit's serum.

During the acute stages of a filter-passer disease we anticipated a fall in the lipase content of the blood and a substantial rise later on, in the event of the patient making complete recovery. We have not been able to demonstrate with certainty any appreciable fall during the course of such diseases, but the rise in rabbits, when immunity has developed, was marked. A rise of more than double the normal figure has been found in several rabbits which had recovered from severe symptoms of encephalo-myelitis, and in four rabbits 10 to 14 days after inoculation on the skin with vaccinia virus. We have come to no conclusion as regards the length of time for which the lipase titre remains elevated, but probably it is not comparable to that of the immunity. So far, tests on the post-mortem blood of several dogs suffering during life from distemper have yielded nothing of note, but samples of blood from dogs which had recently recovered from the disease have, unfortunately, not been available.

Other Conditions Probably Caused by a Filter-Passing Virus.

For some time we have been carrying out experiments on lymphadenoma and allied diseases of man, and the more we studied this group of diseases the more did it appear to us possible that a filter-passing virus might be the primary aetiological factor. The reasons which led us to this conclusion cannot be discussed here, although it may be mentioned that in addition to the experimental anæmias which we have produced by the injection of a filter-passing virus, such diseases as leukæmia of fowls,⁸ pernicious anæmia of horses,⁹ &c., are known to be caused by this category of virus. As was expected, we found in lymphadenoma, myelocytic and lymphatic leukæmias, and pernicious anæmia an undoubted lowering in the lipase content of the blood. In a case of lymphadenoma the serum was once completely devoid of lipase, but the titre in this group of diseases usually ranged from about 0.1 to 0.15. Glycerinated extracts of liver, spleen, and lymphatic glands, obtained post mortem from blood disease cases, were also compared with extracts of normal organs; the results have not proved to be of much interest, although, up to the present, only a small number of tests have been performed. We were not surprised to find that the glycerine extracts of liver gave a high figure—viz., from 2 to 3; extracts of spleen and lymphatic glands being, relatively, poor in lipase. The glycerine extracts remain unaltered for a great length of time if stored in the cold.

Summary.

1. Spontaneous encephalo-myelitis and spontaneous nephritis of rabbits are caused by a single virus; almost certainly a filter-passer.
2. Death in these cases may be of either nervous or renal origin, although usually of renal origin.
3. In the former case nervous lesions predominate in the cerebral cortex and the mesencephalon, and there is usually a demonstrable mononucleosis of the cerebro-spinal fluid. There are no symptoms indicating disease of the nervous system.
4. In the latter case renal lesions predominate, but although there is an abundant desquamation of tubule cells, and passing of casts, hæmorrhage is absent. The blood-urea concentration is very high, while that of the urine is correspondingly low. Albumin is present in the urine. A remarkable feature is that there is no oedema of the subcutaneous tissues. The profound wasting in some cases suggests the possibility of a glycosuria, but tests for sugar were, unfortunately, omitted.
5. With the advent of symptoms, death in the spontaneous disease is almost invariably the rule; in the experimentally produced disease recovery is not infrequent.
6. Natural or cage infection is frequent, especially among young animals. Artificial inoculation often fails to lead to any symptoms, due possibly to a previous mild attack having produced a certain degree of immunity.

General Conclusions.

1. A fatal nephritis may result from the action of a filter-passing virus in the absence of any other variety of parasite.
2. Such a virus may cause death with urea retention, although the virus was obtained from diseased nervous tissue, and although the portal of entry was by the central nervous system.
3. Cage infection from animal to animal when the disease concerned is that from which the animal naturally suffers is frequent, but this is not so in the case of fomites to animal, nor is it so when a heterologous virus is used, although the animal may be susceptible to artificial inoculation of such a heterologous virus.
4. When an immunity to a filter-passer disease has become established the lipase content of the blood may be considerably increased; in many other diseases which excite a mononuclear activity, including blood diseases of doubtful aetiology, there is a lowering of the lipase content of the blood during the active stage of the disease.
5. Glycerine extracts of normal liver contain about ten times the quantity of lipase as compared with that of the blood serum or that of glycerine extracts of spleen or lymphatic glands.

MEMORIAL TO LIEUT.-COLONEL EDWARD MANSEL-SYMPSON, M.D.—On May 20th, at a special service at St. Mary Magdalene's Church, Lincoln, two stained-glass windows, in memory of Edward Mansel-Sympson, were unveiled. The glass in the western window has been designed in allusion to Colonel Mansel-Sympson's professional career. The left-hand light embodies the figure of St. Luke, with pen and book, and the right-hand one the figure of St. Bartholomew, holding a knife, the instrument of his martyrdom. In a small pane above the lights is the staff of Æsculapius. The eastern window commemorates his antiquarian and literary interests.

Clinical and Laboratory Notes.

A CASE OF CEREBRAL ABSCESS IN A CHILD.

BY J. PORTER PARKINSON, M.D., F.R.C.P. LOND.,
SENIOR PHYSICIAN AT THE QUEEN'S HOSPITAL FOR
CHILDREN, LONDON, E.;

AND

L. R. BROSTER, M.Ch. Oxf., F.R.C.S. Eng.,
ASSISTANT SURGEON AT THE QUEEN'S HOSPITAL FOR CHILDREN.

The following case is worthy of record for reasons given below:—

A girl, aged 4 years, was admitted under the care of one of us (J. P. P.) to the Queen's Hospital for Children on Feb. 24th, 1922. She was the last child of a healthy family of seven. The mother was healthy, but the father has paralysis of the legs and is losing his sight.

History.—The patient had measles 18 months previously, was stated to have had broncho-pneumonia 12 times, and had been ill since the last attack four months before. A month previous to admission she had a fit, followed by a second a few days later; a third occurred two days before admission and one on the day of admission. In these fits the left arm began with clonic contractions, then the leg and head twitched; this lasted about half an hour during which time consciousness was retained. After the fit the child complained of headache and said the left arm was weak. The nutrition of the muscles was normal, as also were the reflexes, except for an extensor plantar reflex on the left side. Bronchitic sounds were heard over both lungs, being much more numerous over the right lung. The heart and abdominal viscera appeared normal. There was no fever except for a slight rise early in March. The Wassermann reaction was negative.

Course of Case.—During the two months she was in hospital the patient had three more fits; on April 5th she was sent

Photograph of the child's brain, showing cavities of cerebral abscesses.

to the seaside branch hospital at Bexhill, being sent back on June 21st. Then a tender, fluctuating swelling was found in the right parietal bone, about half the size of a walnut. The fits recurred more frequently, and were Jacksonian in type, always commencing in the right arm; gait was unsteady and left leg weaker than right; knee-jerks could not be obtained, and abdominal reflexes were absent. Pupils were dilated and equal, and reacted to light and accommodation. There was well-marked optic neuritis. Lumbar puncture gave a clear fluid under slight pressure, normal on chemical and microscopic examination. There were occasional attacks of vomiting and complaints of headache. The lump on the head was aspirated, and a greenish pus evacuated, containing *Staphylococcus aureus*.

Operation.—On July 12th the skull was trephined. A large crescentic flap was turned down from the right frontoparietal bone; the top of its curve reached the mid-line of the skull, where there was a small abscess which had previously been opened. On exploring the bone a minute sinus, lying about one inch to the right of the mid-line over the Rolandic sulcus, tracked down through the bone. A half-inch diphtherine was applied behind this, and an oval area of normal

bone $1\frac{1}{2}$ by 3 in. around the sinus was removed; the dura bulged strongly through the opening, and pulsation was barely perceptible. When the dura was opened the convolutions were found to be flattened and oedematous, but revealed no sign of inflammation. A small nick was then made in the dura where it had been adherent to the bone, and immediately a strong stream of greenish pus, about 3 oz., gushed out under considerable tension. The brain shrank like a deflated bag, and pulsation at once returned. A small drain was inserted and the wound closed, but marked collapse and respiratory distress followed and the child died a few hours afterwards.

Post Mortem.—There was a large abscess cavity in the pre- and post-Rolandic area of the right vertex, measuring 2 by 3 by $1\frac{1}{4}$ in. and half an inch below the cortex. Adjoining this on the mesial aspect of the brain was a smaller abscess cavity (see illustration). The walls were smooth and continuous with the brain substance. The rest of the brain was normal, except for a slight degree of internal hydrocephalus and some softening below the larger abscess. The lungs showed fibrosis of both apices, with doubtful signs of healed tubercle. The lungs were emphysematous, and there was pus in the larger and smaller bronchioles, but no bronchiectasis. *Staphylococcus aureus* was found in the pus from the brain and also from the bronchioles.

Remarks.

Abscess of the brain is exceedingly uncommon in so young a child; it is rarely seen under the age of 10 years. It is also uncommon for cerebral abscess to be secondary to lung disease, in spite of the fact that this cause is mentioned in all the text-books, and a priori one would expect to meet with it more frequently. Again, for a cerebral abscess to erode through the bone of the skull and form a tumour beneath the scalp is in our opinion an almost unique experience. It may be thought that this would not have occurred if the diagnosis had been made earlier, but at that time the only signs of cerebral disturbance were the Jacksonian fits. There was no optic neuritis, no vomiting, no headache except after a fit, and the child seemed quite well except for the signs of bronchitis. When the tumour first appeared it resembled a subperiosteal gumma, the edges being hard, while the centre fluctuated; this idea of a gumma was supported by the fact that the father was suffering from a syphilitic nerve lesion. The Wassermann reaction in the blood was negative, and the evacuated pus contained staphylococci. It was also peculiar that the abscess tracked directly through the bone to the exterior, without leaving any pus in the extradural space.

A CASE OF HYDATID DISEASE.

BY HAROLD C. LEES, M.B., B.S. LOND.,

HON. SURGEON, BLACKBURN AND EAST LANCASHIRE ROYAL INFIRMARY;

AND

JEFFREY RAMSAY, O.B.E., M.D. LOND.,

HON. ASSISTANT PHYSICIAN AND PATHOLOGIST, BLACKBURN AND EAST LANCASHIRE ROYAL INFIRMARY.

The following case is of interest owing to its unusual character.

The patient, a male, aged 50, formerly a collier, afterwards a weaver, and latterly a coal-heaver, was admitted to the Royal Infirmary, Blackburn, on Feb. 16th, 1923, for purposes of investigation, on account of having passed in the urine "a thick fleshy substance with a thin covering."

History of Present Condition.—Had no urinary symptoms previous to Feb. 10th, 1923. On this date he noticed slight pain and difficulty in micturating, and he passed the substance which is described in his own words above. He took it to his doctor, who thought that the substance in question might be an hydatid cyst. The patient states that he has lost weight considerably during the last few weeks, but can give no accurate figures.

Past History.—His left eye was destroyed by an accident in 1915. In July, 1922, he had an attack of pain in the lumbar region, probably a fibrositis, which lasted for three weeks. On Jan. 29th, 1923, he suffered from epigastric pain and constipation, which lasted for four days. With these exceptions he has had no illness or accident. Has never kept dogs or lived in a house in which they were kept. States that he has always been specially fond of watercress and has eaten largely of it since his boyhood.

Condition on Admission.—A moderately healthy-looking man of medium height and weight. Tongue coated. He is deaf in both ears and has a double set of artificial teeth. No abnormality found in heart or lungs. Systolic blood pressure 130, diastolic 80. Pupil reactions and eye movements in remaining eye normal, and knee-jerk present. On inspection, abdomen somewhat pendulous and distended, and lacks free movement on respiration. On palpation considerable gurgling, but no evidence of free fluid or of enlargement of liver or spleen. No abnormality can be discovered on bimanual examination of the kidneys. Percussion note over abdomen slightly tympanitic in character.

Examination of the blood shows the following: Haemoglobin, 85 per cent.; reds, 4,680,000; colour index, 0.9; no nucleated reds seen, no stippling; no megalocytes, microcytes, or poikilocytes.

White cells 12,000. Percentages: polymorphonuclears, 90; eosinophils, 3; small mononuclears, 4; large mononuclears, 3; myelocytes, 0; transitional forms, 0.

Urine: Specific gravity 1014; reaction acid; no albumin; no sugar. An occasional granular cast was seen.

Urea-elimination test: before urea, 2.5 per cent.; first hour, 2.5 per cent.; second hour, 3.2 per cent.

Examination of the substance passed in the urine on Feb. 10th showed a thin-walled collapsed cyst of about the size of a walnut, and three fragments of a cyst or cysts, the latter slightly blood-stained. Typical hooklets were found on microscopical examination.

Subsequent History.—On Feb. 18th, two days after admission to hospital, one cyst of the size of a walnut, three smaller complete cysts, and several fragments were passed in the urine, and hooklets were again found. On the 27th a cystoscopic examination was carried out, and no abnormality was discovered. This finding is not conclusive, since a thin-walled and freely movable cyst might evade the observation of the cystoscopist.

The passing of hydatid cysts per urethram is a rare occurrence. Osler records two cases out of a series of 241 cases of hydatid disease. In the present case it seems probable that the disease is localised in the kidney, and it is not proposed to adopt any active treatment unless other symptoms and signs appear.

A CASE OF COMPLETE INVERSION OF THE UTERUS OCCURRING IMMEDIATELY AFTER LABOUR.

BY H. COHEN, M.R.C.S. ENG.

THE following case presents points of interest.

The patient was a primigravida, aged 20, with half an inch shortening of the diagonal conjugate. Labour commenced at 10 P.M. on Dec. 19th, 1922. At 5.30 next morning, when she was first seen, the pains were regular and moderately strong, the os three-quarters dilated, the cervix dilatable, and the membranes unruptured, the presentation being L.O.P. After an hour the membranes were ruptured, but at 7.15 A.M., as the pains were becoming perceptibly weaker and as the head was not rotating, I sent for my colleague, Dr. B. J. B. Devine, who administered chloroform. The head was rotated, forceps applied, and the patient delivered in Walcher's position without a tear. Half an hour later the placenta was felt bulging the lower uterine segment, and the uterus being well contracted, the placenta was readily expressed. It was at once evident that complete inversion had taken place. The membranes were adherent to the fundus and were detached. Meanwhile the patient was still under the influence of the anæsthetic which was continued. A hot sterile cloth was applied to the exposed endometrium. There was practically no hæmorrhage, and after an interval, the patient's condition being good, the inversion was slowly reduced. Pituitrin (1 c.cm.) was injected and finally a hot intra-uterine douche given.

The uterus was kept under control for two hours, and very little bleeding occurred, though collapse of moderate degree was present. Pulse 120, but regular and of fair volume. During the following week the patient was kept under careful observation, rectal saline being given twice daily. There was a reactionary rise of temperature (101° F.) during the first 24 hours, but subsequently during the whole course of the puerperium the temperature did not vary from the normal by more than 1.5°, finally settling down to normal on the fifteenth day. Otherwise recovery was uneventful, the patient being kept in the recumbent position for a month.

My thanks are due to my colleague, Dr. Devine, for his advice and assistance in the course of the case.

ROYAL SOCIETY OF MEDICINE.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN.

BIRTH PALSIES.

AT a meeting of this section on May 25th, with Dr. ERIC PRITCHARD, the President, in the chair, there was an exhibition of cases and discussion on birth palsies.

Klumpke's Paralysis.

Dr. C. WORSTER-DROUGHT showed a female child, now aged 2 years, who when first seen in July, 1921, presented a complete flaccid paralysis of the right arm; all the muscles, including the deltoid and pectoralis major, were then involved, but not the scapular muscles. She was a full-term first child, a breech presentation, and it was stated that she had been born with the arms extended. None of the paralysed muscles reacted to faradism, but to galvanism there was some response in all the muscles except the intrinsic muscles of the hand. The child did not appear to feel pin-pricks below the elbow or on the inner side of the upper arm. It was evident that all the cords of the brachial plexus had been damaged by upward traction of the arm at birth, and the inner cord had suffered most. Under treatment by splintage (with the upper arm abducted to a right angle and the forearm supinated and flexed) with massage and galvanic baths gradual improvement had taken place. Voluntary movement appeared first in the extensors of the first and second fingers, and by March, 1922, all the muscles above the elbow reacted to faradism. At the present time the only muscles which remained paralysed were the intrinsic muscles of the hand; but the flexors of the wrist and fingers were still weak and there was no hand-grip. The attitude of the arm was that of external rotation and hyperpronation. Sensation was impaired on the inner side of the hand and forearm. It was apparent that all the roots had recovered except the eighth cervical (flexors of wrist and fingers) and first dorsal nerves (intrinsic muscles of hand). Dr. Worster-Drought pointed out that this form of birth paralysis, the Klumpke or lower arm type, was comparatively rare, over 80 per cent. of brachial birth palsies being of the Erb-Duchenne or upper arm type. According to Sherren recovery was rarely complete if there had been no improvement up to the age of 3 months. Dr. Worster-Drought asked for opinions as to the advisability or otherwise of exploring the brachial plexus.

Mr. GEORGE PERKINS showed the following two cases, both of which had been operated upon by Mr. W. R. Bristow, under whose care they were at St. Thomas's Hospital.

Erb-Duchenne Paralysis.

E. W., aged 7, was first seen in February, 1921. The right shoulder was then abducted and the forearm pronated. Abduction and external rotation of the shoulder and supination of the forearm were impossible either actively or passively, although faradic response was normal in all muscles. In May, 1921, the subscapularis tendon was divided through an open incision and the arm put up in plaster so that the fixed deformity was corrected. The splint remained on for a year, and he had since had physical treatment. The present state was as follows: Shoulder: abduction: full passive and half active range possible; external rotation: half passive range possible, but no active power. Elbow: full active and passive flexion present. Forearm: supination; half active and full passive range of movement present. All muscles were active and the joints normal. The result was, therefore, a very useful arm.

Spastic Hemiplegia.

In the second case there was a history of weakness of the right arm and leg from infancy, although there was no history of a difficult labour, and there was consequently some doubt as to whether or not the case was one of true birth palsy. This case, a girl aged 10, was first seen in January, 1921, when she exhibited a right-sided hemiplegia, the right foot being in fixed equinus and the right forearm in fixed pronation with the wrist in fixed flexion. In January, 1921, Stoffel's operation was performed on the right internal popliteal nerve; the two branches to the heads of the gastrocnemii and half the supply to the soleus muscle were divided. In March, 1921, Stoffel's operation was performed in the arm, the nerves supplying the flexor carpi radialis and the pronator radii teres being divided. Her present state was such that she could walk almost normally, but while there was a full passive range of movement in all the joints of the arm the range of active movement was less and there was marked muscular incoördination and athetosis. Mr. Perkins remarked that the difference in results in the arm and leg was largely due to the difficulty in persuading the child to make use of a hand which up till the time of operation had been useless, whereas the child, if it walked at all, must use and develop full function in the leg that had been operated on.

Dr. BERNARD MYERS commented on the wonderful results obtained by orthopaedic surgery in cases of spastic paraplegia, and quoted as an instance the case of a child, aged 7, with scissor-leg deformity, who after several operations by Sir Robert Jones could now walk, run, and even jump. He also described a case of spastic hemiplegia in a new-born child, which died very soon after birth after exhibiting intermittent apnoea of the inspiratory type. At the post-mortem examination punctiform hæmorrhages were found in the cerebral cortex visible to the naked eye. Hæmorrhage into the pneumotaxic centre in the lower pons was found microscopically, although not visible to the naked eye. He believed that such microscopic hæmorrhages might be quite common, and that their occurrence might explain the apparent absence of cause for cerebral birth palsies when the person who conducted the post-mortem examination was content with examination by the naked eye alone.

Statistics from L.C.C. Schools.

Dr. F. C. SHRUBSALL gave some figures regarding the presence of difficult labour and asphyxia at birth of cases of infantile hemiplegia and diplegia at the London County Council special schools. The history of 146 cases had been investigated; in 32 cases there was a history of difficult labour, in 11 cases there was a history of asphyxia in the child, and in the remaining cases there was no history of either. These figures corresponded fairly accurately with the percentages of difficult labour and of asphyxia in the histories of children taken at random in the same schools. As regards their mental condition, which was regarded as important from the point of view of treatment, cases of hemiplegia were of average or better than average mentality in 1 per cent. of cases, and below average or "borderline" in 59 per cent., while cases of diplegia were of average mentality in 15 per cent., and below average or "borderline" in the remaining 85 per cent. of cases.

Mr. MAX PAGE contrasted the conditions under which the upper and lower limbs normally functioned; he explained the comparative lack of success in operations on the upper limb. Operative interference in the upper limb was only useful for the reposition of joints, and was useless as a means of restoring the finer movements. In the lower limb, however, Stoffel's operation was very valuable, as the movements were coarse and almost automatic.

Dr. E. BELLINGHAM SMITH questioned whether injury at birth was the cause of all the so-called

"birth palsies." He pointed out that precisely similar conditions might be produced by polioencephalitis during infancy. Parents were apt to remember non-existent birth injuries if these were suggested as a cause of paralysis. The number of Dr. Shruballs' cases in which there was no history of birth injury or of asphyxia tended to strengthen his view that many of these cases were in fact cases of polioencephalitis. He suggested that Mr. Perkins's second case was also one of polioencephalitis.

Dr. WORSTER-DROUGHT agreed as to the difficulty of diagnosis. In addition to polioencephalitis congenital syphilis had to be considered.

Mr. PERKINS pointed out that the mentality of the patient had little bearing upon the success of operation on the legs; even an idiot could walk and any case of diplegia could be made to do so by means of Stoffel's operation. Whatever their ætiology the orthopaedic surgeon grouped these cases as "cerebral spastic paralysis," in which the upper motor neurone had lost its normal power of controlling muscular balance. As a result the stronger group of muscles in a limb overcame the weaker, thus producing a deformity which in time became fixed. The orthopaedic surgeon's aim was to restore muscular balance by cutting off a part of the nerve-supply to the stronger muscles.

SECTION OF EPIDEMIOLOGY AND STATE MEDICINE.

THE MORTALITY OF COAL AND METALLIFEROUS MINERS.

A MEETING of this section was held on May 25th Dr. R. J. REECE, the President, being in the chair.

Prof. E. L. COLLIS read a paper entitled *An Inquiry into the Mortality of Coal and Metalliferous Miners in England and Wales*. He remarked that the mining community consisted for the most part of a compact body of men who did not change their occupation, were employed underground in dimly illuminated and artificially ventilated workings, had to put forth considerable muscular energy, and were exposed to the dust of the materials worked. Notwithstanding a general similarity of working conditions, the rates of mortality of different groups of miners differed widely. In coal-mining, pneumonia, bronchitis, and accidents were responsible for rates of mortality considerably above the standard of all occupied males, diseases attributed to alcoholism and phthisis were, on the other hand, less deadly amongst coal-miners than in the standard population. When the separate coal-fields were considered it appeared that the rate of mortality in the Lancashire field much exceeded that in any other and was nearly double the rate of Nottinghamshire coal-miners. It would seem that although local conditions must be held to contribute something to the differences, inquiry within the industry was needed to ascertain why they were so accentuated, particularly perhaps in the instance of phthisis.

The age distribution of phthisis amongst coal-miners brought it into line with the type affecting workers exposed to silica dust, but the unusually low absolute prevalence of the disease needed explanation. Possibly Mavrogordato's work provided the clue; he exposed one group of guinea-pigs to silica dust alone, a second to silica dust followed by coal, and a third to silica dust preceded by coal. His results indicated that "once silica is fixed in the lung tissues, coal exerts no eliminative effect. If anything the influence is in an opposite direction, but that a prior or even simultaneous exposure to coal dust appears to set up a condition in the lung which is inimical to the fixation of silica." With regard to mortality attributable to alcoholism, the order of the fields did not correspond to their order in respect of other causes of death. The miner was a "convivial" rather than an "industrial" drinker, usually taking no alcohol until the day's work was over. There appeared to be a relation between the depth of working and the mortality from alcohol.

Bearing in mind the strenuous nature of the task and the heat of the workings, it might be that the provision of drinking water underground would appreciably lessen the convivial drinking amongst coal-miners. Cancer was not an exceptionally important cause of mortality amongst coal-miners, cancer of the stomach and liver was the only form which showed a rate appreciably above that of the standard.

Passing to the three forms of metalliferous mining, (1) Tin-mining, (2) lead-mining, (3) ironstone-mining, it was remarked that the two former stood out because not only was the general rate of mortality in each excessive, but in each the same groups of disease were prominent—viz., phthisis with respiratory diseases and Bright's disease. Veins of tin ore—which in this country occurred exclusively in Cornwall—not only contained quartz but lay in a rock largely made up of quartz; much dust was generated in the workings. The high rate and age distribution of phthisis were in accord with what was recognised to occur amongst men exposed to the dust of silica. Recent work by W. E. Gye, W. J. Purdy, and E. H. Kettle on the toxicity of colloidal silica lent interest to the somewhat high rates for Bright's disease. The conclusion suggested was that silica dust was gradually converted into soluble silica in the lungs and caused the well-known fibrotic changes, but some escaped into the blood to be excreted by the kidneys which were consequently similarly affected. Lead ore was found in different districts; at Greenside, where the veins occurred in a granite country rock, the phthisis mortality was excessive, but not at Keswick, where the ore occurred in a limestone rock. Phthisis among hæmatite miners appeared statistically to resemble in a modified way fibroid phthisis and might be due to oxide of iron. Other workers, such as boiler-makers, exposed to oxide of iron exhibited a similar statistical type. This distribution was not found in carbonate of iron miners. Alumina dust, judging from the mortality data for slate quarriers, resembled oxide of iron and silica in its effect on the lungs.

A point mentioned in connexion with the possible influence of coal dust in lowering the incidence of phthisis upon coal-miners was supported by certain facts from the ganister industry. Ganister was a quartzite rock found underlying coal and overlying fire clay. Best ganister, which contained over 95 per cent. of quartzite, was made into first-grade refractory bricks and other material used for lining steel furnaces. The dust to which the workers were exposed was nearly pure silica and their mortality from phthisis excessive. Impure ganister, which contained veins of fire clay, was made into second-grade refractory materials used for coke ovens. The dust contained about 80 per cent. pure silica, but the workers had no excessive mortality from phthisis. The theory had been put forward that the influence of coal was due to some organic substance and that this substance might be washed down from the coal into the underlying fire clay where it was retained, this accounting for the protective action of the fire clay; it might be that the substance was of a nature to prevent silica becoming colloidal. An interesting point in connexion with tuberculous silicosis, first noted amongst metalliferous miners, was its low power of infecting contacts not themselves exposed to silica dust, such as the wives and children of the miners.

Discussion.

The PRESIDENT remarked that one factor of the low mortality from phthisis of coal-miners might be their comparatively high standard of diet. Dr. R. J. Ewart—whose untimely death they all deplored—had called attention to the correspondence between the rising curve of food consumption and the decline of phthisis; it would be of interest to learn whether the Lancashire field where, from the tables shown, it seemed that the phthisis rate had varied little of recent years, differed in the matter of food consumption from the other fields.

Sir KENNETH GOADBY spoke of the high sickness rate experienced by miners.

Dr. J. BROWNLEE fully concurred with the reader of the paper in emphasising the chemical as opposed to the crudely physical theory of the mode of action of silica.

Dr. M. GREENWOOD wished to associate himself with the President in calling attention to the loss epidemiological science had sustained by the death of Dr. Ewart, a most brilliant and original-minded investigator.

Dr. D. McKAIL referred to the difficulty of interpreting accident statistics, and Dr. J. C. McVAIL urged the importance of making fuller use of the morbidity data in process of collection under the National Health Insurance rules.

Prof. COLLIS, in reply, paid a tribute to the work of Dr. Ewart, the news of whose death had saddened a pleasant evening.

SECTION OF OTOTOLOGY.

A MEETING of the section was held on May 18th, under the presidency of Sir CHARLES A. BALLANCE.

An Instrument for Assisting the Deaf.

Mr. RICHARD LAKE and Mr. W. M. MOLLISON exhibited and demonstrated an instrument with this object, produced by the Marconi Research Department, which was favourably commented on by the President. The improvement shown by this instrument on previous attempts was due to the developments in the amplification of sound by means of electrical circuits, such as those used in wireless telephony, having enabled the problem to be approached from a new angle. This apparatus is known as the Marconi Otophone, and consists of electrical amplifying circuits in a cabinet, to which are connected a sensitive microphone and a pair of head telephones. By the use of a long flexible cord, the cabinet and microphone can be stationary while the patient is free to move about. The total weight is 16 lb., and the current is derived from dry batteries inside the instrument. Three switches enable the amount of current supplied to the valves to be regulated, and the speech amplification can be adjusted to five degrees. The object of the instrument, it was explained, was not to give a very powerful effect on the ears of a deaf person, but to enable a deaf person to hear an ordinary conversation in a room. It is claimed that by it a conversation at a distance of 6 feet is clearly reproduced. It is proposed to supply the instrument only on medical recommendation.

Mr. Mollison said he did not know whether the instrument would be of benefit to cases of internal ear deafness, or only for otosclerosis and middle-ear deafness.

The PRESIDENT thought the instrument was a remarkable one, and that it would be much improved chiefly in regard to weight and the cutting out of extraneous sounds.

Cases and Specimens.

Among the cases and specimens shown were two by Mr. F. SYDENHAM and Dr. DAN MCKENZIE. The first was a girl, aged 16, who suffered from epidemic cerebro-spinal fever with acute suppuration of the middle ear. When admitted to hospital 14 months ago the girl was semi-comatose and apparently quite deaf. The temperature was 103.5° F., there was a discharge from both ears, pain in both mastoids and oedema on one side. A double Heath operation revealed only a little pus, nothing sufficient to account for the grave symptoms. A good recovery was made, but the deafness persisted. Tuning-forks were heard for only a few seconds by air and bone. The calor tests were negative. The meningeal infection was considered to be due to that of the middle ear. The second case was one in which a woman, aged 35, had a temporo-sphenoidal abscess successfully evacuated six years ago. The abscess was a chronic one, with thick walls, and the first serious seizure occurred

year after the operation. Recently these were becoming more frequent. Dr. C. O. Hawthorne regarded the seizures as probably epileptic.

Dr. MCKENZIE related the case of a boy, aged 8, who was the subject of otitic pterygo-maxillary abscess which had been induced by thrombo-phlebitis of the jugular bulb. His temperature, 102°F., was not lowered by an immediate radical mastoid operation. On reopening the wound two days later, a small amount of pus led to an abscess in front of the bony meatus. This was opened and drained and the lateral sinus explored, but the latter contained no clot. As the temperature still remained high, Dr. McKenzie exposed and resected the internal jugular vein; it was found to be thrombosed down to the lower border of the thyroid cartilage. Next day there were signs of cavernous sinus thrombosis, followed in two days by death. The course of the infection in this case was rare.

Mr. T. H. JUST showed a woman, aged 27, who had a brain abscess due to otitic infection, also a right temporo-sphenoidal abscess, which latter was not revealed by clinical signs. She had had otorrhoea and deafness on the right side since childhood, but no other symptoms until shortly before admission to hospital last year. She then suffered from headache and vomiting. Her temperature was 101.2°F., pulse 120, and she kept her neck rigid. A radical mastoid on the right side was done, and the mastoid was found to be acellular, but the roof of the antrum was carious and an extradural abscess was found just above the tegmen. In the exposed dura mater a sinus was found leading to an abscess in the brain. This was opened and drained by tubes, and a slow and uneventful recovery ensued.

Mr. SYDNEY SCOTT described an interesting case of a girl, aged 10, whose left temporo-sphenoidal abscess was finally diagnosed owing to the definite and persistent amnesia for names and objects. On draining this, the general condition, temperament, and memory rapidly improved. Now the child was very bright and quite well 18 months after the operation.

Mr. Scott also described in detail two cases of cerebellar abscess in patients aged respectively 17 and 7, one of whom was still in hospital, the other quite recovered.

Mr. MOLLISON showed a man, aged 42, whose vertigo was cured by opening the external semicircular canal. The man's succession of attacks of giddiness and vertigo commenced while he was driving a van. There seemed to be normal membranes in both ears, but he was practically deaf in the left. Caloric response was sluggish, especially on the left. The left semicircular canal was opened, and within four weeks of the operation the patient was free from vertigo and he could hear a whisper at 8 feet from the left ear.

The cases were fully discussed.

CARDIFF MEDICAL SOCIETY.

A MEETING of this Society was held on May 8th, Prof. E. J. MACLEAN, the President, being in the chair.

Dr. R. CAMERON read a paper on

Renal Inefficiency and its Clinical Detection.

He limited the scope of the subject to the inefficiency associated with chronic nephritis, into the pathological and clinical classification of which he entered in some detail. Discussing the diagnosis of chronic nephritis, he pointed out the necessity for investigating (1) the presence, severity, and progress of general clinical signs; (2) renal symptoms—dropsy, uræmia; (3) cardio-vascular symptoms; (4) examination of the urine; (5) certain renal efficiency tests. The general clinical symptoms to be noted were weakness, loss of flesh—which might be masked by oedema—severe headaches, vomiting, and gastro-intestinal symptoms, recurring attacks of bronchitis and oedema

of the lungs, with shortness of breath. In addition there might be added symptoms indicative of kidney mischief—e.g., dropsy, uræmia, and cardio-vascular changes.

Dropsy was a diagnostic feature in one form of chronic nephritis, absent in others. Its causation was not fully defined. It had been ascribed to defective glomerular activity, to hydræmia, to damage of capillary endothelium by retained poisons, and to acidæmia rendering the vessels unduly permeable. Retention of salt and depletion of proteins were now considered the deciding factors. Defective blood protein might be a contributory cause of dropsy. In chronic parenchymatous nephritis the daily drain of protein in the urine might be 10 per cent. of the total blood protein. Addition of protein to the diet where there was dropsy reduced the dropsy, presumably because it raised the osmotic pressure of the blood in opposition to the controlling osmotic pressure of the tissues. Perfusion experiments with Ringer's solution sometimes caused oedema, and this oedema was prevented by the addition of colloids to the fluid.

Uræmia was a name given to a group of symptoms affecting the central nervous, the respiratory, and the gastro-intestinal systems. It was only found associated with renal inefficiency, and its recognition was therefore important. It had been called the metabolic catastrophe of renal disease, and in chronic nephritis it appeared only when the huge reserve of secreting tubules and glomeruli had dwindled till the critical minimum point had been passed. The cerebral or nervous type of uræmia might show drowsiness leading to coma, or muscular twitchings or spasms leading to convulsions. Sudden mania occasionally occurred, but delusions were common. Hemiplegia, or monoplegia, or amaurosis also occurred. Minor manifestations were headache, insomnia, muscular cramps, itching, numbness, or tingling. In the respiratory type, paroxysmal dyspnoea—so-called uræmic asthma—was a frequent symptom, and sometimes the first symptom observed of chronic nephritis. It was apt to begin in the early morning, recurring regularly at that time and leaving the patient free during the day. Later, it might last throughout the 24 hours. It was distinguishable from the wheezy respiration of bronchial asthma and from the air-hunger of diabetes by a peculiar whistling or hissing sound. Cheyne-Stokes breathing was often a well-defined feature at a later stage. In the gastro-intestinal type the patient might exhibit persistent hiccough, nausea, vomiting of an uncontrollable nature, and choleraic diarrhoea. Uræmia was simulated by many other conditions, notably alcohol and opium poisoning, diabetes, epilepsy, and the onset of general paralysis, cerebral hæmorrhage, tumour, and meningitis. The history and concomitant symptoms helped in the diagnosis, but the blood-urea and urea-concentration tests were of most service.

Cardio-vascular changes were frequently the first signs to draw attention to the nephritic condition. Distinctive symptoms were shortness of breath and giddiness on rising, epistaxis, persistent headache, and insomnia. These led to detection of high blood pressure, arterio-sclerosis, and cardiac hypertrophy. The blood pressure might be 160–200 systolic and 110 diastolic. High blood pressure was, therefore, an important index both in diagnosis and prognosis, but was sometimes present where renal tests gave no indication of nephritis. Even here prognosis must be guarded, on account of a possible cerebral hæmorrhage. *Retinitis* was present in 15 to 20 per cent. of cases, was of serious prognostic significance, but not invariably a sign of imminent danger. An important new field of investigation had been opened up by the introduction of certain chemical tests—chiefly the diastase test, the blood-urea test, and the urea-concentration factor. Generally the urea-concentration factor was a check on the blood-urea, for if the latter was high the amount of urea passed should be high, and gradually increase above 1.5 to 2.5.

Treatment.—As to diet, a diseased organ should not be overworked. It might rather be said, "Do not give it the work it cannot do." In renal disease we had been taught to deny almost entirely protein food, since the kidneys were the organs chiefly responsible for nitrogenous excretion. In acute nephritis, where the functions were almost universally suspended for a limited period, it was reasonable to carry out the rule. In the chronic interstitial kidney—the azotæmic type—the kidney could excrete its nitrogen so long as not more than 94 g. of protein was taken per day. Chittenden, the apostle of nitrogenous economy, said that 60 g. is necessary to maintain nutrition. Therefore at least 60 g. should be taken, allowing a balance of 34 g. If 60 g. were not taken in the food, a large part of this would be sent to the kidney in any case from endogenous metabolism. If the urea-concentration test showed above 1.5, much more could be taken. 62 g. would allow one egg, $\frac{1}{4}$ lb. fish, and 2 oz. of meat, and bread and vegetables would bring it up to 94 g. In the hydræmic type alone large quantities of protein could be given, as it lessened the dropsy and altered the whole outlook in life for the patient, who had hitherto been starved to no purpose. On the other hand, in a dropsical patient, who also showed signs of uræmia, it was safer to have a urea-concentration test done repeatedly before loading his blood with amino-acids, the precursors of nitrogenous waste. A certain amount of protein he should have to replace tissue waste, but not too much to overtax his renal power. It was Epstein who suggested protein feeding for dropsy, and experience proved that it was a great help. Epstein's theory that dropsy is partly the result of deficient blood proteins was not, however, generally accepted, and H. Maclean had worked out tables showing that, concurrently with the disappearance of the dropsy and the feeding with protein, the blood proteins—albumin and globulin—were not always increased, though the blood-urea was. Hence it was possible that urea was the cause of the increased diuresis and removal of symptoms.

Mr. D. J. HARRIES showed a

Large Cavernous Angioma of the Face

in a man aged 24. It was present at birth, and had gradually got bigger. It now occupied an area corresponding to the sensory distribution of the third division of the fifth nerve on the left side. It involved the whole thickness of the left cheek below the level of the angle of the mouth, the left lower lip, and the anterior two-thirds of the left half of the tongue, and there was an offshoot running upwards in front of the ear to the level of the upper border of the pinna. On April 6th, 1923, the left external carotid and all the veins running down from the left side of the face were ligatured. On April 20th the opposite side was similarly treated. This had reduced the mass to about two-thirds of its original size. Mr. Harries hoped to show the case again, after trying the effects of electrolysis. The case was interesting in that it suggested that the growth of the angioma was controlled by the sensory branches of the third division of the fifth nerve. Its extent could not be explained in terms of vascular or vaso-motor distribution.

ERRATUM.—In the last issue of THE LANCET (p. 1057) it was stated that at the Medico-Legal Society on May 15th the chair was taken by Dr. M. A. Collins. The name should, of course, have been Sir William J. Collins.

NORTH-WESTERN TUBERCULOSIS SOCIETY.—A meeting will be held at 3 P.M. on June 7th at the Tuberculosis Offices, Joddrell-street, off Hardman-street, Deansgate, Manchester, when Dr. H. de Carle Woodcock, of Leeds, will read a paper on the Diagnosis and Treatment of Tuberculous Glands. Medical practitioners interested in the subject are invited to attend.

Reviews and Notices of Books.

MEMOIRS: WITH A FULL ACCOUNT OF THE GREAT MALARIA PROBLEM AND ITS SOLUTION.

By Colonel Sir RONALD ROSS, K.C.B., F.R.S.
London: John Murray. 1923. Pp. 547. 24s.

SOME 20 years ago Sir Ronald Ross proposed to himself to tell the story of the solution of the malaria problem, because the facts when disclosed would reveal one of the most dramatic episodes in the history of medicine. But professional and professorial duties, no less than numerous malaria expeditions, the writing of a text-book on the prevention of malaria, and, lastly, duties and responsibilities in connexion with the war, regularly interfered with his project. The book, as completed, has taken a different plan from that originally designed; it is addressed now to the general reader in the form of memoirs, in whose compilation we learn that the author has seldom trusted to memory alone, but has verified most of the details from documents. He admits that these were "generally scribbled in the heat of action," but though this may imply haste it implies also the virtues of a record made before forgetfulness could intervene. A more critical attitude might have been adopted, he allows, but he has preferred to leave what he holds as facts to speak for themselves, praying that the book will have something more than its medical interests to hold the reader.

The work is long and begins with the pedigree of its author upon the inference of descent from the last Earl of Ross, who was killed in the fourteenth century. In nearer times the interesting line is traced back on the male and female side through several generations of soldiers and Indian officers. The author's grandfather was Lieutenant-Colonel Hugh Ross, who died comparatively young at Cawnpore in 1838; his father, Sir Campbell Ross, K.C.B., was a distinguished Indian soldier, and his mother, Matilda Charlotte Elderton, was the daughter of a lawyer and landowner in London by his first wife Matilda Halford, this lady, on the face of it, having been connected with the ancient Halford family whose property passed in the reign of George IV. to Dr. Henry Vaughan—later well known, under the style of Sir Henry Halford as President of the Royal College of Physicians of London. Sir Ronald Ross describes his father as a typical soldier, straight, stern, downright, and experienced; he was also an expert artist in water colours. He married while home on furlough, and the author of the Memoirs, the eldest of his ten children was born in India, in May, 1857, three days after the Indian Mutiny broke out.

At the age of eight Ronald Ross was sent to his uncle in the Isle of Wight for health and education, and for five years was at a boarding school near Southampton where his chief progress, we learn, was made in geometry and drawing, though he was much interested in music and worked out for himself the laws of harmony, so that he was soon able to harmonise any melody in any key. In 1873 he was first in a England for drawing at the Oxford and Cambridge Local Examination. These early inclinations toward mathematics and art have remained throughout the author's life, so that in the preface of this book we find his malaria work described as an episode, a self-imposed duty, secondary in relation to the man's ambitions with which he started, and which he has always cherished. He elected to study medicine, and at the age of 17 was entered as a student at St. Bartholomew's Hospital. Here he was much attracted by physiology and the revelations of the microscope, continued his musical studies with enthusiasm, read a imposing amount of poetry, and decided that he would himself take seriously to verse, as well, apparently, as try his hand at sculpture. But Sir Campbell Ross indicated that it was time for him to get qualified, and in 1881, armed with the necessary diplomas, I

passed into the Indian Medical Service and departed for India. His descriptions of life in Madras, Burma, Bangalore, and other centres close the first part of the Memoirs with a vivid picture of service in India, and all this section is full of reference to writing in prose and poetry at which he enthusiastically toiled, and which resulted in the publication of two dramas in verse and a romance, which won approbation from well-known writers, but which earned no money.

The second section of the book deals with the subject of malaria, and sets out the problem, the experiments, their failures and successes, the circumstances of the discovery and of its proof, and Sir Ronald Ross has been at considerable pains to make a complicated and interesting story clear to the general public whom he is addressing. His labours were unavoidably, and perhaps avoidably, interrupted by official duties and other circumstances, and considering the length of time which the investigations lasted it was impossible that misinterpretation and misunderstanding should not sometimes occur, but the verdict on the supreme value of Sir Ronald Ross's work has never been challenged, and the honours and awards which he has received, as recorded in one of the appendices, make a list of which any man might be proud. It is impossible, therefore, not to regret some of the passages in this and in the third section of the book, but none the less we have here pregnant lessons for the public. Once again a great scientific research is shown to have succeeded in face of public apathy, the protagonists are found to receive little material support, and the wide economic bearing of the discovery, as influencing for the better the death-rates and life conditions of millions of people, goes largely unobserved at first.

Throughout all his assiduity at the special work which has won him world fame Sir Ronald Ross pursued his experiments in mathematics and his ideals in verse. He gives many excerpts from his poems and a catalogue of his mathematical papers in an appendix. And how devoted he has been to both pursuits is instanced by a phrase in the preface, already quoted, in which the study of malaria figures almost as a by-industry. The need to find the right word entailed by the mechanics of prosody must, however, have served Sir Ronald Ross well in scientific writing, while his mathematical studies had a definite outlet in his studies of pathometry.

The book is thoroughly well produced, and should obtain a gratifying reception from the public.

PSYCHOLOGY AND PSYCHOTHERAPY.

Some Applications of Psycho-analysis. By DR. OSKAR PFISTER, Pastor in Zurich, Switzerland. London: George Allen and Unwin. 1923. Pp. 352. 16s.

THIS is a collection of essays on varied aspects of psycho-analysis. Opening his subject with apologies Dr. Pfister claims for it a place in science and demonstrates that it can fill up the "enormous gaps" in orthodox psychology. The essays are uneven; that on the Psychology of Peace and War is inconclusive and drifts into simple eloquence which may have psychological value but is not psychology. In Psycho-analysis and Art the author, after the analysis of a neurotic artist and his pictures, deduces that the work of art has a double meaning; the latent meaning, often not recognised by the conscious mind of the artist, is yet his property, whilst the manifest meaning is accessible to others. In the chapter on philosophy Pfister departs from the empiricism of Freud and ventures into metaphysics. The relation of psycho-analysis to ethics he claims to be a constructive one and the chapter can be recommended to those who fear a destructive influence. Pfister's special work is among adolescents, and his description of the treatment of their psycho-neurotic manifestations brings up the question, which he has more definitely raised in other writings, whether this treatment shall be a part of medicine or of pedagogy.

The translation runs smoothly, but occasionally a strange statement (as, on p. 96, that the existence of love and hatred is a rationalisation) makes one suspect a translator's error. Dr. Pfister writes as a broad-minded Protestant pastor and his views are on the whole expressive of psycho-analytical orthodoxy; there are probably many people to whom such a combination should make a special appeal.

Group Psychology and the Analysis of the Ego. By SIGM. FREUD, M.D., LL.D. Authorised translation by JAMES STRACHEY. London: George Allen and Unwin. 1922. Pp. 134. 7s. 6d.

HERE Freud examines the conceptions of Trotter and McDougall, and of Le Bon in his "Psychologie des Foules," in the light of psycho-analytical theory. The herd instinct is postulated by Trotter as one of the primary instincts, and man's collective action, with its intensification of the emotions and inhibition of the intellect, differs so much from his actions as an individual that this postulate has been generally accepted. Freud, however, analyses the instinct into elements which are constituents of individual psychology, identification with other members of the herd and recognition of the leader as the dreaded primal father being the main elements. Suggestion, or suggestibility, which to some psychologists is an irreducible primary phenomenon akin to the herd instinct, is similarly resolved, and Freud defines suggestion as "a conviction which is not based upon perception and reasoning but upon an erotic tie." This expresses the well-known psycho-analytic view, but the analysis of the herd instinct is novel. A great part of Trotter's argument is based upon the existence of the instinct in lower animals, which Freud neither denies nor attempts to explain. To English psychologists this will appear as a serious omission in what is an important contribution to social psychology.

Beyond the Pleasure Principle. By SIGM. FREUD. Authorised translation by C. J. M. HUBBACK. London: George Allen and Unwin. 1922. Pp. 90. 6s.

IN this book Freud pursues a speculative path into what he calls meta-psychology and reaches the thought that the pleasure principle ultimately tends to keep the psychic apparatus free from excitation and thus subserves the death instinct. His thesis is frankly an intellectual exercise and is not easy to follow. He reflects (p. 76), "I might be asked whether I am myself convinced of the views here set forward, and if so, how far. My answer would be that I am neither convinced myself, nor am I seeking to arouse conviction in others." The book is addressed only to those fully acquainted with psycho-analytic theory.

L'OPOTHÉRAPIE DU PRATICIEN.

By L. LEMATTE, Docteur en Pharmacie; Membre de la Société de Médecine de Paris et de la Société de Thérapeutique. Paris: A. Maloine et Fils. 1923. Pp. 235. Fr. 5.

THIS little volume is intended as a guide to the practitioner in the uses of the various organotherapeutic preparations. Dr. Lematte is not an advocate of the administration of dried extracts except in the case of thyroid and parathyroid glands. He prefers glycerine extracts given hypodermically, for he considers that by this method only can the active principle of the gland be retained and the full physiological effect secured. A good deal of space is devoted to a description of the methods employed in preparing standardised liquid glandular products and the precautions necessary to ensure sterile extracts. The various uses to which these extracts are put are detailed and in each case authority is quoted for the recommendation. The author appears to have ample faith in the value of gland extracts in the treatment of various disorders.

PRACTICAL MORBID HISTOLOGY.

A Handbook for the Use of Students and Practitioners. By ROBERT DONALDSON, M.A., M.D., Ch.B., F.R.C.S.E., D.P.H., Lecturer in Pathology and in Forensic Medicine, St. George's Hospital Medical School; Pathologist and Curator of Museum, St. George's Hospital. With a Foreword by Sir HUMPHRY ROLLESTON, K.C.B., M.D. London: William Heinemann (Medical Books), Ltd. 1923. Pp. 364. 15s.

THIS book is intended for students beginning the study of morbid histology and for practitioners reading for the higher examinations. The first two chapters are devoted to inflammation in general and the specific reactions of tuberculosis, lymphadenoma, and syphilis. Then follow chapters dealing with the more important microscopic lesions of the various systems, including a chapter on neuropathology, which is much more complete than is usual in a book of this size. Tumours are described in the next half-dozen chapters, and there is adequate space devoted to histological methods and formulæ. An appendix on worm parasites and their ova will probably prove useful to students immediately before their examinations. Except for their tumours, there are no descriptions of the lesions of the genital organs, and the ductless glands are omitted altogether. In order to establish the necessary continuity between morbid histology and the broader aspects of pathology, the descriptions of the histological lesions are preceded by brief accounts of the general pathology of the conditions and their morbid anatomy, a practice which undoubtedly enhances the value of the book. Dr. Donaldson writes clearly and has selected his material with skill. If in one or two minor points he may be open to criticism, he has on the whole avoided successfully those faults into which one who has to teach dogmatically for the sake of brevity is prone to fall.

In one respect his book is unique: it contains no illustrations. This omission is defended partly on the count of expense, both in the Foreword and in the author's preface, but not very convincingly. A practical text-book on histology without illustrations implies not only a power of lucid exposition in the teacher which few are fortunate enough to possess, but also a degree of concentration and native intelligence in the student which can scarcely be expected, and it offends against all modern theories of education. Like most proverbs, that one which states that "there is no royal road to knowledge" is merely epigrammatic nonsense. Of course there is a royal road. It has been built for us by our predecessors, but since its margins are not always very clearly defined, teachers are necessary to guide us through and past the dangerous places. The traveller's powers are quite sufficiently taxed in keeping up with his guide; that his energies should be expended on unnecessary toil, and his progress delayed for the lack of a helping hand, is obviously unsound. An ideal text-book on histology would consist of figures and legends; the greater the ratio of the letterpress to the figures, the greater its fall from perfection.

While we differ from Dr. Donaldson on a point of educational doctrine, we are free to admit that the final judgment must rest with the student; on his decision the success or failure of this otherwise excellent book will depend, and it may well be that he will find in it all the help he requires for the elucidation and study of his histological preparations.

I BELIEVE IN GOD AND IN EVOLUTION.

Second edition. By W. W. KEEN, M.D. London and Philadelphia: J. B. Lippincott Company. 1923. Pp. 102. 4s. 6d.

THERE has lately been a curious revival in America of the Victorian notion that Darwin and the Bible are incompatible. Some wild Western State is, indeed, reported to have contemplated, perhaps even achieved,

legislation prohibiting the teaching of evolution in the schools. The veteran leader of American surgery put out this small book last year to combat this kind of reaction; it has evidently met a want, for a second edition has soon appeared. The proposal defended is sufficiently stated in the title. The book consists of 15 short chapters giving some of the points in man's structure which illustrate his evolutionary history, with brief expositions of the cell doctrine and other related matters. The text will persuade no one who is worth persuading that the idea of evolution is true unless they want to believe, any more than Paley's Evidences ever convinced anyone against his will of the truth of Christianity. What is significant is that a great American, who has spent a long life in the service of his profession and of his fellows, should come forward and say quite definitely that he does believe in God and in evolution too. There will be few persons who will be willing to brush aside such a piece of personal testimony without looking further into the matter.

PHYSIOLOGY OF REPRODUCTION.

Second edition. By FRANCIS H. A. MARSHALL, Sc.D. Camb., D.Sc. Edin., F.R.S., Fellow of Christ's College and Reader in Agricultural Physiology in the University of Cambridge. With contributions by WILLIAM CRAMER, Ph.D., D.Sc., M.R.C.S., L.R.C.P.; JAMES LOCHHEAD, O.B.E., M.A., M.D., F.R.C.S.E.; and CRESSWELL SHEARER, M.D., Sc.D., F.R.S. London: Longmans, Green and Co. 1922. Pp. 770. 36s.

THIS book, which has justly earned an international reputation, contains a scientific account of everything of importance which has been discovered or surmised concerning the reproductive functions in animals of all classes, but more particularly in mammalia. It will appeal to physiologists and zoologists, obstetricians and veterinarians, and impresses us as being the product of a lifetime of careful work, and the bibliography showing that the author has searched very widely for information. Few facts are to him too trivial to be included, and no problems too big for thorough discussion. The sections which relate to pregnancy, fertility, sterility, birth, sex determination, menstruation, and lactation are, naturally, of the greatest interest to medical readers; these and other wide subjects are practically treated, while the general outlook of the book is academic.

So well-written, well-published, and valuable a book, and, moreover, one already so well known, needs no further praise. The reputation gained by the first edition has been more than maintained in the present up-to-date version, to which the author's collaborators have contributed no insignificant part.

BOOKS FOR NURSES.

Obstetrical Nursing. By CAROLYN CONANT VAN BLARCOM, R.N. London: Macmillan and Co. 1922. With 200 illustrations and 8 charts. Pp. 558. 15s.

THIS is an interesting book written mainly for the purpose of widening the outlook of maternity nurses, and of teaching them that methods with which they may be unfamiliar may be just as efficacious and trustworthy as those which they have been taught in their own training school. Miss van Blarcom was for some time instructor in obstetrical nursing in the Johns Hopkins Hospital, and it is thus not surprising to find that the book contains a clear and most practical account of the subject. One of the features of the book is that a good deal of space is devoted to describing how results similar to those obtained in hospital can be obtained with improvised appliances in the patient's own home. The volume gives an interesting picture of the manner in which maternity nurses are trained in the best of the American training schools, and contains many points which will strike the English nurse as novel but none the less instructive.

While we have nothing but praise for the purely nursing portion of the book, there are some statements relating to midwifery practice to which we could hardly subscribe. The maternal mortality of placenta prævia in a well-conducted lying-in hospital is more nearly 4 than 40 per cent., and surely more mention might have been made of the commonest and in many instances the best method of treatment in such cases—namely, version. Very little is said of the more common variety of slight external accidental hæmorrhage and its treatment. The paragraph dealing with the treatment of more severe cases would give the nurse but little idea of what is usually done. The axis-traction forceps illustrated are of a very old pattern, and the statement that the introduction of bougies is generally followed by the onset of labour within 6–24 hours is unhappily far from the truth. In spite of these minor defects, however, we can fully commend this work, which might well be in the hands of all those who have to undertake the teaching of nurses in obstetrical nursing, and we congratulate the author.

Obstetrics for Nurses. By EVERETT DUDLEY PLASS, M.D., Obstetrician-in-Chief, Henry Ford Hospital, Detroit; formerly Associate Professor in Obstetrics, Johns Hopkins Medical School. London and New York: D. Appleton and Company. 1923. Pp. 410. 15s.

THIS book has been written to provide for nurses a simplified treatise on the more or less scientific side of the practice of midwifery. To those who object that the work is too theoretical for nurses the author would say that nurses form one of the best media by which the public can be educated on medical matters. It is doubtful, however, if the degree of general education of the ordinary nurse is sufficient to enable her to make use of such an advanced work as the one under review. It could be used with greater advantage by the average medical student. The book is largely based upon the teaching current at the Johns Hopkins Hospital and this is sufficient to indicate that it is founded on sound principles. A number of excellent illustrations, many of them from Dr. Whitridge Williams's large work on Obstetrics, add to the value of the text. In a book of this kind it is always interesting to see how the author deals with some of the graver emergencies of obstetric practice, such as the ante-partum hæmorrhages. With the section devoted to a description of the nurse's responsibility in such cases we are in entire agreement, although, naturally, we do not agree with all the recommendations as to treatment; these are in many ways controversial subjects and there is still much difference of opinion even among the experts. Nurses who have already some knowledge of the subject will find this book of great use in enabling them to extend and complete their bedside teaching.

Obstetrics for Nurses. Sixth edition. By JOSEPH B. DE LEE, A.M., M.D., Professor of Obstetrics at the Northwestern University Medical School, Chicago. London and Philadelphia: W. B. Saunders Company. 1922. Pp. 525. 15s.

THIS excellent little book has reached a sixth edition, clear proof of its worth and usefulness. The author has carefully revised and brought up to date this new edition. In view of the increasing performance of the operation of Cæsarean section the chapter dealing with this procedure has received considerable additions. As the practice of patients being delivered in maternity homes is becoming more and more prevalent more attention has been given to the recognised practice of the best of these institutions, and the technique of the Chicago Lying-in Hospital has been more fully presented. The balance between the two subjects to be considered in a book of this kind—namely, obstetrics for nurses and obstetric nursing—has been well struck, so that neither has been dealt with too fully to the detriment of the other.

We can cordially recommend this book to maternity nurses and midwives as informative and trustworthy.

JOURNALS.

QUARTERLY JOURNAL OF MICROSCOPICAL SCIENCE. Edited by Prof. GOODRICH, F.R.S. Nos. 264 and 265.—The two latest parts contain respectively six and seven memoirs which show the usual diversity of topic within the limits of zoology. Among the articles in No. 264 is one dealing with ovum-like bodies in the testis, by F. A. E. Crew and H. B. Fell, who show how cases of hermaphroditism may be wrongly described; for they illustrate in the testis of a number of mammals round bodies which show a most striking likeness to ova. These bodies are merely due to degenerative processes shown by the normal testicular cells. In No. 265 an important paper is that by W. N. F. Woodland on the Tapeworm genus *Amphilina*. These worms retain the non-strobilated condition of most other "flat worms." Besides giving a full account of the structure of the species *A. paragonopora*, the author surveys critically the other named species of the genus. Prof. T. T. Flynn deals with the "Yolk-Sac and Allantoic Placenta in Perameles," which was originally discovered by Prof. J. P. Hill to be the only marsupial genus with a proper allantoic placenta. In extending Prof. Hill's results the present author comes to the conclusion that the placenta of perameles is most like that of the carnivora among the Eutherian mammals, a point of great interest when the relationship of the extinct order Creodonta to both groups is borne in mind. Incidentally Prof. Flynn laments the approaching disappearance of marsupials of the Tasmanian fauna, and thinks that the developmental stages of the Thylacine will never be investigated, and that "it is extremely unlikely that detailed investigation will be possible in the case of *Sarcophilus*." An account of the foetal teeth of the sperm whale is communicated by Dr. F. E. Beddard; the foetus, only four and a half inches long, of this gigantic mammal, was obtained from whale-fishers in Natal by the well-known curator of Durban Museum, Mr. E. C. Chubb.

THE INDIAN JOURNAL OF MEDICAL RESEARCH for April contains 23 articles. R. McCarrison writes upon the Pathogenesis of Deficiency Disease with reference to the function of the adrenal gland, its relation to hydrogen-ion concentration, and the effect of heat, cold, and sunlight on the action of epinephrin.—H. E. Shortt has an article upon the Pathogenicity of Insect Flagellates to Vertebrates with special reference to *Herpetomonas denocephali*.—P. J. Barraud continues his revision of the culicine mosquitoes of India.—S. D. S. Greval contributes a preliminary report upon schistosomiasis in Arabia, from which it appears that both *S. hæmatobium* and *S. mansoni* occur in the hinterland.—U. N. Bramachari continues his articles on the Chemotherapy of Antimonial Compounds in Kala-azar.—F. W. Cragg writes on the distribution of Indian rat fleas and the zoophilism of anopheles in relation to the epidemiology of malaria in India, and together with C. S. Swaminath contributes some observations on the bionomics of *Xenopsylla astia*.—T. N. S. Raghavachari considers the Mills-Reincke phenomenon, or the indirect benefit conferred on a community by a protected water-supply, to be inapplicable to Indian conditions.—J. W. Cornwall writes on the Structure of the Salivary Pump in Certain Blood-sucking Insects, and S. R. Christophers describes a new East African mosquito *A. kingi*.—W. F. Harvey and H. W. Acton have examined the degree of efficacy of anti-rabic treatment, and the former has completed the ninth section of his series on Bacteriological and Laboratory Technique.—L. A. P. Anderson contributes a note on a fumigation method by hydrocyanic acid gas on a small scale.—R. H. Malone describes fallacies associated with the use of laboratory animals for isolating pathogenic micro-organisms.—J. Cunningham and J. A. Cruickshank consider a standard necessary for preparation of vaccine lymph, and describe a new

test.—C. A. Gill writes on his ability to predict malaria epidemics, R. H. Malone on the solubility of micro-organisms in bile, W. F. Harvey and K. R. K. Iyengar on the duration of protection after prophylactic inoculation.—H. E. Shortt has a record of kala-azar research work carried out in Shillong in 1922.—M. H. Sowerby gives an account of bovine tuberculosis in the Bombay Presidency.

ANNALES DE L'INSTITUT PASTEUR. Vol. XXXVII., No. 4, April, 1923.—This number opens with a review by M. Nicolle and E. Césari on the present methods of diagnosing pathogenic organisms. They note the difficulty of speaking strictly of species of bacteria, and point out that, on the other hand, the reactions of antigen and antibody connote "specific" groups sometimes of a different order. The difficulties in the way of identifying a given specimen of an organism may be very great or even insurmountable on account of loss (perhaps temporary) of certain characters.—E. Marchoux gives an interesting account of the clinical symptoms and pathological changes in a human case of a disease which he believes to have been identical with rat leprosy. The case had been diagnosed as an unusual form of human leprosy. The lesions much resembled leprosy, and were crowded with acid-fast bacilli, as may be seen figured in the

coloured plates. The disease was, however, experimentally reproduced in the rat. The patient died of secondary streptococcal infection.—G. Sanarelli contributes a paper on the experimental infection of animals (rabbits and guinea-pigs) with the cholera vibrio. He deals with the manner in which these microbes can enter the body, and details experiments to show that they can reach the blood through the buccal or nasal mucous membrane, and then, rapidly leaving the circulation, settle in the intestinal walls.—An important communication, by L. D. Walbum and J. Mörch, from the Serum Institute at Copenhagen describes the effect of intravenous injection of chloride of manganese and other metallic salts on the yield of antibodies in animals undergoing immunisation. Experiments were made on rabbits, goats, and horses which, under this form of auxiliary treatment, produced very much enhanced supplies of antitoxin or agglutinin. A considerable number of experiments are described in detail. Figures relating to the rate of production in units of antitoxin per c.cm. support the claim that the administration of these salts to horses in this way is a valuable addition to the previous methods in use. The irregularity in the production of antitoxin due to variations in the strength of the available toxin are held to have been excluded.

A FURTHER NOTE UPON THE PERIODICITY OF INFLUENZA.

BY JOHN BROWNLEE, M.D., D.Sc.,
DIRECTOR OF STATISTICS, NATIONAL INSTITUTE FOR
MEDICAL RESEARCH.

SOME time ago I published a note upon the periodicity of epidemics of influenza,¹ and I think that the present time admits of a second short statement regarding how far the 33 weeks periodicity in influenza outbreaks has been maintained. In 1918 and 1919 there were three large epidemics of influenza. From the crest of the July epidemic in 1918 to the crest of the epidemic in March, 1919, is 33 weeks, but there is no evidence of the further continuance of a periodicity starting from July, 1918.

If a 33 weeks period holds, then the start must be from the very large epidemic which culminated in the first week of November, 1918. In the accompanying table I give the weekly deaths from October of that year in a series of columns, indicating the epoch when an epidemic would be expected by a vertical line to the right of the figures. In the former statement it was noted that unless the expected period falls between the beginning of November and the middle of June an outbreak was very unlikely. From November, 1918, the first outbreak was due about the twenty-seventh week of 1919, and according to expectation no increase in the number of deaths is noted. The crest of the next epidemic was due in the eighth week of 1920, the epidemic actually culminating in the twelfth week. The next cycle should culminate in the forty-first week of the same year. Nothing is observed, as would be expected. In 1921, the twenty-second week marks the crest of the cycle. The greatest number of deaths in the epidemic this spring, however, occurred on the ninth or tenth week, though there was a slight recurrence which had its maximum in the nineteenth week. A further 33 weeks brings us to the third week of 1922, which, as seen from the table, marks the height of a very severe epidemic. The following cycle was due in September; as usual, at this season no effect in the death-rate is observed. The seventeenth week of this year is the next date of the epidemic crest, and it is easily seen that although during the last week there were still 207 deaths, this must be about the middle of the epidemic wave.

On evidence like this too much stress cannot be laid, but it is interesting to note that so far the cycle has held fairly true, only one epidemic occurring

independently. To myself, however, it would be more convincing if the cycles recurred in sequence to the epidemics of July, 1918, and March, 1919, rather than to the November epidemic, which for the season of its occurrence has, during the last 30 years, been a unique phenomenon.

¹ THE LANCET, Nov. 8th, 1919.

THE LANCET.

LONDON: SATURDAY, JUNE 2, 1923.

THE GENERAL MEDICAL COUNCIL.

THE opening of the 117th session of the General Medical Council on Tuesday last, May 29th, occurred on the day after the President, Sir DONALD MACALISTER, had completed the further term for which he had been elected as President. The academic position therefore was that his Address took the form of a communication setting forth the chief events with which the ex-President had dealt during the period that had elapsed since the last meeting. But as Sir DONALD MACALISTER'S re-election to the chair followed immediately, this communication became the official Address. This is the nineteenth Address which he has delivered from the chair during 34 years of consecutive service on the Council, and it needed no assurance from himself that his interest in the work of the Council is as keen now as it was when he first joined its membership, for his conduct of business in the chair has regularly and increasingly confirmed the fact. We congratulate the Council on giving a fresh proof of their conviction that no change of President is required.

As will be seen from another column Sir DONALD MACALISTER was able to report interesting progress in certain directions. He noted that legislation had taken place amending the Dangerous Drugs Act and in certain details the old Pharmacy Act of 1868, thereby abating the stringency of certain rules in regard to the scheduled drugs as they affected registered practitioners, while strengthening the penal code for criminal breach of the regulations. At this point he was able to express the sense of the Council of the assistance that had been given in shaping the new Act by Members of Parliament also registered medical practitioners, and there is no doubt that the House of Commons gained distinctly during the passage of this measure by the fact that throughout the considerable discussions men who actually knew where the dangers lay were able to speak of them from first-hand knowledge. The Dangerous Drugs Act might easily have become actually oppressive to practitioners. We congratulate Sir SYDNEY RUSSELL-WELLS, a member of the Council, and his medical colleagues in the House of Commons on having shown that the presence of members of our profession is a gain to the House and to the community. The closing paragraph of the Address deals with the statistics of the medical profession, which it is always well to have before us because of the two conflicting statements regularly made in public, that the medical profession is overcrowded, and that the medical profession is undermanned. It may be remembered that during the years 1916-19 there was a rapid rise in the number of registered medical students—namely, from 1875 to 3420, and that then the figures fell, until last year the total was much the same as it had been six years previously. The indications are that this figure—namely, something between 1800 and 1900—will be maintained unless the new regulations lead to its

diminution. The question is, whether this recruiting figure, on transformation into terms of registered medical practitioners, will maintain the medical profession in its proper numerical relation to the public. We believe, and we think the opinion is shared by those who have given serious thought to a serious matter, that the total of registered practitioners can be kept at its right proportion upon the material which is now finding its way into our ranks as students, but it is to be hoped that the organisation of the profession will lead to a better distribution of the personnel. For it is the faulty distribution of our practitioners which gives the conflicting impressions that their number is too large or too small.

BRITISH EMPIRE CANCER CAMPAIGN.

WE publish this week the appeal of the British Empire Cancer Campaign, which sets out briefly and well what may be considered the general opinion of enlightened persons in respect of cancer problems; apathy should be impossible in face of the destruction of life, but panic should be equally unwarranted, while so much has been done, and while so much is in the doing to clear the paths towards prevention and remedy. The mortality from cancer is given in the appeal, and the ignorance of causation is admitted to affect profoundly all big schemes in either direction. The general message of the appeal is that a great movement is needed under which medical work along all its branches, and lay work in all its developments, should be directed towards the amassing, collating, and sifting of evidence bearing upon causation. The new movement, it is expressly said, will supplant nothing good that is being done; it will not interfere with those who are already striving, and, be it remembered, striving with certain definite good results, to free mankind from one of its direst foes. On the contrary, it proposes to advance and supplement all individual and coördinated activities as they exist, forming in regard to these activities a general bond alike for the improvement of methods and the avoidance of overlapping. If certain experiments, directed towards clearing up one of the cancer problems, can be assisted either by analogous experiments under different conditions, or by different experiments under analogous conditions, valuable help to the researches will be afforded; and if upon the multiplication of these researches statistical methods can be brought to bear, in order to ascertain what common truths have emerged, every aspect of cancer research will gain in clearness. The variety of environment, or the variety of personal equation in the investigations, can be made allowance for, and all workers will feel that they stand upon more solid ground.

New movements cannot bring about the prevention of cancer because the prime effort is to be made in search for the cause. This is true, but while the scientific explorer cannot promise that the shaft which he sinks will reveal precisely the ore for which he is hunting, nothing valuable can be brought to the surface save by mining; and as a set-off to this uncertainty it must be remembered that unexpected treasure has been gathered in over and over again by experimental methods. But a proportion of the material results of any Imperial appeal of this sort should be devoted to the relief of conditions whose primal origin we do not know, for at any moment, if a method of relief proved successful, light might be shed upon every aspect of the case. It is the logical and desirable sequence of events in all courses of

therapy to know the cause, to remove it, and to obtain relief; but it is also logical to deduce from the measure of success with which a method has met the cause of the originating mischief. All intelligent clinical work is research work, and research work into cancer, when conducted at a hospital which is in touch with a first-rate teaching school, means to-day a combination of bedside and bench inquiry. At such an institution the best consensus of opinion upon a new procedure can be obtained. Methods that have been approved at special institutions can be employed by other clinicians, and the voices of the chemist and physiologist can be heard either upon points of dispute or in origination of plans made feasible by laboratory experiment. All the money obtained by the appeal should be used to search out the cause of cancer, but it is to be hoped that the Executive Council of the movement will recognise that a cause is best identified by showing that its removal leads to prevention or that its identification leads to improved clinical treatment.

Many of us know that discoveries in certain laboratories are giving good reason for encouragement. Therefore it is necessary—and this is recognised in the appeal—that support should be rendered from the beginning by the new fund to the endowments of the existing centres of cancer research. And all grants should in the main be given without stipulations or restrictions limiting the nature of the investigations for which they are to be used, since (the truism has already been indicated) it is impossible to say what line of research may lead to issues of practical value. Taking the cancer problem as a whole, the time for definite team-work has not yet come, for there is as yet no one road along which a team can be driven. But different circumscribed problems may arise which for some special reason have not been attacked by the existing institutions and which could be dealt with by a temporary organisation of ad hoc workers. In applied sanitation, in veterinary medicine, and in botany many things are occurring whose explanation might have a great bearing, by analogy, on the explanation of cancer, and along all such lines the new organisation proposes to act as a clearing-house and to instigate and support investigation. The Executive Council, whose names are appended to the appeal, we are informed, is provisional, in that necessary names can be added; this is good hearing, for strong as it is in certain directions, the absence from its consultations of the representatives of four important branches of science cannot escape attention. We understand that it is possible that the Medical Research Council may nominate, in consultation with the Royal Society, some men with first-hand knowledge of research work, certain of whom, we hope, will be available to act as chairmen of the working committees which it is proposed to set up. The British Empire Cancer Campaign includes on its executive many strong and well-selected persons, has behind it the great organisation of Red Cross and sound financial backing, while it arrives in reply to widely expressed public demand. Its success should therefore be assured.

GLASS OR METAL CONTAINERS?

IN an interesting book on "Botulism," which was reviewed in THE LANCET last week, Dr. GERALD LEIGHTON points out that it is only by efficient sterilisation that any foodstuff can be rendered absolutely safe when preserved. In discussing the temperatures required he raises the point as to

whether the containers themselves will stand the heat required, particularly if made of glass. The latest investigations show that the spores of *B. botulinus* are very resistant, and indeed, according to ESTY,¹ more so than those of the other anaerobes which he tested. While the heat resistance of different strains of *B. botulinus* varies considerably (and ESTY tested 112 different strains) their maximum resistance was as much as 330 minutes (five and a half hours) at 100° C. LEIGHTON quotes the California State Board of Health regulations, which require for large-size spinach tins heating for one hour at 252° F. (122° C.), and for olives 240° F. (116° C.) for not less than 40 minutes. In any question involving the temperatures of sterilisation for canned foods the type of container used is of importance. LEIGHTON discusses this question at some length, and points out that while the glass container is preferred by the average consumer, and has undoubted advantages, it is open to doubt whether these advantages are not outweighed by other adverse features, including the risk of fracture and the liability to under-sterilisation. In a valuable report to the Local Government Board on Preservatives in Meat Foods packed in Cans or Glass, Dr. A. W. J. MACFADDEN² pointed out that until recent years most of the preserved foods manufactured in this country were packed in tinplate receptacles, but that it has been supplanted of late years to a very large extent by glass and earthenware, more especially the former, in the case of goods intended for the home market. He added, "So much have glass-packed food materials advanced in public favour, that it appears to be profitable for certain home manufacturers to transfer imported canned meats, such as tongues, sardines, &c., from their tin receptacles into glass containers."

The respective merits of glass or tin are of considerable practical importance, and something can be said on either side. The main advantages in favour of glass containers are that they avoid metallic contamination, the purchaser can get a view, although a very partial and imperfect view, of what he is buying, they are more easily opened, and appear to be cleaner. The consumer often has the idea that food in a glass retainer is a superior type of product and so is willing to pay more for it when so vended. The advantages of tins are that they are cheaper, they cost much less in freightage rates, they are more readily sterilised with less risk of damage or fracture, and it is easier to make them hermetically tight. Our knowledge is sufficient to weigh critically these relative advantages and disadvantages and to advance an opinion on public health grounds as to which is to be preferred. Of the advantages of glass, apart from the real convenience of ease of opening, the only one of any importance is its avoidance of metallic contamination. The manufacture of tins has improved enormously, and with the modern type of tin the risk of lead poisoning is practically non-existent. The possibility of tin contamination remains, but it is evident that the danger of tin poisoning has been enormously exaggerated, and in spite of the vast increase in the consumption of tinned foods there are no recent proved cases of tin poisoning. Provided very old and stale tins are kept off the market, the

¹ J. R. Esty: American Journal of Public Health, February, 1923.

² A. W. J. MacFadden: Report No. 6 (Food) Local Government Board, 1908.

danger of tin poisoning hardly exists. From the scientific standpoint, not only in relation to botulism but also as affecting general bacterial contamination, the two factors of most importance are the efficiency of sterilisation and the problem of satisfactory closure. The sterilisation of canned foods is an extremely complicated problem, and is governed by many factors, most of which operate whether tin or glass containers are employed, and only those which affect this particular issue need be discussed. It has been pointed out that to make foods safe against the risk of botulism very high and sustained temperatures are necessary. It is true that it is possible for glass to be manufactured and used possessing high resistance to heat and which will stand these sustained high temperatures. Such special glass is considerably more costly, and unless definite regulations as to its use are made obligatory there is a strong inducement to manufacturers to use cheaper glass which may not stand the strain. The fact that a higher percentage of loss from fracture is to be anticipated is an ever-present inducement to the operative in charge of the sterilisation to avoid this by using lower temperatures, even if these are unauthorised. These points can be summed up by saying that the use of tin containers undoubtedly facilitates the task of the canner in submitting his food to safe sterilisation temperatures.

The greater ease with which tins, as compared with glass, can be made air-tight is probably of as great importance as the question of resistance to heat. The extensive work recently carried out for the Food Investigation Board has demonstrated the great significance of air access as a factor in spoilages. The point is of particular pertinence as regards the botulism risk. There is considerable evidence that the spores of *B. botulinus* alone—i.e., if unaccompanied by any living bacilli or toxin—are unable to originate the disease when introduced into the body by the mouth. Should, therefore, a few spores be present and remain undestroyed by any sterilisation given it is of fundamental importance to prevent their development into bacilli which will then produce toxins. In this connexion an air-tight container is an important factor, for even with such a strict anaerobe as *B. botulinus*, air access (for complicated reasons which need not be discussed) facilitates the development of the spores into bacilli with the production of their excessively poisonous toxin. The closure of tins has now reached a high degree of efficiency, and the percentage of tins not air-tight has for most products been reduced to very small proportions. With glass containers the problem is much more difficult, and from this point of view glass would seem to be decidedly inferior to the tin container. A consideration of all these factors strongly favours the view that the risk of harmful bacterial infection, including botulism, is decidedly less if tin containers are given the preference to glass.

UNIVERSITY OF LONDON.—A course of four advanced lectures on Tropical Hygiene will be given at St. Bartholomew's Hospital Medical College, West Smithfield, E.C. 1, by Dr. Andrew Balfour, at 5 P.M. on June 12th, 14th, 19th, and 21st. The subjects to be dealt with are: (1) Sojourners in the Tropics; (2) Problems of Acclimatisation; (3) Some Foodstuffs in the Tropics; (4) Modern Weapons against Insect-borne Diseases. The chair at the first lecture will be taken by Lord Stanmore. The lectures are addressed to advanced students of the University and to others interested in the subject. Admission is free, without ticket.

Annotations.

"Ne quid nimis."

THE EXTENSIONS AT UNIVERSITY COLLEGE MEDICAL SCHOOL.

THE new building at University College, London, arranged to house the departments of anatomy, histology, and embryology, which was inspected by the King and Queen on May 31st, is an imposing edifice. The building, designed by Prof. F. M. Simpson, F.R.I.B.A., faces Gower-street, and has a frontage of 154 feet, exclusive of the end gateway, which gives access to the south quadrangle. At the back it joins the physiology building. It consists of five floors, and in addition a sub-basement, which contains the heating chambers, coke cellars, tank, and specimen rooms. Of the five floors the lowest is devoted mainly to practical work in anatomy—that is, dissecting and radiography—the next floor to teaching accommodation and museums, the third and fourth to research in anatomy, histology, and embryology, and the top floor to teaching in microscopic anatomy. On the basement level the large top-lighted dissecting room adjoins rooms for the X ray examination of the living subject and for the study of X ray plates, so that students may be able, when dissecting any region of the body, to correlate the X ray appearance with what they see and handle in their dissections. On the ground floor are the museum and preparation room, a lecture theatre, fitted with the latest Zeiss epidiascope, a demonstration theatre, and rooms set apart for teaching and research in anthropology. The first floor contains a library, certain private and research rooms, and a laboratory for comparative neurology, where a collection of neurological preparations will be housed. Laboratories for embryology and histology occupy the second floor, where adequate accommodation for preserved material and microscopical preparations is also provided, besides a lecture room fitted with apparatus for projection of histological preparations and dark rooms for photographic work. The main students' laboratory for microscopical anatomy is situated on the third floor. It extends across the width of the building and is lighted by two continuous sky-lights facing north, as well as by windows facing the south quadrangle on the one side and Gower-street on the other. About 90 students can be accommodated in the laboratory, adjacent to which are preparation rooms and research laboratories. Accommodation for keeping live animals is also provided, and a room is set aside for the cinematographic study of animal movements by an apparatus by means of which it is possible to take up to 300 photographs per second of moving objects. Since the film can be projected at a rate of about 16 to 18 per second the whole movement is observed slowed 10 to 15 times, and by this method the analysis of reflex movements and muscular adjustments such as those of posture will be rendered possible. The X ray department is admirably equipped and the protection of all engaged in the work of the department has been carefully provided for. Part of the Rockefeller gift, which has made it possible to erect this model institution, has also been used to effect certain much-needed alterations and extensions in the departments of biochemistry, pharmacology, and physiology. On the ground floor the general biochemical laboratory receives an extension behind the anatomy theatre, and the biochemical research laboratories are also enlarged by taking in the whole ground floor of the pharmacology building. In pharmacology further accommodation for research is procured by dividing the present pharmacology lecture theatre into two laboratories, and this department receives also two extra laboratories on the second floor of the physiology building. A large part of the first, second, and third floors of the building connecting the present Institute of Physiology with the Institute of Anatomy is used

for increasing the accommodation for research in physiology. On the three upper floors there is free communication between the two institutes. From the basement a tunnel leads under Gower-street to connect with the Medical School. Space prevents a more detailed description of the structural features of the new institute, but enough has been said to show that the Rockefeller gift is being expended with wisdom and foresight. The development of a great medical school, it is true, depends less on spacious buildings than on tradition and teaching, but the stimulation of a well-equipped institution must go far towards the establishment and maintenance of those high ideals of medical education which the Rockefeller Foundation seek to propagate. We wish well to the school chosen to help in this great work, and have confidence that University College Medical School will be worthy of its buildings.

THE FECUNDITY OF THE HOOKWORM.

THE comprehensive American investigations into hookworm infection continue. In a recent number of the *American Journal of Hygiene* (Vol. III., No. 2) there appears an interesting article by N. R. Stoll on the relation between the number of eggs voided and the number of worms present in cases of hookworm infection. At first sight such a relation might seem of purely academic interest, but it is really of some practical importance, because it presents in a rough but concrete form some idea of the enormous task involved in the administrative control of hookworm disease. Basing his figures on careful counts of ten characteristic but varied cases, Stoll arrives at the conclusion that each female worm produces an average of 9000 eggs per day. The average number of female hookworms found in these cases was 240. From this one may gather that the average hookworm patient voids over two million hookworm eggs per day. In some cases on certain days the number may even reach five million. The effect of this extraordinary fecundity is modified, however, by the fact that possibly not more than a quarter of these eggs produce viable larvæ, but even this reduction leaves an almost incredible number of potentially infective larvæ. We cannot avoid viewing these figures with some dismay, but there is at least this element of satisfaction—namely, that the thorough cure of each individual patient removes an enormous amount of potential infection.

A NEW REVIEW OF ENDOCRINOLOGY.

WE have recently received the first number of the *Revue Française d'Endocrinologie*,¹ which is published in Paris, and edited by Prof. M. Lucien, of Nancy, and his assistants. In an introductory article Prof. E. Gley summarises the history of the contributions to this branch of medical science which have been made by his compatriots. It is indeed to Claude Bernard that we owe the first clear conception of the process of internal secretion; in 1859 he wrote: "There exists a group of organs resembling glands, but differing from them in that having no excretory ducts their secretions are poured into the blood-stream itself." During the same period the pioneer researches of Brown-Séquard aroused the interest of all physiologists in this subject. Since then there has been a continual output of careful and illuminating research by French investigators; it is only necessary to mention the work of R. Lépine on diabetes, of P. Langlois on adrenalectomy, of Pierre Marie on diseases of the pituitary gland, and the numerous researches of Prof. Gley himself, to demonstrate the importance of the French contributions to our knowledge. Inspired by such a history of national achievement we feel sure that the new journal will contain matter of interest and importance; and the contents of the opening number encourage such a belief. E. Sergent and P. Oury give a detailed account

of a case of acute adrenal insufficiency. L. Cuénot discusses the interesting question of the relation of the internal secretions to heredity; and Dr. Maclaure describes the present possibilities of glandular grafting. In addition there is an epitome of the more important recent medical literature dealing with endocrinology in all its aspects. There is one further point to be noted. In the advertisement columns of the new journal we find announcements, by a dozen or more commercial firms, of products derived from animal tissues, which science at the present day tells us to be either of unknown action or else inert. The multiplication and exploitation of products of this nature has tended to throw disrepute on the whole subject, and at least one important journal devoted to endocrinology edits its advertisement columns even more carefully than its scientific text. It is to be hoped that future numbers may contain less clamorous announcements of expensive extracts of heart-muscle, gastric mucosa, spleen, placenta, lung, lymphatic glands, and other tissues which respectable cooks reject, and food-controllers classify as "offal."

NEUROTROPIC STRAINS OF SPIROCHÆTA PALLIDA.

LONG before the causal organism of syphilis was known, the connexion between general paralysis of the insane and this disease was well recognised. In France, especially under the influence of L. Fournier, it was held that this connexion was a constant one, but in this country the relationship of the two diseases, although recognised as close, was not always conceded to be invariable. With increasingly efficient methods of demonstrating the spirochæte, and especially as a consequence of the introduction of the Wassermann reaction, the causal relationship of syphilis to general paralysis became more and more generally admitted until, with locomotor ataxia, the disease became classified as quaternary or para-syphilis. Nevertheless there have always remained many lacunæ in our knowledge, and peculiarities in these diseases which mark them off from the other manifestations of syphilis. Syphilis of the brain, gummatous in form, may occur and be comparable with the disease in other parenchymatous organs, but the lesions of general paralysis and tabes are peculiar in that they are degenerative instead of formative as are the other syphilitic lesions with which we are acquainted. There is, further, a definite lack of relationship, amounting to an actual dissociation, between the gummatous manifestations of syphilis and these two dreaded quaternary forms. It is, in fact, rare to find any signs of active or past tertiary lesions upon the cadaver of a general paralytic. These peculiarities have marked off para-syphilis as an entity with special features, and the theory gradually took shape, at the hands of many writers, that this particular manifestation of syphilis is due to a type of treponema having special affinities for the central nervous system. As knowledge of the spirochætes has progressed, variations in the character and behaviour of different strains have come to light which suggest that here, as with so many groups of pathogenic organisms—e.g., the pneumococci, meningococci, and spirilla of relapsing fever—we may meet with varieties having different properties and degrees of pathogenicity within the pallida group. An example of two strains having quite different pathogenic abilities for rabbits, and, what is particularly striking, failing to induce in these animals immunity against each other, has been quoted by Fournier and A. Schwartz in a recent number of the *Annales de la Pasteur Institute*.¹ The question of the existence of special neurotropic strains of the syphilitic spirochæte was taken up by C. Levaditi and A. Marie in 1919, and recently, returning to the subject, they claim that similar variations in virulence to those

¹ Paris: Gaston Doin. Bi-monthly. Fr.5.

¹ L. Fournier and A. Schwartz: Pléuralité des tréponèmes. *Annales de l'Institut Pasteur*, vol. xxxvii., No. 2, February, 1923.

which we have just mentioned are associated with such properties in spirochaetes as give them special affinities for the nervous system or the cutaneous and visceral organs, and after infection will tend to cause general paralysis on the one hand or gummatous lesions on the other.² The strains of spirochaetes which these workers consider neurotropic, which have been obtained from cases of general paralysis, cause only mild cutaneous lesions in the rabbit, whereas strains which they regard as dermatotropic tend to give rise to more severe lesions. The validity of many experiments on these lines has been called in question by the discovery of a spontaneous genital disease of rabbits, due to *S. cuniculi*, an organism morphologically indistinguishable from *S. pallida*. The further experiments of Levaditi and Marie show a complete lack of relationship between *S. cuniculi* and *S. pallida* of chances. They do not, however, appear to have absolutely established a like independence between their neurotropic spirochaete and *S. cuniculi*, although they make out a partial claim to have done so; for this reason judgment upon their results must be suspended for the present, although their great interest is not affected. The distinction between the neurotropic and common strains of the syphilitic spirochaete is based upon differences in the results of rabbit inoculations and upon an absence of the capacity of the one variety to render an animal resistant to infection by a strain of the other, several experiments being quoted to illustrate this absence of crossed immunity. The sum of these results and the often striking clinical facts which stand in relationship to them, amongst which we must include the much quoted frequency of parasyphilitic troubles in persons who have contracted their syphilis from the same source, is summarised thus: "Parasyphilis is a separate and distinct type of the specific infection, and is due to strains of treponemata which differ biologically and morphologically from those which are found in the commoner cutaneous, mucous, or visceral manifestations of the disease."

RADIUM IN THE TREATMENT OF CANCER OF THE UTERUS.

THE recent discussion at the Société de Chirurgie, reported in *Paris Médical* for May 5th, showed very plainly that whatever the prospects of radium treatment may be, its present position is very insecure, not merely as a substitute for operative treatment, but even as a supplement thereto. At first sight the time might seem to have come when the claims of radium treatment of cancer of the uterus might be settled, one way or the other. It has, indeed, been given a trial for many years. But so long as the technique of radium treatment is improving, trials in the past cannot be considered as fair, and it is probable that many years must yet pass before the technique has reached that stage of perfection which the operative treatment of cancer of the uterus was so long in attaining. There is yet another reason why we cannot at present form an equitable opinion of the merits of radium in this matter; many years must elapse before its immediate good effects can be proved to be permanent. At the meeting to which we have referred, Dr. Gosset and Dr. Robert Monod discussed the value of radium treatment as a supplement to operative treatment, and Dr. Monod gave an account of 30 cases—most of them bad cases—which he had operated on, supplementing operative with radium treatment. He had only two operative deaths, and he had found that a preliminary course of radium treatment had greatly facilitated the subsequent operation, a less radical hysterectomy than Wertheim's being performed. Microscopic examination of portions of the cervix excised before and after radium treatment had been made, and in 25 cases the second examination showed complete disappearance of the new growth. These two speakers were therefore very favourably impressed

by the combination of radium with operative treatment—a combination which they considered a very real advance. During the discussion which followed they received considerable support, but one speaker, Dr. Faure, gave this combined procedure only his partial approval. He believed that in certain inoperable cases radium treatment could render them operable, but he doubted whether cases already operable derived appreciable benefit from a pre-operative course of radium treatment. Of 33 cases operated on without radium treatment, 14 had ended in recovery. Of 44 cases treated by both radium and operation, 22 had ended in recovery and 22 in relapse. The comparison of these two series was thus hardly in favour of the combined method. Another speaker was not inclined to use radium before operation in operable cases, but he was in favour of post-operative radium treatment. Yet another speaker had given up post-operative radium treatment to return to pre-operative applications of radium. It is evident from the report of this discussion that the problem dealt with is still very far from a final solution.

MEDICINE IN THE ORIENT.

A STRIKING instance of the catholicity of scientific medicine is afforded by the issue of the new *Journal of Oriental Medicine*, the organ of the Oriental Medical Association of Manchuria. This journal, which is edited by Dr. T. Suzuki and Dr. J. Murakami, is to be published quarterly. The first number contains contributions in Chinese, English, and German. Up to the year of the establishment of the Republic in 1911 medicine in China was in a very backward state; when it is remembered that anyone can practise medicine in that country without the possession of a diploma it might be imagined that little or no amelioration of the conditions of things has since taken place. This, however, is not so, for with the Republic a new era in modern preventive medicine commenced, and steady progress has since been maintained. One of the first things which attracted the attention of the new Republic was the success of Western methods of treatment in the suppression of pneumonic plague in Manchuria in contrast with the results of crude and haphazard native methods, and as a result the North Manchurian Plague Prevention Service was established. This consisted of hospitals at Harbin, the commercial centre of North Manchuria and the principal focus of infection in 1911, at Tsitsihar, Sansing, Newchwang, Taheiho, Manchouli, and Lahasusu. In 1913 a presidential mandate was issued authorising the dissection of dead bodies in China, whilst sanction was given for the cremation of cadavers. In the following year a National Medical Association was founded with 30 medical graduates from European, American, Chinese, and Japanese colleges as a nucleus. The membership grew rapidly, and several medical conferences have been held under its auspices. In 1915 a mandate was issued recognising Western medicine as the proper standard of medical practice in China, by which anyone practising medicine in the country will be required to produce a certificate from the police, and since then hospitals and medical colleges have arisen in different parts of the country. A feature of the great progress made has been the increasing coöperation of Chinese and foreigners; missionary institutions invite more and more the assistance of Chinese colleagues, many of the native doctors having received a first-class training abroad. Among other evidences of progress has been the formation of a Terminology Committee to determine medical terms for use throughout China, and the series of resolutions passed at the fourth biennial conference of the National Medical Association of China last year, one of which requested in effect the Central Government to establish a legally qualified medical profession.

In the eighth year of the Republic a Central Epidemic Prevention Bureau was founded by means of the surplus of the fund raised to suppress the

² C. Levaditi and A. Marie; *Pleuralté des virus Syphilitiques*, *ibid.*

epidemic of pneumonic plague then raging in the northern provinces. The bureau has attracted numbers of Chinese medical men interested in public health work, and has furnished doctors for field work during various epidemics of cholera, pneumonic plague, and typhus occurring since its foundation. In 1921 a reorganisation of the bureau took place; an annual maintenance grant was obtained from Maritime Customs revenue, and a Medical International Board of Managers—having at its head Dr. S. H. Chüan, formerly Medical Director-General of the Chinese Army—was created and took over the direction of the bureau. The latter now possesses two departments, one devoted to laboratory work, the other to field service. The first bulletin of the bureau, written by Dr. Edgar T. H. Tsen, head of the laboratory department, printed in English and bearing the title "Notes on Biologic Therapeutics," appeared in January of this year. Dr. Chüan contributes a general foreword, and three other members of the International Board write introductory notes in English, Chinese, and French respectively. The various sections of the bulletin deal with methods of injection, serum reaction, general and particular considerations of vaccines and sera, and diphtheria toxin and toxin-antitoxin. Appendices contain information relating to the field service department, charges for various laboratory examinations, and the prices of biological products. No better evidence of the progress of medicine in the Orient could be desired than these two publications. The difficulties which faced the pioneers of Western medicine during the earliest days of the now well-advanced transitional period are clearly described in a chapter on Medical Education in China, contributed by Dr. George Hadden, of Changsha, to a recent publication of the Student Christian Movement,¹ which is described as a series of open letters on professional subjects from missionary doctors practising abroad addressed to their colleagues at home. Another of these chapters, by Dr. G. Duncan Whyte, of Swatow, contains a useful reminder that "while . . . there is much that is ludicrous and a great deal that is dangerous in (indigenous) Chinese medicine, yet many of the fundamental ideas that actuate the native doctor are very sound, and some of his drugs are most useful."

ÆTIOLOGY AND PROGNOSIS OF CIRRHOSIS OF THE LIVER.

AN important monograph has recently been published by Prof. S. Laache,² of the University of Christiania, on cirrhosis of the liver. His material consists of 44 cases, 34 of which came to necropsy. During the 32 years in which these cases occurred, 16,000 patients were treated in Prof. Laache's medical wards, and he accordingly estimates the incidence of cirrhosis of the liver among in-patients in medical wards at 0.28 per cent. This ratio is surprisingly low. With regard to the ætiology, there was a history of alcoholism only in 39 per cent., and all the patients giving a history of alcoholism were males. Not one of the 14 women suffering from cirrhosis of the liver confessed to alcoholism, and the questions therefore arise: (1) Are men more truthful than women when questioned on this rather tender subject? (2) Do men drink much more alcohol than women? (3) Is the male liver more susceptible to alcohol than the female liver? These are questions to which Prof. Laache has found no final answer, and it is significant that in as many as 12 of the 14 cases of cirrhosis of the liver in women its cause remained obscure. It was also obscure in many of the male cases, and as Prof. Laache points out, only a minute fraction of bibulous males suffer from cirrhosis of the liver, and the development of this disease must therefore probably depend on a certain predisposi-

tion, without which alcohol cannot provoke cirrhosis. This point is well worth bearing in mind when the present decline in the incidence of cirrhosis of the liver is correlated with a real or supposed decline in the consumption of alcoholic liquors. With regard to prognosis, Prof. Laache confirms the old observation that ascites is an ominous sign. It was present in 81 per cent. of the 26 cases of atrophic cirrhosis coming to necropsy, and the duration of life after the development of ascites was, on the average, only 10 to 12 months for men and only five to six months for women. The longest span of life after the development of ascites was only 30 months. Statistics such as these are not encouraging, and they suggest that cirrhosis of the liver with ascites is a hopelessly terminal stage, or that the treatment hitherto advocated is hopelessly inadequate. Paracentesis abdominis is but a symptomatic remedy, and in Prof. Laache's experience it may sometimes do more harm than good; in one of his cases hæmatemesis followed this operation. A drug which he has found remarkably effective in some cases is calomel, and he is also in favour of a salt-free, lacto-vegetarian diet. But in view of the ultimate results in the majority of his cases there would seem to be ample scope for therapeutic reforms in this field.

THE PSYCHOLOGY OF EPILEPSY.

ON May 24th, under the auspices of the University of London, Dr. E. T. Wiersma, Professor at the Psychiatric and Neurologic Clinic at Groningen, delivered at the Royal Society of Medicine an Anglo-Batavian lecture on the Psychology of Epilepsy. He gave an admirable summary of his researches into the perceptual processes, the fluctuations of attention, and the reaction times in epileptics. Experiments were made with respect to the "just noticeable" perceptions of sound and light in a number of epileptics, and he found that the results were most marked when fits were imminent, and were reduced when the patient was under the influence of bromide. He also exhibited diagrams of statistics relating to the mental and moral characteristics of epileptics as compared with normal people, and gave reasoned arguments for the conclusions to which he had arrived. It is noteworthy that exact psychological methods are being pursued by psychiatrists in the difficult problems of epilepsy and the psychoses, and no doubt much may be achieved in this direction towards a further elucidation of their origin. Dr. Wiersma traced the relationship of epilepsy to normal sleep; in the last-named condition some persons had a tendency to muscular startings before slumber. This habit, indeed, was frequently to be observed in children and animals. Hypnagogic hallucinations and nocturnal fears bore a close resemblance to epileptic equivalents, and similar phenomena were to be seen in disturbances of consciousness from other causes such as chloroform anaesthesia and alcoholism, which Dr. Wiersma regarded as links in the chain of the stage from epilepsy to the normal. He placed insistence on two phenomena which occurred in preoccupied or fatigued individuals and which appeared in aggravated form in epileptics—viz., "fausse reconnaissance" or the consciousness of having experienced present perceptions in the past, and "depersonalisation" or the failure to recognise actual perceptions with consequent disorientating effects. These might, no doubt, be assumed to arise through transient dissociation. Discussing epileptic characteristics, Dr. Wiersma endeavoured to establish a connexion with normal traits, and gave an account of an interesting series of percentage figures compiled from an investigation of 2523 normal persons. This was conducted by means of a list of 90 questions forwarded to Dutch practitioners, who were asked to send replies with respect to the mental "make up" of normal individuals well known to them. The questions included inquiries into capacity for comprehension, practical applications of common sense, breadth of mental vision, originality of ideas,

¹ Medical Practice in Africa and the East. Edited by Hugh Martin, M.A., and H. H. Weir, M.A., M.B., with an introduction by Stephen Paget, F.R.C.S. London: Student Christian Movement. 1923. 4s.

² Norsk Magazin for Lægevidenskaben, April, 1923.

verbosity, inclination to repetition, perceptive acuity, memory, mental reserve, wit, stubbornness, irritability, moodiness, self-satisfaction, conflict between thought and action, and so on. From this compilation Dr. Wiersma had divided the individuals into two main groups—viz., normally active persons and the absent-minded—the latter being prone to be inactive, losing grip on the outer world and its restraining influence on temptation, ill-at-ease with their fellow-men, and wandering in their thoughts. Dr. Wiersma's conclusion is that the absent-minded class represents transition between the normal and epileptic sections of the community. The fundamental nature of epilepsy he regards as due to an inherent failure adequately to assimilate impressions from the external world and holds that the convulsions, equivalents, and mental and moral characteristics associated with epilepsy are secondary and dependent phenomena.

THE MAUDSLEY LECTURE.

WHEN the Maudsley Lectureship was instituted in 1919 it was laid down that while the lecturer must have made contributions of well-recognised importance and value bearing on the knowledge of mind and its disorders, he might be of any nationality or of either sex. Sir James Crichton-Browne, who delivered the first lecture, dealt with the modern combination of laboratory and clinical work and the necessity of founding mental hospitals, and his lecture included a critical conspectus of psycho-analysis and psychotherapy. Last year Sir Maurice Craig took as his subject *Some Aspects of Education in Relation to Mental Disorder*, his key-note being Maudsley's remark that "there are not many natures predisposed to insanity but might be saved from it were they placed in their earliest days in exactly those circumstances and subject to exactly that training most fitted to counteract that innate infirmity." This year a distinguished visitor from the Dominions, Prof. C. K. Clarke of Toronto, was invited to deliver the lecture, of which we give an abstract on a later page of this issue. Prof. Clarke dealt as was natural with the special needs and conditions of a developing country, starting from the unfortunate fact that the host of immigrants drifting from the Old World contain an undue proportion of defectives and mentally diseased persons. He described the work of the Canadian National Committee for Mental Training which he directs, frankly admitting that its first function is to educate people to a knowledge of the importance of having well educated psychiatrists abroad in the community—with the idea of keeping prevention of mental disorder before the public mind, and its second to scan school populations with skilled eye in the hope of forestalling the thousand-and-one tragedies seen to-day. Dr. J. G. Soutar, in proposing the vote of thanks to Prof. Clarke, welcomed his address for its helpfulness and hopefulness. The lecturer's enthusiasm had driven without stampeding him, and it might well be true that Canada could face psychological problems with greater freedom, being less hampered by tradition and entrenched in pre-conceptions than the mother country.

PRESERVATIVES IN FOOD.

FRESH point has been given to the need for further control of preservatives added to our daily food by the appearance of Dr. W. J. Howarth's report for the year 1922 on the health of the City of London. During that year nearly 1000 samples of food or drugs were submitted to the public analyst for examination, and of these more than 11 per cent. were found to be adulterated, the substances being very various, as the following list shows: Coffee essence, milk, borax, butter, British wines, margarine, tinned spinach, honey, gelatin, lemon curd, cider, Gregory powder, whisky, preserved cream, sauce, mustard, rum, cream, table jelly. The list shows a wide field of sophistication, although Dr. Howarth believes it to be not greater in the City area than elsewhere, his method of group-sampling tending to give higher figures than

random sampling would. However, he regarded the situation as disquieting enough, as we have recently pointed out,¹ and the position fully justifies the plea of a proposed deputation to the Minister of Health, asking for the speedy introduction of legislation to notify and limit the presence of preservatives in food. This deputation, which included representatives of nine societies and a number of medical officers of health and others who have taken special interest in the matter of pure food, received the gratifying assurance that a Committee on the Use of Preservatives was in course of appointment. It is unfortunate that the only official action to be taken on the recommendations of the Departmental Committee of 1890 has been the issue of the Milk and Cream Regulations (1912 and 1917), prohibiting entirely the addition of preservatives to milk and limiting the amount of boric acid or hydrogen peroxide which may be added to cream, making obligatory an announcement of their presence on the label, and a further prohibition under the Foreign Meat Regulations of the importation of certain meat foods containing preservatives. But outside these there is a wide field for action. Laxity on the part of local authorities cannot, however, be entirely due to lack of powers, for the 5 administrative counties and 13 county boroughs, in which during recent years no sampling whatever has been done for the discovery of preservatives, have, as a matter of fact, possessed during that period full powers under the Milk and Cream Regulations. It is good fortune that just at this moment should appear a new edition (the seventh) of Bell's "Sale of Food and Drugs Acts"² which Mr. C. F. Lloyd has endeavoured to bring completely up to date, although, as he says, the law relating thereto has fallen into considerable confusion. The chemical notes of Mr. R. A. Robinson in the same volume have also been revised and enlarged.

A DIPLOMA IN BACTERIOLOGY.

BACTERIOLOGY is coming to occupy a large place not only in medicine and in public health but in many of the other arts and sciences. This theme formed the text of Sir Frederick Andrewes's address when opening last week the new bacteriological laboratories at Newcastle-upon-Tyne. It is significant that during the same week, at the annual meeting of the Court of the University of Manchester, approval was given to the institution of a special diploma in bacteriology. This is the first diploma in the subject instituted in this country, and the courses of instruction, which candidates will be required to attend before presenting themselves for examination, are designed to supply a thorough training in the general principles of the subject, together with advanced courses in one or more special branches. Graduates in medicine and in science of any approved university may enter for the course, and the syllabus has been designed to meet the requirements of medical graduates who wish to qualify for bacteriological posts, or to obtain a special knowledge of medical bacteriology, and also of graduates in science who desire to take up some branch of bacteriological work. The diploma will be awarded to candidates who have, after graduation in science or in medicine, attended the prescribed courses in the department of bacteriology and preventive medicine, under the general direction of Prof. W. W. C. Topley, over at least one academic year. The course of study comprises (a) courses of instruction in general bacteriology, including the morphology and physiology of bacteria and bacterial classification, the history of bacteriology, quantitative methods of bacteriological investigations, and elementary bacteriological chemistry; (b) special courses of instruction in two or more of the following subjects must also be taken: (1) bacteriological analysis of water, milk, food, &c.; (2) advanced bacteriological chemistry; (3) biometry; (4) parasitism, infection, and resistance; (5) epidemiology; (6) comparative pathology. The examination will consist of written papers on the general subjects

¹ THE LANCET, April 21st. ² Butterworth and Co. 1923. 15s.

and on each of the special subjects selected, together with oral and practical examinations. A thesis to include a report on personal observations carried out in the laboratory must also be submitted. The reason influencing the decision of the University of Manchester to institute a diploma is that the increased importance of bacteriology in human and veterinary medicine, in agriculture, and in other branches of applied science makes it desirable that an adequate course of training should be available for those who wish to undertake bacteriological work of any kind. It is impossible to include in the ordinary medical curriculum more than the rudiments of this subject, and practically no provision is at present made for non-medical students, such as those studying biochemistry and kindred subjects, to whom a knowledge of bacteriological methods would often be of the greatest service. The new diploma may well meet the needs of a number of post-graduate students for whom no adequate provision has hitherto been made.

THE recent list of honours contains the name of Sir Thomas Horder, who becomes a baronet, and of Dr. Gould May, who receives a knighthood. We congratulate the recipients of these honours.

WE regret to announce the death of the veteran surgeon, John Chiene, Emeritus Professor of Surgery in the University of Edinburgh and consulting surgeon to the Edinburgh Royal Infirmary.

THE second part of the Registrar-General's Statistical Review of England and Wales for the year 1921 has now appeared. It will be remembered that in the new annual series a change in format was made from foolscap folio to royal octavo, and the statistical matter was regrouped into medical statistics and civil statistics, each being issued as soon as ready. Part II. of the tables, which now appears, deals with civil statistics (H.M. Stationery Office. 5s.). It contains those tables in the old series with a general demographic interest, along with the numbers of parliamentary and local government electors, recent census populations, and an appendix showing housing conditions and pauperism.

WE have received a copy of the Short History of St. Bartholomew's Hospital, 1123-1923, prepared as a gift-book for the delegates to the 800th anniversary of the hospital which is being celebrated from June 5th to 9th. In this beautiful book, which is beyond praise for its substance and manner, Sir D'Arcy Power deals with the Past and Present, the story being told largely in the language of the original records, and Mr. H. J. Waring with the Future. There are 52 illustrations and plans, several of them in colour. Articles have been incorporated on the Pathological Institute by Sir Frederick Andrewes, and on the Dispensary by Mr. J. L. Moore. The plans for the future have been drawn by Mr. T. A. Lodge. Much help in the preparation has been given by Mr. Geoffrey Keynes, from whom copies can be obtained, on application at the hospital, for 11s., including postage.

FELLOWSHIP OF MEDICINE.—A two weeks' refresher course in general medicine and surgery will be given at the North-East London Post-Graduate College (Prince of Wales's General Hospital), Tottenham, from June 11th to 23rd inclusive. The course will include demonstrations in clinical and laboratory methods with special demonstrations each Saturday at the North-Eastern Fever Hospital and the L.C.C. Mental Hospital respectively. A clinical lecture will be given every day at 4.30 P.M. A course of eight practical lecture-demonstrations on gastro-intestinal diseases of children will be given by Sir William Bayliss, Dr. Bernard Myers, and Mr. E. T. C. Milligan at the "Children's Clinic," Western General Dispensary, from June 11th to July 5th. In addition to other special courses announced last week, Dr. Gustave Monod will give a short course of clinical demonstrations (in English) on practical hydrology at the Thermal Hospital in Vichy, beginning on June 11th. Further particulars from the Secretary to the Fellowship, 1, Wimpole-street, London, W. 1.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

XXII.

THE TREATMENT OF RINGWORM.

THE subject of ringworm may best be dealt with under four headings: 1. Ringworm of the hairy regions, the scalp in children, and the beard region of men. 2. Ringworm of the nails. 3. Ringworm of the glabrous skin of the body and limbs generally. 4. The obstinate form of ringworm known as "Dhobi itch," especially as it affects the hands and feet.

Ringworm of Hairy Regions.

No treatment is efficacious that does not secure the complete shedding of the diseased hair, since no drug at present known is capable of penetrating the hair shaft in sufficient strength to destroy the fungus. Without going into detail as to the cultural varieties of ringworm that affect the hairy regions, it is important to separate two clinical varieties which, owing to their different effects on the skin, need different forms of treatment. The common clinical varieties all produce only a slight degree of inflammation, insufficient to cause shedding of the hair, and are associated with only slight redness, scaling, perhaps a little indolent pustulation and breaking of the hair so that it cannot be extracted with forceps. For these forms it is necessary to use artificial means to cause the hair to loosen and be shed in its entirety from the follicle. Though there are many applications that are capable of doing this in an uncertain proportion of cases, only two, the X rays and the croton oil treatment, may be relied upon in every case.

X Rays.—Where X ray treatment by an expert is obtainable it is the most satisfactory method, being cleanly, painless, regular in its action, and almost completely free from risk, but it cannot be urged too strongly that there is only a small margin of safety between insufficient radiation followed by incomplete fall of the hair and excessive radiation which may cause permanent baldness and even a severe dermatitis. This method should therefore be used only by medical men thoroughly trained in the use of X rays for this purpose. It should also be emphasised that the X rays have no deleterious effect on the fungus and are to be used simply as a means of converting hairy into hairless skin. Consequently during the shedding of the hair and for a period of four weeks afterwards the scalp should be kept constantly under treatment with a fungicide "guard" ointment, the best being, in my hands: *Acidi benzoici*, gr. xxv.; *acidi salicylici*, gr. xv.; *adipis lanæ*, 3ss.; *paraffinum molle*, ad 3i.

Two further points require emphasis. First, I am convinced after bitter experience that when ringworm is once established in the scalp it is wise to depilate the whole scalp by the overlap method of Adamson and not to attempt to treat infected areas only; otherwise the disease may crop up later on in other parts of the scalp and treatment then becomes much more prolonged and difficult. Secondly, it should be remembered that since X rays do not kill ringworm the falling hairs are likely to spread the infection and the patient should therefore be isolated.

Croton Oil.—Should X rays be unobtainable, shedding of the hair may be caused with certainty by means of croton oil treatment. Parents should be warned that this is a painful treatment. In this method one may use either the actual croton oil in very small quantities, painting a single drop over each patch, or one may use somewhat more freely an ointment consisting of one drachm of croton oil in an ounce of lard and rubbing this in gently. The finger used for rubbing in the ointment should be covered with a rubber stall, otherwise there is great risk of causing a whitlow on the finger. This treatment should be

carried out once a day and before rubbing in any fresh oil the parts should be thoroughly bathed with very hot water, any pustules present being opened with a sterile needle and the contents bathed out. After a variable number of days either a severe pustular folliculitis will be produced, or the whole area will swell up into a sort of oedematous cushion. In either case the hair will be so far loosened that it may be drawn entire with its swollen rootsheath. The case must be carefully watched, since if the process is carried too far, the formation of an abscess or sloughing of the skin results. Any appearance of whiteness of the treated skin is the earliest indication of a tendency to slough. In fortunate cases the whole of the affected hair will be shed together, but more frequently a few diseased hairs remain tightly set in the follicle, when each individual hair must be treated separately. A number 16 sewing needle is bent in a spirit flame to an angle of 45° , the angle being placed at a full quarter of an inch from the eye end. The pointed end is set in a needle holder or driven into a stick of soft wood. The eye end is dipped into neat croton oil and the affected follicle is gently catheterised therewith. The oval end of the needle is fine enough to find its way into the follicle, but not sharp enough to pierce the side unless undue pressure is used. The eye performs a useful function in carrying a charge of croton oil which becomes rubbed off as the needle descends into the follicle. The operation demands a considerable degree of skill. During the whole of the croton oil treatment the rest of the head should be kept thoroughly dressed with a "guard" ointment. The treatment is not entirely free from risk of permanent loss of hair, but this never occurs over large areas unless the oil is grossly over-used; on the other hand, it has the disadvantage that needling is almost always necessary to finish the case, and this demands expert skill.

Various Ointments.—Instead of the croton oil application an ointment consisting of equal parts of sodium chloride and vaseline may be used. This is rubbed in thoroughly once a day, after bathing the head with very hot water. The treatment is painful, perhaps even more so than the croton oil, but it is a little less dangerous. It is, however, much less certain to produce the desired fall of hair and sometimes sets up a spreading superficial dermatitis difficult to control and useless in the cure of the disease. Numerous other formulæ have been recommended. Of these, two have given me a reasonable proportion of successes. *Acidi salicylici gr. xlv., ung. hydrargyri nitratis ad ʒi.* rubbed in twice a day and washed out once a week will in favourable cases cause a non-suppurative, painless shedding of the hair resembling alopecia areata; in other cases, unfortunately, it causes a deeply pitting folliculitis and must be given up at once.

The second ointment is a modification of that already mentioned, so increased in strength as to have in some cases a depilating action: *Acidi benzoici, ʒi.; acidi salicylici, ʒss.; adipis lanæ, ʒiv.; paraffinum molle ad ʒi.* This ointment should be rubbed in twice a day; it causes some smarting to the child and may set up a temporary coryza in the person rubbing it in; I have never seen ill-effects from its use, but it is sometimes quite inefficacious.

Kerion Celsi.—The second type of ringworm of the hairy skin is that associated with intense oedematous and suppurative folliculitis, and is generally if not invariably due to the ectothrix fungus derived from domestic animals. It is known in this country as kerion celsi and on the continent as trichophytosis profunda. This type of the disease is self-curative since the inflammation loosens all the affected hair. All that is necessary is to draw these infected hairs from the inflamed follicles and then foment frequently with a solution of mercuric chloride (1 in 4000), keeping the rest of the scalp under a "guard" ointment.

The treatment of ringworm of the beard region is similar to that of the scalp, but the croton oil and sodium chloride treatments should not be used.

Ringworm of the Nails.

This disease is far more common than is generally recognised owing to the difficulty of demonstrating the fungus. Many methods of treatment have been recommended; the following method seems to me infinitely superior to the rest. The patient should be put under a general anæsthetic and all diseased nails gently but entirely removed, particular care being taken to remove any fragments that break off under the posterior nail fold. If, as is commonly the case, the nail bed shows extensive hyperkeratosis this should be gently scraped down with blade of a pair of scissors. After any bleeding has been stopped the whole nail bed should be dressed with *acidi salicylici, gr. xx.; ung. chrysarobini ad ʒi.*, and some of the ointment should be worked as far as possible beneath the posterior nail fold. Pain is not, as a rule, great, but if necessary an opiate should be given for the first night. After-treatment consists in dressing the nail bed daily for at least four weeks with the same ointment. Should any nail relapse the treatment should be repeated, but this is not common.

Ringworm of the Glabrous Skin other than that of the Hands and Feet.

This form offers little difficulty as a rule. If seen early it may be painted with equal parts of tr. iodi and liq. iodi fort., or dressed with the mild benzoic and salicylic ointment given above or with ung. chrysarobini. If the ringworm is of the highly inflammatory kerion variety I think it best to bandage it up with ung. chrysarobini.

Dhobi Itch of the Hands and Feet.

Owing partly to the immense thickness of the horny layer in these situations and partly to the resistant nature of the fungus this form is often desperately refractory to treatment. The nails are often infected and, if so, must be treated thoroughly or relapse is certain. Gloves, socks, and shoes must be disinfected as the fungus certainly resides in the two former and probably in the latter. The bath should also be scrubbed down with a disinfectant; Turkish baths should be avoided. I have had the highest proportion of permanent cures from the following treatment: In the morning after a bath all flaps of frayed horny layer are trimmed away and the roofs of any vesicles removed. The areas of infection are then well rubbed with a cotton-wool swab saturated with 10 per cent. solution of chrysarobin in equal parts of acetone and methylated spirit. This solution dries in a few moments; a pair of cheap cotton socks under the regular socks protects these from the chrysarobin. In the evening as much as possible of the chrysarobin is washed off with soap and water in order to avoid staining the bedclothes, and the 5 per cent. benzoic acid and 3 per cent. salicylic acid ointment is rubbed well in. Next morning this is washed off and the chrysarobin reapplied. This should be continued for four weeks unless chrysarobin erythema supervenes, when the solution must be stopped for a time and the ointment used day and night.

It is advisable in long-standing cases, which are common owing to mistakes of diagnosis, to continue with some alcoholic antiseptic for a long period after apparent cure. The formulæ which have served me best for this purpose are: (1) *Hydrargyri perchloridi, gr. ii.; acidi salicylici, gr. xl.; sp. vini methylati (60 per cent.) ad ʒi.* (2) *Cupri nitratis, gr. xl.; acetone and sp. vini methylati, aa ʒii.*

Adamson has had good results by first painting with 3 per cent. solution of nitrate of silver and then when this has dried immediately painting with tincture of iodine. In my experience this method clears up symptoms quickly but relapse is frequent. Some American writers claim success from the soaking of the feet in a solution of potass. perman. (1 in 2000 to 1 in 500), but I have never been able to establish a lasting cure with this.

ARTHUR WHITFIELD, M.D., F.R.C.P.,
Physician to the Skin Department,
King's College Hospital.

Special Articles.

BRITISH EMPIRE CANCER CAMPAIGN: AN APPEAL.

CANCER, in spite of the advances which have been made both in diagnosis and treatment, is still the most common single cause of death in persons over 30 years of age and is becoming so in an increasing degree. During 1920, in England and Wales, nearly 43,000 persons over 30 and upwards died of cancer. In 1921, the last year for which the Registrar-General's figures are available, the corresponding number was 45,328. During that year, one in every seven deaths from the age of 30 onwards was caused by cancer.

We are still ignorant both of the causation and cure of cancer. Many other diseases have yielded their secrets to patient investigation and there is no reason to suppose that the problem of cancer will not eventually be solved. Yet thousands of suffering men and women, and those who suffer with them, are asking how long they must wait and if there is nothing that can be done to hasten a discovery which will bring relief to those whose outlook is to-day so hopeless.

The answer to this question is clear. The first step towards finding the cure of cancer is to discover its cause. To find that cause no effort must be spared. Every possible line of research must be diligently explored. More men must be set free to devote themselves wholly to research, and their work must not be hampered or prevented by want of money.

Much research work is being carried on and considerable advances have been made in the technique of operations designed to remove the disease in its early stages or retard its progress in more advanced cases. All honour is due to those who have done and are doing the work, but a vast amount still remains to be done. Impressed by the need for immediate action we have joined together to found a movement which will coördinate and support research on cancer throughout the British Empire.

This new concerted movement will be called the British Empire Cancer Campaign. It will be governed and directed by an Executive Council, the members of which will act as chairmen of small working committees each dealing with a separate aspect of the cancer problem.

Medicine, surgery, human pathology, chemistry, physics, radiology, animal and plant pathology, hygiene, and vital statistics will all be represented by committees whose work will be coördinated by the Executive Council acting, in fact, as a central clearing house. The Council is anxious to make it clear from the outset that it has no wish to interfere with the work already being carried out. Individuals and institutions now working on the cancer problem will be helped and encouraged and where practicable financially assisted.

In this way investigation can be carried out simultaneously along many lines and the results of these inquiries will be brought into the common stock of knowledge. A discovery in any one branch will be made known to all, and may lead to discoveries in other branches. It is in this coördination of effort that our most confident hopes are placed.

No one can say with certainty that we shall succeed in our quest to find the cause of cancer, but a movement so broad must inevitably advance the knowledge which we have of this disease and every step forward brings us nearer to our goal.

The British Red Cross Society has placed its organisation and machinery at the disposal of the Council of the Campaign, and a generous donor has already given a sum sufficient to cover the preliminary expenses of this appeal. All future contributions will therefore be expended in encouraging, assisting, organising, and administering systematic research and treatment on a scale that has hitherto been impossible.

To do this a large sum of money will be needed and we appeal with confidence to the British public in the United Kingdom and in the Dominions and Colonies overseas. During the war we had ample evidence of the capacity of this Empire for united and intensive effort, and in no field was it more effectively shown than in the relief of suffering and the prevention of disease. Is it too much to hope that the same spirit will animate our people when they are called upon to wage war against an enemy that is in their very midst? We plead with all earnestness that we may be given the means wherewithal to carry through the task which we have set ourselves to accomplish and thus to bring relief and hope to those whose lives are now darkened by suffering and despair.

The fund will be administered under the direction of a strong Finance Committee. Cheques should be made payable to the British Red Cross Society, crossed "British Empire Cancer Campaign" and sent to the Hon. Sir Arthur Stanley, G.B.E., C.B., 19, Berkeley-street, London, W.1, or to Lloyds Bank, Ltd., 71, Lombard-street, or to any of their branches or agencies at home or abroad.

THE CONSTANTINOPLE BOARD OF HEALTH.

BY F. G. CLEMOW, C.M.G., M.D.,

FORMER BRITISH DELEGATE TO THE BOARD AND PHYSICIAN TO
H.M. EMBASSY, CONSTANTINOPLE.

PART II.*—THE WORK OF THE BOARD.

THE work done by the Constantinople Board of Health may best be understood by grouping it under three main headings: (1) the Mediterranean and Black Sea sanitary service; (2) the Red Sea sanitary service, the Mecca Pilgrimage, and the Hedjaz Railway; (3) the Turco-Persian Frontier sanitary service and the Shiah pilgrimage and transport of dead bodies. This division of the work was indeed formally recognised, both administratively and financially, almost from the first; and in the Board's balance-sheets the receipts and expenditure of each of the three "services" were, till the end, set forth separately. The ideal aimed at was that each "service" should, as far as possible, be independent and financially self-supporting; and in the earlier years the finances of the three were not only kept separately, but it was even laid down that a deficit in one was not to be covered by a surplus in either of the others, but was to be borne by the Turkish Government. In later decades, however, the "fusion" of the three services was formally admitted, and though the figures for each continued to appear separately, the totals were added together and a deficit or surplus established in the Turkish sanitary service as a whole.

In each of the three services the Board administered a series of lazarets, disinfecting stations, and sanitary offices. The latter existed at practically every port of any size around the coasts of the Turkish Empire and at suitable places along the land frontiers. The maritime offices were charged with the interrogation of ships, the examination of bills of health, the collection of sanitary dues, the granting of sanitary visás, and the reporting to the central administration of any event of sanitary importance,

* Part I. was published in THE LANCET of May 26th, p. 1074.

such as the occurrence of plague or cholera on a ship or the outbreak of infectious disease in the port or its neighbourhood. In like manner the lazarets and disinfecting stations were placed at suitable intervals along the coasts or on the frontiers.

The Mediterranean and Black Sea Sanitary Service.

There were five lazarets, of different size, in this service—those of Sinope, on the northern shores of Asia Minor; Kavak (or Monastyr-Aghzi), near the northern end of the Bosphorus; Touzla, on the Sea of Marmora; Clazomene, near to Smyrna; and Beirût, on the Syrian coast. In addition there were small disinfecting stations, well furnished with steam stoves, at Jaffa and Rhodes. Of these only the first four now remain to Turkey. In former years there was something in the nature of a lazaret at Nagara, on the Dardanelles, but for many decades it had practically ceased to exist. It will be observed that, while the coasts of Asia Minor, Syria, Palestine, and the Straits (Bosphorus, Sea of Marmora, and Dardanelles) were sufficiently well supplied with lazarets and disinfecting stations, there were none on the shores of European Turkey—either on the Ægean or Adriatic side—nor on those of African Turkey (Tripoli and the Cyrenaica).

The lazaret of Sinope was intended for the reception of pilgrim ships or other large ships subject to measures coming from any port in the Black Sea, and destined for Constantinople or any port south of the Straits. It was a large and straggling establishment, but possessed a good modern disinfecting block, provided with three stoves. When visited in 1908 the rest of the buildings were in bad condition; during the war it was occupied by Turkish troops and this has, I understand, all but completed its ruin. It was formerly capable of lodging about 1200 persons in quarantine.

The lazaret of Kavak was intended to be only a secondary establishment, a sort of "succursale" of Sinope. It has a fairly good disinfecting pavilion, but can only lodge some 250 persons at a time. The question of transferring this lazaret to a better site in the Bosphorus, where a large one could be built to replace the two lazarets of Sinope and Kavak and deal with all arrivals from the north, has for some time been under consideration. The protection of the "Straits" by means of such an establishment or by other means is, indeed, of primary importance to the other countries of Europe. The Straits and the Suez Canal constitute two great waterways by which Europe is constantly threatened with the introduction of epidemic diseases from the East. In the past the majority of ships from the Black Sea subject to measures, and especially of pilgrim ships, came from the Russian ports of that sea. In later decades they brought large numbers of passengers and pilgrims not only from all parts of Russia—including European Russia, the Caucasus, Central Asia, and Siberia—but also from other Asiatic countries. The development of railways in these regions led to a vast increase in the movement of pilgrims and traders by this route of the Black Sea and the Straits. In European Russia there was a fairly complete network of railways; these were linked up with the Trans-Siberian and Transcaspiian lines. The latter had extensions to Samarkand, and the provinces of Semipalatinsk, Semiretchinsk, and Ferghana. On the west of the Caspian it was continued in the Transcaucasian railway from Baku to Batoum, with an important branch from Tiflis to Julfa and Tabriz in Persia. Already these lines are linked directly or indirectly with the Bagdad railway, the Hedjaz railway, and the lines of Asia Minor. If the movement on these various routes was great in the past, it will unquestionably be still greater in future.

The Touzla lazaret, situated on the Gulf of Ismid (Sea of Marmora), is a small establishment, and should perhaps be grouped with the disinfecting stations rather than with the lazarets. It has an excellent disinfecting pavilion, a small hospital and laboratory,

but no houses for lodging persons subject to detention in quarantine.

The Clazomene lazaret, on the island of that name in the Gulf of Smyrna, was a fairly large and good lazaret, possessing a good disinfecting block, hospitals, and houses for lodging some 2000 persons at a time. It is reported to have suffered much damage during the war.

Finally, identical statements may be made in regard to the Beirût lazaret, save that here there was accommodation for some 1500 persons only. The two disinfecting stations of Jaffa and Rhodes were each provided with a quite excellent disinfecting pavilion, but with nothing else. To complete this brief sketch of the Mediterranean and Black Sea sanitary service, it must be added that there were as many as 84 sanitary offices, "principal" and "sub-ordinate," in different Turkish ports; of these only 31 were on territory that now remains Turkish.

In a concluding article the financial arrangement of the Board and the sanitary organisation for the future will be considered.

(To be concluded.)

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Early Treatment of Œsophageal Injuries by Bougie.

In a paper recently read before the Vienna Medical Society Dr. Salzer discussed the best methods of treating the condition, frequently found in children, of Œsophageal strictures produced by swallowing caustic substances. Three years ago he had reported to the same society that his routine treatment was to apply a bougie very early after the injury, and he had then shown a dozen cases. He had since had 24 more cases of such injuries under observation. He used to apply a bougie as soon as the acute symptoms had subsided—i.e., on the third to sixth day after the injury—not, as had hitherto been customary, after a few weeks, when cicatricial stenosis was already well established. Of the 24 cases newly reported 21 were cured and 2 died before treatment could be commenced; one boy, aged 3 years, died on the seventh day after four treatments, post-mortem examination revealing pneumonia, but no perforation of Œsophagus or stomach. Thus, out of 37 cases observed, 33 were cured, and 1 died during treatment, but not owing to it. In Hungary, Dr. Bokag and Dr. Erdelyi had treated 116 children on the same principle, with excellent results. Only 5 died, but not directly owing to the treatment. In adults the same principle of very early application of a bougie had also been used in the Vienna surgical clinics; the four cases seen were all cured. Dr. Salzer strongly urged practitioners to resort very early to this safe and trustworthy method.

New Professor of Pathological Anatomy at Vienna.

The chair of pathological anatomy in the University of Vienna, which has been vacant for half a year, has now been filled by the appointment of Prof. R. Maresch, who is a pupil of Paltauf, and has held, amongst other posts, that of prosecutor of the City of Vienna Hospital. Prof. Maresch has a wide reputation as a teacher and research worker, his main interests being bacteriology and tumours; he will take up his duties during the summer.

Treatment of Severe Hæmorrhage by Blood Transfusion.

Prof. Victor Blum recently showed to the Surgical Society of Vienna a patient, aged 65, who had suffered from prostatic hypertrophy. He had been passing about 6 litres (about 12 pints) of urine per day, and had suffered from severe thirst; a diagnosis of diabetes had been made elsewhere, and treatment instituted accordingly. Only after some time had elapsed was the condition properly diagnosed as severe insufficiency of the kidneys, over-distension of the bladder, and prostatic hypertrophy. Operation

consisted in suprapubic prostatectomy after slow evacuation of the bladder. Severe hæmorrhage gave much trouble, but was twice controlled; on the thirteenth day blood again appeared in the urine, in such profusion that the patient became quite pulseless. All known methods of stopping the hæmorrhage were tried, and finally resort was had to blood transfusion by means of the Ohleckers apparatus. The patient's son served as donor, 750 c.cm. being transfused with excellent results. The pulse returned, the patient rapidly regained normal colour, and the bleeding stopped at once. Except for a severe rigor after half an hour, with a sudden rise of temperature, the patient made an uninterrupted recovery, and is now practically cured of all his troubles. Prof. Blum strongly advocates the use of transfusion for all cases of severe bleeding in surgical and non-surgical cases, and points out that whilst in Central Europe this method is not much used, it is quite common in the United States, especially as a preparatory measure for prostatectomy in weak cachectic old men with renal insufficiency, in cases of anæmia due to acute nephritis, and in treatment of urosepsis and of puerperal sepsis. In the discussion following the demonstration, Prof. A. Eiselsberg, in whose clinic the apparatus is working, offered its use to any member of the profession requiring it, together with the help of trained men capable of handling the rather intricate mechanism.

Statistics of Population in Leading European States.

An interesting review of problems of population was recently published by the Austrian Statistical Board. From the figures given the population of the chief western countries at the beginning of the nineteenth century was as follows: France (comprising about the same territory as at present) 27 millions; England, about 16 millions; Germany, about 22 millions; Italy, 18 millions. After the Napoleonic wars—i.e., in 1816—France had a population of 29½ millions and Germany 25 millions. Fifteen years later France was left behind with 36·8 against Germany's 42·7 millions. In 1913 the proportion was Germany 67, France 39·8 millions. At present Germany, although she has lost, by the terms of the Peace Treaty, over seven millions of German-speaking people, is already making up the loss; France, in spite of having regained Alsace-Lorraine, has to-day only 39½ millions. Comparison of the populations of Britain and France shows that in 1801 France was 60 per cent. ahead; in 1881 the figures were: the United Kingdom 35 millions, France 37 millions; and in 1922 the United Kingdom had 48 millions, France 39½ millions. Comparing the populations of France and Italy, we find that in 1801 France had 50 per cent. and in 1891 25 per cent. more population than Italy, and still led by 12 per cent. in 1913; but in 1922 Italy had passed the 39th million, and in a few years' time, with her much quicker rate of increase, she will leave France behind. From the figures quoted it must be inferred that the natural increase of the French nation has been restricted for at least a century.

Epidemic of Measles in Vienna.

The statistics of the Vienna Board of Health show that there is a recurrence of measles, in epidemic form, every three years in the city. Acting on this knowledge, the authorities have already made arrangements to meet this year's expected demand for hospital beds for infectious cases. Measles is not notifiable in Vienna, and very often no medical help is summoned to a case; thus infection in the schools goes unchecked, as when a child is ill its brothers and sisters frequently continue to attend. The Board of Health has notified the public that the increase of measles is a regular occurrence, giving no cause for undue alarm.

Increase of Cocainism.

Cocainism has spread to such an extent in Vienna that the authorities have had to institute stringent repressive measures. Apart from action against illicit traffic in the drug, the police have ordered that

persons found to be addicted to the habit shall be detained and, if possible, be sent to hospital. Apothecaries and druggists are instructed to refuse to dispense cocaine in powdered form, only solutions being now permitted. Each prescription containing cocaine must bear the instruction "no repetition." Two recent suicides of well-known persons addicted to the habit have aroused considerable discussion in the city.

May 17th.

ROUMANIA.

(FROM OUR OWN CORRESPONDENT.)

Spread of Typhoid Infection by the Hands.

Dr. Schmidt, of Marosvasarhely (Transylvania), in a recent lecture on the different ways in which typhoid infection is conveyed, stated that in his opinion the dangers of impure water had been greatly exaggerated. He suggests that the principal means of infection is the hands of patients recently recovered from the disease—bacillary carriers who still have bacilli in their stools. Unless the hands are washed after each defæcation they are liable to deposit the organisms on everything they touch, and patients whose daily work necessitates the handling of foodstuffs thus do great harm. Dr. Schmidt urged the establishment of control stations for convalescents in the large towns of Transylvania, where 1000 to 1200 persons die of typhoid yearly. He also advised the display of explanatory circulars in public places and the giving of dictation exercises on the subject in the schools, as was done some years ago in France.

Leprosy in Herzegovina.

Dr. Vokurka, who has lately returned from a study of leprosy in Herzegovina (Jugo-Slavia) found the disease to be very sparingly distributed over the latter country and over Bosnia, both of which countries formed, before the war, parts of the Austro-Hungarian monarchy. Dr. Vokurka surmises that it was probably a new disease when first recognised in Serajevo some 150 years ago, since which time it has gradually extended over the whole country. The principal point of interest in these observations is the confirmation which Dr. Vokurka has found of his theory that leprosy is due to deficient alimentation—in this instance to the consumption of badly-cured mutton. This finding is in harmony with that of the late Jonathan Hutchinson, who traced leprosy in South Africa to the consumption of badly-cured salt fish. Dr. Vokurka considers, however, that the evidence is in favour of the disease being sometimes communicated from man to man, not by direct contagion, but by the consumption of food handled and contaminated by leprosy persons. As this method of transmission is possible only under circumstances of the grossest hygienic neglect, the incidence mainly among the poorer classes is explained. Dr. Vokurka favours legislative control of the sale of food, education of the public as to the methods of transmission, and establishment of leper homes for use by victims of the disease during the infectious period.

The Spread of Venereal Diseases.

The prevalence of venereal diseases per 1000 men in the Transylvanian army (eastern group of the Roumanian army) was 73·6 in 1921 and 61·0 in 1922. The incidence of syphilis is decreasing, owing to the fact that since 1920 soldiers have been examined every week by venereal specialists; if any disease is found the man is sent to a special hospital until radically cured. Those suffering from syphilis are summoned every three months to undergo a course of treatment during the first year afterwards; and during the next two years they are summoned to undergo a blood test every six months. If in the meantime the soldier returns to civilian life, he is registered by the parish medical officer and must present himself at the nearest venereal hospital for a blood test every six months.

May 14th.

UNIVERSITY OF DURHAM COLLEGE OF MEDICINE, NEWCASTLE-UPON-TYNE. OPENING OF NEW BACTERIOLOGICAL LABORATORIES.

NEW laboratories built by the College of Medicine to accommodate the department of bacteriology were opened by Sir Frederick Andrewes, F.R.S., professor of pathology in the University of London, on May 25th. There was a large attendance, composed partly of members of the profession residing in Newcastle and the neighbouring counties, but including, also, many men prominent in the affairs of the district, as well as the principal and heads of departments of Armstrong College, and the President, staff, and students of the College of Medicine. The guests were received in the King's Hall of Armstrong College by Sir David Drummond, President of the College of Medicine, and after tea the company adjourned to the physics theatre to hear the addresses. When Sir Frederick Andrewes had completed his address, Sir David Drummond presented him with a key suitably inscribed, and asked him to open the building.

History of the New Department.

Sir David Drummond, after offering a hearty welcome to Sir Frederick Andrewes and the guests, explained why a new building was found to be necessary, and why it had been erected upon a site in connexion with Armstrong College rather than upon the site at present occupied by the College of Medicine. Accommodation in the latter had fallen short of the requirements, especially in so far as the more technical and practical sections of the curriculum were concerned, and the pressure had been felt most acutely in the department of bacteriology. The council of their sister college, Armstrong College, had made the liberal and magnanimous offer of a site adjacent to the agricultural department, and further offered to advance the capital necessary for the erection of the building, stipulating only that they should be consulted as to the design and structure of the building so that it might readily be converted to other needs when the College of Medicine found themselves able to erect their new college upon the site recently acquired next to Armstrong College. This generous offer had been accepted by the Council of the College of Medicine with thankfulness. The University of Durham and the City of Newcastle-upon-Tyne had thus acquired a most important educational development in the shape of what he ventured to hope Sir Frederick Andrewes would find to be one of the best bacteriological departments in the country.

The Place of Bacteriology in the Arts and Sciences of the Present Day.

Sir Frederick Andrewes spoke of the place which the science of bacteriology had now come to occupy, not only in medicine and in public health, but in many of the other arts and sciences. He outlined the history and development of bacteriology from the time when the great Dutchman, Leeuwenhoek, often spoken of as the "father of microscopy," first distinctly saw the organisms which we now know as bacteria. This was nearly 250 years ago, and to Leeuwenhoek, and, indeed, to his successors for more than 150 years, they remained merely objects of interest and wonder. It was not until the rise of chemistry that the nature of fermentation could be understood, and then the microscope revealed that the mysterious substance which, when added to the fermentable material, initiated the chemical changes, owed its power to the presence of micro-organisms. An even more important impulse was given by the discovery of the relation of micro-organisms to infective disease. The things that kill a man touch him more closely than the cheese he eats or the beer he drinks. As early as 835 a silk-worm disease known as "muscardin" was found by Bassi to be due to a fungus, and in the following decade the parasites of favus and ringworm

were discovered. The first bacterial disease to be identified was anthrax. The infecting agent was seen in the blood of infected animals by Pollender in 1849, and by Davaine in 1850.

Of all the great names which stood out in the nineteenth century that of Pasteur must take the first place in connexion with bacteriology. It was a happy omen that these new laboratories should be opened in the very week when the 100th anniversary of that great investigator's birth was being celebrated. For his chief claim to immortality was not that he was a great chemist—as he was—but that he founded a new science. Pasteur transformed bacteriology into an experimental science. He was the first to cultivate bacteria artificially and to bring them into the domain of the laboratory. The second great name in bacteriological science was that of Robert Koch, who devised the means of culture on solid media and enabled us to make certain of the purity of our growths. No difficulties seemed too great for this man to overcome, as was well shown by his discovery of the cause of tubercle.

After sketching the development of bacteriology on the medical side, Sir Frederick Andrewes pointed out that the greatest service which the bacteriologist had rendered was in focusing attention on the human carrier of infection. We now knew that many human beings might become so far immune as to be capable of harbouring and, what was worse, of disseminating the infecting agents of certain diseases.

But in spite of the attention which their importance had attracted, probably not one in a hundred of the existing species of bacteria had any relation to disease. In many industries it had proved possible to utilise the chemical powers of bacteria. Nature had been found to work more economically than art, and the chemistry of these minute organisms was more subtle than that which the laboratory could accomplish. The manufacture of lactic acid and acetone were examples. It was in agriculture and allied industries that some of the most important applications of bacteriology were to be found. In the front rank stood the discoveries of the nitrogen-fixing powers of certain bacteria, especially well seen in the root nodules of leguminous plants, whereby the importance of these in the rotation of crops received a rational explanation. Milk was a particularly favourable medium for the growth of bacteria, so that the whole dairy industry was deeply concerned in questions of bacteriology. Bacteriology was, in fact, a subject of high industrial importance, fully worthy of careful study even if it had no application to medicine.

Sir Frederick Andrewes concluded with a word on the teaching of bacteriology. He said: "It must be taught in two stages. First must come the academic study of its general principles. For this purpose the situation of the laboratories opened to-day seems admirably adapted, and the University may congratulate itself on such provision for the teaching of the subject. The second stage of teaching can only be carried out effectively in relation to the special arts and sciences to which bacteriology may be applied. It would, I think, be a misfortune if the establishment of the central teaching of bacteriology in this institution led to any divorce from medicine, and I trust it may have the contrary effect. The medical aspects of bacteriology can only be studied to advantage in close relation with medicine itself."

The Building and Equipment.

The new laboratories are situated on high ground to the north of the city, adjoining the department of agriculture of Armstrong College. The building comprises 3712 superficial feet, occupies two main floors, with a basement below and accommodation for animals on the roof. Ventilation is effected on the exhaust system, the stale air being extracted by an electric fan, while fresh air is admitted through inlets placed behind the radiators as well as through Sheringham valves at a height of 5 feet 6 inches from the floors. The building is heated by steam on the atmospheric principle. On one side of the hall is a

chemical laboratory, and on the other an office of similar size. The rear part of the ground floor is occupied mainly by a laboratory, 47 ft. by 24 ft. by 14 ft., affording accommodation for about 50 students. On this floor also are three small laboratories and a dark room for photography. Around the first floor landing are arranged five laboratories; one, measuring 34 ft. by 22 ft. by 15 ft., is for sterilisation and preparation of culture media, with a staircase giving access to the animal rooms above. The working benches are made of pitch pine, covered with linoleum, while incubators and water-baths stand on tables covered with asbestos sheets. In place of the usual porcelain sinks a lead-lined trough, coated with bitumen, runs the whole length of the back of the benches. The animal houses open on to a flat asphalt roof, from which an outside lift runs to the ground level, thus avoiding the necessity of carrying dusty materials through the building. The architects are Messrs. Knowles, Oliver and Leeson, of Newcastle.

CONGRESS OF THE ROYAL INSTITUTE OF PUBLIC HEALTH.

(Concluded from p. 1078.)

FRIDAY, MAY 18TH.

ON the second day attention was given to venereal diseases. In the State Medicine Section this subject was ably dealt with by Colonel L. W. Harrison, who described the clinic at St. Thomas's Hospital by means of a model. He emphasised the fact that many of the clinics are not yet efficient, and that while this is so, it is no good talking about notification. He also stressed the fact that we are now in a position to abolish congenital syphilis by the treatment of the expectant mother, if the various departments would all work together. In the Women and the Public Health Section notification was discussed, the Canadian system of notification was mentioned, and the need for providing treatment at ante-natal clinics for venereal diseases.

Mr. S. Fisk dealt with the prophylactic treatment of dental caries.

A vigorous discussion took place on the small-pox and vaccination question, opened by Dr. C. Killick Millard. Dr. Millard pointed out that small-pox had lately become a much milder disease, in spite of the neglect of vaccination, and that we are now in a position to deal with outbreaks much more efficiently than formerly. He urged that the damage done by wholesale vaccination was now more than that done by small-pox itself; he advocated an alteration of the vaccination laws and faith in emergency vaccination. Most of the speakers in the discussion opposed these views.

In dealing with the question of vocational unfitness Mr. Cyril Burt, D.Sc., pointed out that a considerable proportion of juvenile delinquency is due to the fact that the delinquents are set to work for which they are not suited. The work may operate harmfully by making too little or too great a demand on the intelligence of the worker.

MONDAY, MAY 21ST.

On the resumption of work by the sections on Whit Monday great interest was taken in the discussion on birth control. Mrs. Mary Scharlieb strongly opposed artificial methods. Mrs. Hodson, of the Eugenics Education Society, put forward the plea that carefully used birth control had become necessary to prevent the propagation of the unfit. We had taken upon ourselves as a community to prevent natural selection and had made ourselves responsible for putting something in its place. Dr. N. Macfadyen, of Letchworth, pleaded for the impartial consideration of the whole matter by the medical profession. Mr. H. V. Roe, of the Society for Constructive Birth Control, mentioned the report by the General Federation of

Trade Unions on the excessive sickness in Dundee, in which were instanced many cases of excessive child-bearing. For example, 11 women had given birth to 78 children, and these had a death-rate of 62 per cent. Many of the audience must have come to the conclusion that intelligent methods of birth control have no place in a scheme for preventing the propagation of the unfit, but that for such a purpose the choice lies between sterilisation and segregation for life.

In the State Medicine Section Dr. H. P. Newsholme opened a discussion on Diet Deficiencies in Relation to Public Health, giving a useful survey of the subject. He pointed out that many of the recent changes in our food were due to urbanisation and the necessity for having food that is transportable and will keep. We cannot, therefore, go back to the old style, but we can compensate and correct for what the new knowledge shows to be errors. Dr. H. Scurfield, after mentioning that the vitamin research confirmed the wisdom of our forefathers in valuing milk, green vegetables, and fruit, said he had been much struck by the way the knowledge of vitamins was being adapted for poultry-rearing.

Dr. J. R. Kerr, of St. Helens, in an interesting paper on the American Industrial Doctor, outlined the progress in the provision of medical and surgical care for employees in America during the last half century, and showed that the Pilkington Special Hospital of St. Helens was doing this work on a large scale.

Mention must be made of a few of the interesting papers read before the Section for the Navy, Army, Air Force, and Tropical Diseases. Sir Leonard Rogers called attention to the intimate relationship between leprosy and rainfall. He emphasised the importance of segregation in self-supporting colonies, and concluded with some suggestive remarks on the treatment of the disease. Dr. W. A. Lethem, in a most interesting paper, produced evidence to show that the spread of bubonic plague among persons in the same house in this country was probably through the medium of *Pulex irritans*, and he contended that disinfection in such cases was of even greater importance than rat destruction. The question of malaria was discussed in communications from Prof. J. W. W. Stephens and Lieut.-Colonel C. W. Holden, R.A.M.C., the former dealing with the treatment of the cases in England, and the latter with the prevention of the disease in the field. The two papers were taken together and gave rise to an interesting discussion on the place of quinine and other drugs in treatment and prophylaxis. Wing-Commander H. E. Whittingham and Flight-Lieut. A. F. Rook described their work on the prevention of phlebotomus fever in Malta. The life-cycle of *P. papatacii* was shown in a series of diagrams and exceptionally beautiful microscopic specimens. The various methods of protection, treatment of buildings and roads, nets, cresol sprays, and fans, were dealt with and their efficacy demonstrated by statistics. The pathology and treatment of various forms of gas poisoning in war was the subject of a communication from Surgeon-Commander Gerald R. McCowen. Major A. T. Frost, R.A.M.C., read a paper on the interaction between syphilis and the ductless glands. He discussed the rationale of potassium iodide in this disease and quoted very encouraging results from the exhibition of thyroid extract in preventing relapse.

UNIVERSITY OF PARIS.—A "cours de perfectionnement" on Recent Ideas concerning Diseases of the Liver, Bile-ducts, and Pancreas, and Diabetes, will be held from July 2nd to 13th in the Amphithéâtre Trousseau, Clinique Médicale de l'Hôtel Dieu. The course will comprise 32 lectures, and will be under the direction of Prof. Maurice Villaret, who will be assisted by Drs. Okinczyk, A. Baudouin, Herscher, Chabrol, Lippmann, Jomier, Brin, Saint Girons, Coury, Benard, Dumont, Deval, Tissier, and P. Descomps. Fee for the course, Fr.150. Foreign medical men and students in the Faculty of Medicine of the University will be admitted. Further information may be had on application to the Secretariat of the Faculty (Guichet No. 3).

Correspondence.

"Audi alteram partem."

THE CAUSE OF DEATH IN ANGINA PECTORIS.

To the Editor of THE LANCET.

SIR,—I cannot leave the very courteous letter of Dr. Walter Verdon, in your issue of May 26th, unacknowledged. But I have no objection to make to the substance of Dr. Verdon's arguments. It seems to me convenient to confine the name angina pectoris to cases of organic disease, and to classify the functional cases with their different phenomena and issues under some other name, or some qualification of the name. I have remarked in my book on arterial diseases, as Dr. Verdon says, how often in cases of true angina death occurs in the slightest seizures. In these cases the heart is very degenerate, but the severer pains seem to arouse more systemic resistance.

I am, Sir, yours faithfully,

Cambridge, May 26th, 1923.

CLIFFORD ALBUTT.

THE CLAIMS OF NON-PANEL PRACTITIONERS.

To the Editor of THE LANCET.

SIR,—In view of the probable alteration of the Insurance Act this year, I should like to bring forward the claims of two classes: (1) Those members of the medical profession who held to their word at the time of the agitation in 1911, and (2) those members of the public who prefer to pay for their attendance privately, although also compelled to pay panel contributions. The promise of the author of the Act was that such patients should have full choice of doctors, even if they were not on the panel, and patients who wished to choose such doctors could do so under the contracting-out clause with its pooling scheme. However, by the action of the local insurance committees these conditions have been rendered a dead-letter. Would it not be a simple act of justice to have these wrongs remedied in the impending changes?

Practising as I do in a town of industrial people, I have felt that the numerous patients who still hold to me, in spite of being allotted a panel doctor, are worthy of consideration, and that to them contracting-out on reasonable terms should be allowed without unnecessary restrictions in the way of forms and files. I can see no reason why panel doctors should object to this if they recall that the non-panel men still stand where they once stood before the débâcle.

I am, Sir, yours faithfully,

RAYMOND H. SHAW, M.S., M.B.,

May 25th, 1923. Senior Surgeon, Great Yarmouth Hospital.

A TREATMENT FOR TAPEWORM.

To the Editor of THE LANCET.

SIR,—With reference to the article on the Treatment of Intestinal Worms in your issue of April 14th, I desire to draw attention to a treatment for tapeworm which will, I think, be found on trial to give consistently satisfactory results.

Some years ago the writer was called upon to treat a case of very intractable tapeworm (*saginata*) infection, which had existed for over a year, and had survived three vigorous treatments with freshly prepared emulsion of ethereal extract of male fern, in addition to one with pelletierine tannate, the whole worm on each occasion, with the exception of the head, having been evacuated en bloc. On consideration it seemed to me that in such cases, after the expulsion of the bulk of the worm with male fern, instead of the usual policy of wait-and-see, additional measures should at once be instituted with a view to inhibit the growth of further segments from the retained head. Accordingly, immediately after a fourth treatment with male fern which, as before, removed all the worm with the exception of the head,

15 gr. of beta-naphthol in tabloid form were administered to the patient each morning, for ten consecutive mornings, on an empty stomach along with a cup of tea, no food being allowed until lunch time. The result was altogether satisfactory, no trace of the worm ever after being seen.

This treatment has been tested both by myself and others in many subsequent cases, and in no instance has it been known to fail.—I am, Sir, yours faithfully,

JOHN W. TOMB, M.D., D.P.H.

Mines Board of Health, Asansol, Bengal, India, May 10th.

THE LANGUAGE OF MEDICINE.

To the Editor of THE LANCET.

SIR,—The reform of the English in which much medical literature is written would be a task of terrifying magnitude, involving, as it would, nothing less than the reform of the writers, but I should like to enter a protest against one common offence, the employment of hybrid compound words, such as "peri-aqueductal" and "hypo-somnia." What would be thought of the education of a writer who dealt in such impossible barbarisms as "Tête-Schmerz" or "Doppel-entendre"? Yet it is only general ignorance that makes the former more tolerable than the latter. If it is beyond our power to express our meaning with the assistance of Greek or Latin without employing impossible compounds, why should we not make a serious effort to say what we have to say in English? The language possesses a splendid vocabulary and an august literature, and the moderate labour involved in writing in a manner worthy of both these great possessions would result in making our medical journals much better reading, and would be of very real benefit to the writers.

I am, Sir, yours faithfully,

East Grinstead, May 21st, 1923.

F. C. POYNDER.

DIETETIC TREATMENT AFTER GASTRO-ENTEROSTOMY.

To the Editor of THE LANCET.

SIR,—I was much interested in reading in THE LANCET of March 31st (received yesterday) Sir Berkeley Moynihan's interesting address on the treatment of duodenal ulcer, in which he sets out the menu which he gives to all his gastric and duodenal cases after operation. In this he mentions "meat cooked a second time," "boiled milk," and "the teeth and gums and the inside of the cheeks should be brushed with care two or three times daily."

As to the first, I prefer meat once "cooked to a turn"—i.e., juicy tender flesh which dissolves in the mouth during mastication. I consider over-cooked meat—all the sap remaining in the oven—on a par with cooked timber, absolutely useless as a food; and after long experience in this land of meat-eating I have been forced to the conclusion that it acts as a foreign body and as such is a fertile source of cancer of the stomach. In reference to the second, I happen to be a believer in the dictum "boil milk and you spoil milk," and consequently I order fresh milk when it can be obtained from a healthy cow; but if any doubt should exist as to the latter I recommend scalding, always with primary scalding of the vessel in which it is about to be retained. In many adults there seems to be an extraordinary repugnance to milk, which boiling intensifies, a dislike which I can only explain by the difficulty they find in digesting it. This may be ameliorated by the addition of barley- or mineral-water, and a few grains of citrate of soda. In suitable cases a teaspoonful of whisky to each glass of milk is a helpful combination. I never permit milk to be taken with a meat meal—for which (dinner) champagne is my nomination.

As to the last-quoted item—"brushing of teeth, gums, and cheeks"—I have no experience of brushing the two latter, but have had an extended one in the brushing of teeth. Rightly or wrongly, I have come to the conclusion that a large percentage of human woe—

e.g., pyorrhoea, dental caries, gastric pollution, appendicitis, and organic decomposition in general—is caused by the inane daily scrubbing of teeth with bristles and by the insane use of chemical dentifrices, both of which lacerate and mortify living tissue, destroy epithelial defence, and provide the entrance for hostile germs. I earnestly invite attention to the handicap this kind of thing imposes on the natural disinfectants—saliva and mucus. I do not believe that there is a human being to be found outside a mad-house who advocates similar brushing of the interior of the anal canal. If such a hygienic enthusiast can be discovered I am prepared to lay him odds that in nine cases out of ten the immediate result will be proctitis plus toxæmia, and that the ultimate one will be cancer.

In ventilating this opinion I do not wish it to be inferred that I disapprove of cleansing the teeth at bedtime. On the contrary, gentle rubbing with a soft (badger hair) brush and some ordinary soda or other effervescent potable water is an unirritating and salutary procedure, and I can personally vouch as to its being an effective and agreeable one. But as to disinfection of the gums and buccal mucous membrane the job appertains to the natural scavengers, and any artificial meddling with their work is as insensate as it is destructive. In other words, do not put anything into your mouth that you would be ashamed to put into your stomach.

I am, Sir, yours faithfully,

JOHN O'CONOR, K.B.E., M.D.

Buenos Aires, April 25th, 1923.

The Services.

ROYAL HOSPITAL, CHELSEA.

Maj.-Gen. H. C. Sutton to be Lt.-Gov. and Sec., vice Maj.-Gen. W. D. Bird.

ROYAL ARMY MEDICAL CORPS.

Capt. A. G. G. Thompson retires, receiving a gratuity, and is granted the rank of Maj.

Temp. Capt. V. J. A. Wilson relinquishes his commn., and retains the rank of Capt.

Temp. Capt. E. K. Campbell relinquishes the actg. rank of Maj.

Temp. Lt. R. W. Shaw to be temp. Capt.

ARMY RESERVE OF OFFICERS.

Col. N. Faichnie, late R.A.M.C., having attained the age limit of liability to recall, ceases to belong to the Res. of Off.

Lt.-Col. G. S. Crawford, having attained the age limit of liability to recall, ceases to belong to the Res. of Off.

TERRITORIAL ARMY.

General List: Maj. E. R. Lovell (late R.A.M.C., S.R.) to be Capt., and relinquishes the rank of Maj.; A. H. Richardson (late Surg. Lt. Royal Navy) to be Lt. Capt. H. Wade relinquishes his commn., and is granted the rank of Col.

General Hospitals: Lt.-Col. (Bt. Col.) A. B. Gemmel, having attained the age limit, is retired and retains his rank; Maj. G. R. Murray, having attained the age limit is retired, and retains the rank of Maj.; Capt. A. W. Harrington and G. Wright relinquish their commns. and retain the rank of Capt.

Capt S. D. Reid to be Div. Adj., 14th (II. Counties) Div., T.A., vice Capt. J. Higgins, vacated.

INDIAN MEDICAL SERVICE.

Lt.-Col. A. A. Gibbs to be Col.

Chuni Lal Katial and Ram Chand Goulatia to be temp. Lts.

The King has approved the grant of the rank of Capt. on retirement to the undermentioned: Braj Bushan Kapila, Gauri Shankar Bhargava, and Girija Sankar Chatarji.

ROYAL AIR FORCE.

The undermentioned are granted short service commissions in the ranks stated: E. D. D. Dickson (Flight Lieutenant) and J. B. Gregor (Flying Officer).

H. H. R. Bayley is granted a temporary commission as Flight Lt.

Flight Lt. C. S. Dowdell relinquishes his temporary commission on ceasing to be employed.

Obituary.

VAUGHAN HARLEY, M.D. EDIN.,
M.R.C.P. LOND., F.C.S.

Edward Vaughan Berkeley Harley, who died suddenly on May 21st at the age of 59 years, was the son of the late Dr. George Harley, F.R.S. He studied medicine at Edinburgh University, obtaining the bronze medal in pathology, and graduated M.D. with honours in 1886, being awarded the gold medal for the best thesis. The next two years were spent travelling round the world, during which period he had the opportunity of working with the late Sir Patrick Manson. The succeeding four years were occupied in scientific study in Paris (under Profs. Pasteur and Roux), Leipzig (under Prof. Ludwig), Vienna, Buda Pesth, Turin (under Prof. Mosso), and Christiania. In 1893 Harley was invited by the late Sir Victor Horsley to return to London to organise the first department of pathological chemistry in England, in the pathological department of University College, London, and this became a centre of research for post-graduate students. In 1894 he was appointed Grocer Research Student. When Horsley retired in 1896 Harley was appointed professor of pathological chemistry, continuing to occupy the chair until 1919. During this period he published a large number of scientific papers and collected a band of enthusiastic workers in the laboratory. He took a keen interest in the incorporation of University College in the University of London and served on the committee engaged in raising the necessary funds.

In addition to his work as a physician Harley was much interested in farming, especially in shorthorns. For the last 20 years he applied scientific methods at his farm at Walton Hall and took a particular interest in forming the "Notlaw" herd. He won numerous prizes at all the big shows, was the breeder of many other prize-winners and his animals did very well in the Argentine. His Oxford Downs sheep were also successful in the show yard. In addition, he was a breeder of Shires and Large Black pigs. In 1911 he was elected a member of the council of the Shorthorn Society and served on it until his death, being president in 1918.

Prof. Harley married in 1905 Mary, eldest daughter of the late Canon Blagden, and leaves two daughters.

GEORGE HALIBURTON HUME, F.R.C.S. EDIN.,
M.D. EDIN., D.C.L.,

CONSULTING SURGEON, ROYAL INFIRMARY, NEWCASTLE-ON-TYNE

THE death on May 8th of Mr. Hume in his seventy-eighth year removed one whose name was intimately associated with surgery in the North of England. Born in Berwickshire, educated at Kelso Grammar School and Edinburgh University, George Haliburton Hume became L.R.C.S. Edin. in 1866 and M.D. in the following year, returning then to Newcastle, where he practised as a surgeon from 1868 to 1914. In 1868 he was appointed assistant surgeon to the Royal Infirmary, retiring as senior surgeon in 1905 and taking a prominent part in promoting the building of the Royal Victoria Infirmary, which was opened in 1906. His deep personal interest caused him to become the historian of the infirmary. For some years he was lecturer on physiology in Durham University, which granted him the D.C.L. in 1893, when he gave the address on the Evolution of Surgical Principles at the meeting of the British Medical Association. He also examined in surgery for the University. Mr. John Clay, one of his younger colleagues on the infirmary staff, writes:—

"Hume was a surgeon who had a wonderful influence on all around him. I can still remember as a child the awe and respect with which he was spoken of in the remote villages of Northumberland. In the operating theatres and on committees his personality seemed at once to bring about a condition of order and diligence. Although silence was suc-

a prominent feature in his character, when he spoke the words were well chosen and the matter good. His power of conveying much by few words is exemplified in the story of an operation, where the conditions found were not those that had been diagnosed. The practitioner asked him, "What shall we tell the patient's friends?" Hume's answer was, "The truth." As a surgeon he was as thoughtful as a physician, giving the greatest attention to detail in the examination of his patients. He was a patient and careful operator. In the wards he impressed his staff with the wisdom of his judgment, and the care he took in forming it. This was especially seen in his treatment for the relief of obstruction of the urinary passages, where his patient and gentle perseverance was a lesson to us all. In the building of the new infirmary he was continuously with the architect in the working out of the plans, and it is to him we are largely indebted that the hospital is so pleasant for all who work there."

Hume had worked in Berlin and Vienna as well as in Edinburgh, and his wide knowledge of surgical literature made his clinical lectures of great interest. Throughout his life as a teacher he emphasised the importance of principles, and his own consistent following of them earned for him the respect of the community.

Mr. Hume married in 1878 the daughter of Mr. Minchin Jackson, by whom he had two sons and four daughters.

JAMES MIDDLETON GRAHAM SWAINSON, F.R.C.S. ENG.

Mr. Swainson, who died suddenly on May 16th, was in his fifty-first year. He received his medical education at the Westminster Hospital, qualifying in 1896, and becoming successively house physician, house surgeon, and resident obstetric assistant. After a voyage to South America as surgeon in the Royal Mail Steam Packet service he entered the Royal Navy in 1898, obtaining a high place in the entrance examination. Having served abroad on the China station in H.M.S. *Powerful*, and desirous of particularly devoting himself to surgery, he resigned his commission in 1902, and became resident medical officer at the Queen's Hospital for Children, Hackney. In 1905 he obtained the F.R.C.S., and in the following year was appointed surgical registrar to the Westminster Hospital and assistant surgeon to the Queen's Hospital. In 1908 he was appointed surgeon to the Bolingbroke Hospital, and soon after became assistant surgeon to the Westminster Hospital, as well as surgical tutor and lecturer in minor surgery. Soon after the outbreak of the Great War Swainson was put in charge of the Scottish Red Cross Hospital at Dunkirk, and for some time carried on there the most laborious surgical work until his health completely broke down, and he returned to England altogether incapacitated. His ardent hope to practise surgery remained unrealised owing to the state of his health, and he relinquished his various appointments. Subsequently for two years he worked on the medical boards of the Ministry of Pensions. In 1921 the post of demonstrator in anatomy at St. Thomas's Hospital Medical School becoming vacant, Swainson applied for it and obtained it. His anatomical knowledge had always been extensive and accurate, and it was now with great keenness and interest that he endeavoured to perfect himself in human and comparative anatomy and embryology. This scheme, too, was unhappily frustrated by the short illness which terminated in his death. Possessing as he did a firm grasp of scientific facts and much philosophic detachment, Swainson should, with a sandler fortune, have gone far towards great success either as a surgeon or as an anatomist. His memory will be revered for the courage with which he faced his eclipsed career and the shipwreck of his hopes.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—

Sir Clifford Allbutt will be present at the annual dinner, to be held at the Café Monico, Piccadilly, on June 19th, to receive the triennial gold medal presented by the Society to a distinguished member of the medical profession.

THE SIMMINS APPEAL FUND.

THE appeal on behalf of the children of Temp.-Surg. Lieut. Alfred George Simmins, R.N., who died within a few hours of his wife on March 23rd, has evoked a ready response. The first list of contributions appeared in THE LANCET of April 21st, and the second list is now given. The fund, which has almost reached £1000, still remains open. Cheques and postal orders should be addressed to the treasurer, Simmins Appeal Fund, and addressed Royal Northern Hospital, Holloway-road, London, N. 7.

THE GENERAL MEDICAL COUNCIL.

THE summer session of the General Medical Council was opened on May 29th. Pending the election of a President, the Senior Treasurer (Mr. H. J. WARING) occupied the chair, and welcomed two new members of the Council—Sir W. Leslie Mackenzie, Crown Nominee for Scotland, who was prevented by illness from taking his place at the November session, 1922, and Prof. W. L. H. Duckworth, representative of the University of Cambridge.

Election of President.

On the motion of Sir NORMAN WALKER, seconded by Sir JOHN MOORE, Sir Donald MacAlister was re-elected President.

The President's Address.

THE PRESIDENT began by alluding to his long service of 34 years on the Council, and to the fact that he had been first elected president 19 years ago, and he thanked the Council for their invitation to enter upon another lustre of responsible duty in the chair. He continued by drawing attention to the special relations of the Council to the Privy Council and said: "In some matters the approval of the Privy Council is necessary to make our decisions operative. In others, our decisions are subject to an appeal to the Privy Council. It regulates our elections, and it advises the Crown concerning the appointment by His Majesty in Council of five members and three additional members. It applies to British Possessions and foreign countries the part of the Medical Act, 1886, which makes professional reciprocity possible. Lastly, if in anything the Medical Council neglects its duty, the Privy Council may formally direct that the duty shall be performed; and in default of obedience, the Privy Council may itself 'exercise any power or do any act or thing vested in or authorised to be done by the General Council.' Our minutes, the reports of our inspectors of examinations, our resolutions for the recognition of Colonial and foreign diplomas, and others of our Acts, are accordingly submitted officially to the Privy Council, in order that its statutory power of supervision may be conveniently exercised. Our regular work thus brings us into constant and intimate association with the Privy Council Office, and in particular with the Clerk of the Council as head of its administrative staff. Sir Almeric FitzRoy has held that responsible position since 1898, and his retirement from office, on the ground of age, is announced to take place in July. In all the 20 years during which it has been my privilege to take counsel with him on the Council's business, he has never failed to accord me his wise and sympathetic assistance, or to manifest his understanding interest in the Council's activities and in their bearings on public and professional welfare. I have had the like testimony from my predecessor in the chair, Sir William Turner, and from many other colleagues on the Council. His membership of various departmental committees and Royal commissions, such as those on physical deterioration, midwives, venereal diseases, and the Dentists Act, has made him familiar with the subject-matter of medical and dental problems which concern the Council, and has enabled him to make from his own knowledge and experience important contributions to their solution. The Council, I am convinced, will be unwilling to witness his retirement, from an office in which he has rendered such signal aid to medical and dental administration, without joining me in a cordial expression of the value we set on his public services, and of our good wishes for his health and well-being when freed from official cares."

The President noted the only change in the membership of the Council—namely, the substitution of Dr. W. L. H. Duckworth for Prof. Gowland Hopkins as the representative of the University of Cambridge, and congratulated Sir Norman Walker, the chairman of business, upon receiving the honour of knighthood.

Dangerous Drugs Act.

Concerning this Act, the President said: "A Bill amending the Dangerous Drugs Act, 1920, and in certain details the Pharmacy Act, 1868, has been the subject of considerable discussion in Parliament, and has now passed into law in an amended form. It adopts as statutory the method of calculating the percentage composition of liquid preparations prescribed in the British Pharmacopoeia of 1914. It mitigates the stringency of certain of the rules to be observed by registered medical practitioners in purchasing, procuring, prescribing, or dispensing the scheduled drugs. And, while it increases the penalties for criminal breach or evasion of the Regulations, it offers certain fresh safeguards against the officious prosecution of offenders by inadvertence. During the passage of the measure through Parliament no communication has been made to the Council by the Government Departments concerned, either on the subject of the proposed amendments, or of the alteration of the Regulations made or to be made under the Acts. But Members of Parliament who happen to be registered practitioners, among them our colleague Sir Sydney Russell-Wells, have taken an active part in the debates on the Bill. They have succeeded in so shaping the new Act as to ensure that its provisions, while carrying out our international obligation to put down the nefarious traffic in certain dangerous drugs, shall be as little oppressive as possible to practitioners whose duty it is to employ them for beneficent purposes."

The Diploma in Sanitary Science.

After bestowing a warm eulogy upon Sir George Newman's Memorandum to the Ministry of Health, on the Advance of Medical Education in England,¹ the President proceeded to call attention to the statutory registrable diploma in sanitary science, public health, or State medicine, dealt with in Section 21 of the Medical Act, 1886. "That diploma," he said, "must by law be such as 'appear to the Privy Council or to the General Council to deserve recognition in the Medical Register,' as a diploma additional to one in medicine already registered. By an Act of 1888, moreover, passed in the year after the Medical Council had recognised and registered the first diplomas in public health, such an additional diploma was made a statutory qualification for the medical officers of health of certain large areas in this country. The law thus made the Privy Council and the General Council the joint guarantors that the registrable diploma was in fact a full and sufficient technical qualification for entering on the important civil functions devolving on such medical officers. These functions have by successive Public Health Acts been multiplied and extended. It is thus the statutory duty of the Privy Council and the General Council, jointly or severally, to see to it that the conditions on which the statutory qualifying diploma is recognised and registered are correspondingly extended. The diploma of to-day must testify that the practitioner who holds it is not merely qualified to practise medicine, but qualified by special training to fulfil all the special professional and administrative duties that to-day are imposed by Statute on the medical officers of the largest civil communities in Great Britain. Naval hygiene, military hygiene, tropical hygiene, and the hygiene of British possessions and foreign countries, whose laws and usages differ from ours, are most important post-graduation studies, and in the national and imperial interest deserve every encouragement that can be afforded by the Government and by professional authorities. Special certificates of honour may properly be instituted for those practitioners who show that they have attained proficiency in these studies. I venture to submit that the Medical Council has no statutory power to control the studies or to recognise such certificates. They concern

¹ See THE LANCET, May 5th, 1923, p. 909.

only the medical authorities who quite properly may grant them, and they are not registrable in the Medical Register. These special studies and certificates, however, are not relevant to the purpose of the statutes I have quoted. They do not bear on the qualification of whole-time medical officers of health to undertake responsible civil duty in the counties and large cities of this country. The Council is thus under statutory obligation to ensure, by its rules for the granting of registrable diplomas in public health, that the course of training to which they bear witness shall be specifically a training for high civil responsibility in public health administration at home. The application of the general principles of preventive medicine to medical practice, and the several special branches of collective hygiene to which I have referred, are proper subjects of study during or after the ordinary medical curriculum. But such study does not ensure the particular kinds of knowledge and experience required to qualify a practitioner for a definitely specialised career in the administrative service of a civil community in Great Britain. The course for the diploma must, therefore, not be modified and diverted from its primary and essential purpose, merely in order that the same diploma may conveniently afford a creditable decoration for practitioners who contemplate careers other than that of the professional medical officer of health. The Council acted on that conviction when it unanimously adopted the new rules under Section 21 of the Act. Sir George Newman in his memorandum adduces weighty reasons of public policy in support of the Council's action. The Public Health Committee will probably present a report on certain communications suggesting modifications in the new rules, which have been referred to it for consideration. The Council will doubtless keep in mind, when dealing with such suggestions, the definite legal obligations it has to observe."

The President went on to say that the warning notice with respect to unprofessional advertising had been amended, and that the disciplinary work of the Dental Board had been considerable, with the result that certain cases heard before it would be submitted to the Council for adjudication. He indicated that all the time of the present session would be spent in disciplinary inquiries. He concluded by making the following statement in respect of the numbers of registered students and practitioners:—

The Statistics of the Profession.

"The rise in the number of registered medical students from 1875 in the year 1916 to 3420 in 1919 was succeeded by a fall to 1808 in the year 1921. Last year (1922) the number of entrants rose slightly, notwithstanding the higher educational qualification required by some of the bodies, to 1833. It is still some 400 above the entries for 1912 and 1913. Possibly it may now fall to a point approaching that of the pre-war years, as a result of the new regulations which came into force at the beginning of this year. The number of medical practitioners registered in 1922 was 1984, which is 224 above the number for 1921, hitherto the highest on record. The number of names removed from the Register, by reason of death or otherwise, was 1045. The result is that the total number of medical practitioners now on the Register is 46,477, which considerably exceeds any previous record. As the number of registrations in the Colonial List and the Foreign List has fallen considerably, it may justly be said that the wastage of the war has been much more than made up by fresh accessions to our professional ranks from the medical schools of Great Britain and Ireland."

Dr. CATON, in moving the adoption of the address, expressed the thanks of the Council to Sir Donald MacAlister and their pleasure at his re-election. Sir NORMAN WALKER seconded. The Council then proceeded to the elections to committees, and later to the consideration of penal cases.

FEDERATION OF MEDICAL AND ALLIED SERVICES. THE ANNUAL DINNER.

THE annual dinner of the Federation of Medical and Allied Services was held at the Langham Hotel, Portland-place, London, W., on May 29th, when the Minister of Health, the Rt. Hon. Neville Chamberlain, M.P., was the principal guest. Sir Berkeley Moynihan, the President, was in the chair, and there was a large attendance.

After the toast of "The King" had been duly honoured, the Chairman proposed the toast of "The Minister of Health," who, he said, bore an honoured name most worthily. One had to remember, he continued, that health nowadays was a very serious business, for it was no longer the concern of the individual or of the community or even of the nation. It was now a matter of international consequence. But around matters of health unhappily there had grown up many serious conflicts of opinion and a Minister of Health therefore had to walk warily. The community were at last beginning to take an interest in public health and that was all to the advantage of the Federation. If cancer was only to be cured by early research it was essential that the public should be educated to discover and report themselves very early in regard to those departures from health which cancer declared. It was difficult to draw the line between necessary reticence and adequate publicity so far as tuberculosis was concerned, and especially surgical tuberculosis, in which it was quite impossible for surgery to carry the warfare much further. Almost all of that disease was due to drinking contaminated milk. A report of the Manchester Corporation had declared that 39.5 per cent. of the milk delivered in Manchester contained active living tubercle bacilli. That milk was the food of children who were put in an incubator—the slums—where the organisms grew surgical tuberculosis, and the hospitals in Manchester and every city were filled with hundreds and thousands of patients who came back over and over again with a disease which should have been prevented in its earliest stages. Public health could no longer be studied unless the public played their part. One of the lessons which we had learned during the war was that no campaign could be planned or launched unless regard were paid to the casualty lists, for the strength and striking power of the army depended upon the health of the troops. It was the same in industry as in war, and captains of industry were beginning to realise that if they were to carry on their work with the largest profit they must have regard to the welfare of the men working for them. In this connexion the Federation was playing an important part. Its annual report showed that industry after industry was beginning to realise that the Federation was giving them substantial help in this matter, but if the work was to extend and grow it was necessary that further financial support should be forthcoming. The great resources of the Federation in technical knowledge were at the disposal of the Minister of Health, and the Federation would be proud to be made the medium of help in every possible way.

Mr. Neville Chamberlain, in responding, said that there might be more health in his official title than in any of his functions, but he was glad to know that there was a body like the Federation with such vast stores of knowledge and experience to which he could turn for advice and counsel. Ever since he had been interested in public work he had been impressed by the thought that there was no greater benefit that statesmanship could confer on the people of any country than that of improving the public health. No man could enjoy life unless he was physically fit, and unfortunately side by side with the great advance in our civilisation there had grown up new conditions, a greater congestion of population, a higher nervous pressure, and a general increase in the pace at which

we lived that had made increased demands on the human frame and had to some extent destroyed the advantages we might have hoped to have derived. Anything that could be done to raise the standard of health and to teach people how to be healthy was calculated to do more for happiness, prosperity, and efficiency than anything else to which they could turn their minds. He was glad to hear Sir Berkeley Moynihan refer to the coöperation with industry because he felt convinced that that was a valuable sphere of operation. Having regard to the many diseases that prevailed, the causes of which were obscure, it seemed to him that there was nothing they could more fruitfully devote their attention to than the prosecution of research. But more opportunities and more inducements must be provided for men to engage in research. Doctors could not do that and at the same time carry on a general practice in order to live. It could not be doubted that the efforts made in recent years to grapple with scarlet fever, measles, cancer, and other dangerous enemies of mankind, had borne good fruit, for in the years that followed the war, despite all its consequences in suffering and depression, the vital statistics of the country were never so favourable. He supposed that some day they would have a complete health policy for the country, and it would have to come about under a Minister that was fortunate enough to remain in office for more than a few months at a time. He did not pretend to say what that policy would be, but he thought we could even now see where our weak spots lay. The institutional accommodation was inadequate. We had physicians and surgeons who were second to none, but we did not make the best use of their services, nor of the nurses. To attain an efficient health policy all the resources at our disposal had to be used, and it was because the Federation could help in that matter that he wished it all prosperity and success.

In the unavoidable absence of Mr. Charles Carpenter, D.Sc., Vice-Chairman of the Citizens Council, Sir Thomas Horder proposed "Our Guests," coupling with the toast the names of the Rt. Hon. Lord Riddell and Sir William Hale-White, President of the Royal Society of Medicine. These gentlemen having replied, Mr. Ernest Clarke proposed a vote of thanks to Colonel Mummery, the honorary secretary, who in his reply said that the Federation was now working in a very satisfactory way, though there was an adverse financial balance, but he hoped that before another year had passed that balance would be on the right side of the account.

During the evening Mr. Frederick Dawson, a friend of the President, charmingly entertained the guests at the piano. The following were among those present:—

Sir Berkeley Moynihan; Rt. Hon. Neville Chamberlain, M.P.; Sir Walter Kinneir, Controller, Insurance Dept., Ministry of Health; Lord Riddell; Sir William Hale-White, President, Royal Soc. of Medicine; Dr. Herbert Spencer, President, Medical Soc. of London; Sir Arthur Robinson, Permanent Secretary, Ministry of Health; Mr. Alfred Salmon; Mr. W. A. Ward-Jones; Dr. J. Blomfield; Dr. R. McNair Wilson; Mr. Laurence Brock, Assist. Secretary, Ministry of Health; Mr. Cyril Watts; Mr. E. T. Neathercoat, President, Pharmaceutical Society; Sir Bruce Bruce-Porter, representing the Vermin Repression Society; Mr. Harold Morris, K.C., M.P.; Mr. Henry Lesser, LL.B., Hon. Sec., Citizens Council; Sir Charles Macara; Major J. E. Molson, M.D., M.P.; Lt.-Col. F. E. Fremantle, M.P., Chairman, Parliamentary Medical Committee; Lt.-Col. Nathan Raw; Sir Charles Gordon-Watson; Sir Thomas Horder, Chairman, Federation Medical Council; Lord Dawson of Penn; Col. Howard Mummery, Medical Director, the Federation; Commander O. Locker-Lampson, M.P.; Dr. Howard Marshall; Miss Montgomery, R.R.C., representing the Assoc. of Hospital Matrons; Sir Thomas Neill, Chairman, Council, National Health Insurance, Ministry of Health; Mr. J. P. Lockhart-Mummery, F.R.C.S.; Mr. E. Fitzgerald Frazer, F.R.C.S.I.; Sir Malcolm Morris, Vice-President of the Federation; Mr. W. P. Crocker; Sir J. Herbert Parsons, F.R.S.; Mr. Ernest Clarke, F.R.C.S., Vice-Chairman, Medical Council; Dr. R. A. Gibbons; Dr. Jane Walker, Joint Hon. Sec. of the Federation; Mr. W. A. Workman, representing Legal and General Assurance Soc., Ltd.; Dr. J. F. Gordon Dill, Joint Treasurer of the Federation; Sir J. Dundas-Grant; Mr. F. W. Davy; Mr. Montagu Hopson, L.D.S., representing the

British Dental Assoc.; Dr. Charles Buttar, Joint Hon. Sec. of the Federation and representing the Harveian Society; Prof. Frederick Hobday, representing Nat. Veterinary and Medical Assoc.; Mr. R. D. Blumenfeld; Miss Barton, representing the Poor-Law Infirmary Matrons Assoc.

Medical News.

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL.—The distribution of prizes by the Duke of Connaught will take place in the Governors' Hall of the hospital on June 13th, at 3 P.M.

HOSPITAL SAVING ASSOCIATION.—At a meeting of the Metropolitan Counties Branch of the B.M.A., held on Tuesday last, a report was discussed on the contributory scheme of the Hospital Saving Association, when the meeting unanimously endorsed the condemnation by the report of the mode of admission of out-patients.

OPENING OF HEATHERWOOD HOSPITAL, ASCOT.—This hospital, which has been built by the United Services Fund to deal with cases of surgical tuberculosis among children of ex-Service men, was formally opened on May 29th by H.R.H. the Duke of Connaught. The building provides accommodation in three wards for 150 patients—babies, girls, and boys.

LONDON ASSOCIATION OF THE MEDICAL WOMEN'S FEDERATION.—A meeting was held at the Elizabeth Garrett Anderson Hospital on May 15th, with Dr. Louisa Martindale, the President, in the chair. Miss Octavia Lewin read a paper on Personal Hygiene and its Place in School Teaching, giving instances that had come under her notice of inadequate provision of facilities for personal hygiene. These included insufficient lavatory accommodation in schools, absence of handkerchiefs and of the knowledge of their use, overtight clothing, and indiscriminate kissing of children even when suffering from infectious diseases. Dr. Lewin discussed the various sources from which education on personal hygiene may be expected: (1) the parents; (2) the teachers; (3) the public libraries and the press. Dr. Lewin said how she had found in the Encyclopædia at the British Museum that the pages dealing with disease were so thumb-marked as to be almost illegible. She also showed cuttings of the quack medicines advertised in one issue of a daily paper, which were so numerous as to cover a whole sheet of the paper. A discussion followed in which Drs. M. F. Jevons, A. Parsons, L. Fairfield, L. Wilson, Elmsley, H. Hanson, J. Lane-Clayton, A. Hutchinson, and E. Handley Read took part, showing what is actually being done by the school medical service to deal with the problem.

IRELAND AND THE PASTEUR CENTENARY.—Several representatives from Ireland have been attending the Pasteur Centenary celebrations. The Government of the Free State is represented by Dr. George Sigerson, who as a young man studied in Paris more than 60 years ago. Dublin University has sent one of its most distinguished medical graduates, Sir Alnroth Wright, while the National University of Ireland is represented by Mr. James Merriman, President of University College, Cork, and Dr. J. O'Connor, Professor of Physiology in University College, Dublin.

MEDICAL SERVICE IN CONNEMARA.—A deputation representative of the medical practitioners in Connemara had an interview last week with officials of the Local Government Board, at which they pointed out the condition under which dispensary doctors worked in the county and drew attention to the fact that the sum of £42,000 per annum was provided by the British Government for proper medical service for the Highlands and Islands of Scotland, the doctors being assured of a net income of £50 a year after the payment of all expenses. In Connemara and the poorer parts of Galway the present medical officers were unable to make a living. Connemara in particular was the home of tuberculosis, typhus, and typhoid, and quite a number of doctors had lost their lives through disease and accident in endeavouring to alleviate the sufferings of the poor. A couple of doctors had died of absolute poverty, and within recent years five had died of typhus alone. The deputation made certain recommendations as to the improvement of salaries. It is not an uncommon thing for doctors in Connemara to have to travel 200 miles per week in the discharge of their duty, some of them were unable to afford a motor car, and those who had to hire a car often found their salary wiped out by the bill for travelling expenses. The representatives of the Local Government Department were favourably impressed and assured the deputation that their claims would be sympathetically considered when dealing with the medical scheme, which is expected to come before the Dail shortly.

ASSOCIATION OF ECONOMIC BIOLOGISTS.—The annual field meeting of the association will be held at Cambridge on June 15th. The laboratories and investigations in progress on animal nutrition and physiology in the School of Agriculture will be demonstrated. The laboratories of the National Institute of Agricultural Botany and Seed Testing Station and the field trials of agricultural crops will be inspected, and at the University Farm and Plant Breeding Institute investigations in progress on cereal hybridisation will be shown. Those intending to be present are asked to notify Mr. W. B. Brierley, Rothamsted Experimental Station, Harpenden, Herts, on or before June 6th.

LEAGUE OF NATIONS HEALTH COMMITTEE.—The matters under discussion at the sixth session of the League Health Committee, which began in Paris on May 26th, show the development of inter-Governmental co-operation in public health matters in the two years since the foundation of the League Health Organisation. As regards epidemiological intelligence and public health statistics, a regular and rapid collection and distribution of information has been initiated, and it is hoped that the organisation will become a central clearing house for all such matters. The progress of the three committees of inquiry working under the auspices of the organisation is also under discussion. Of these committees, the first is investigating the prevalence of sleeping-sickness and tuberculosis in tropical Africa since the war. The second and third are joint subcommittees of, respectively, the League Opium and Health Committees on the one hand, and the Health and Transit Committees on the other. The Opium and Health Subcommittee is conducting an inquiry into the quantity of opium and other dangerous drugs required annually by the various nations for legitimate purposes, as part of the campaign against the illicit drug traffic now being conducted by most of the Governments of the world. The Health and Transit Subcommittee is collecting information for a conference between the various European States having navigable inland waterways, for the purpose of co-ordinating and tightening up sanitary control and anti-epidemic measures without interfering with the normal functions of these arteries of trade. Further reports concern the applied research work on a common plan in laboratories scattered all over the world, undertaken during the last year and a half under the auspices, and on the initiative, of the Health Organisation, and aiming at international agreement on methods of testing and measuring the strengths of sera and serological tests. A similar programme is proposed in regard to certain biological products used as powerful drugs, such as insulin, digitalis, and pituitary extract. In the field of executive work and co-ordination between various health administrations attention is drawn to the courses in anti-epidemic work for public health officials that are being conducted under the auspices of the Health Organisation in Warsaw, Moscow, and Kharkov, where the need for trained personnel is so acutely felt. The question of further perfecting and developing the system of visits for international groups of public health officers studying the sanitary systems of one or two countries is also under discussion. By an arrangement concluded with the Soviet Russian delegation at the Genoa Conference, the members of the Health Committee, together with a delegate from the Central Health Authorities of Soviet Russia, constitute a special international commission for discussing the anti-epidemic campaign as it affects Russia.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY, Burlington House, W.

THURSDAY, June 7th.—4.30 P.M.

Papers to be read:—Sir Charles Sherrington, P.R.S., and E. G. T. Liddell: Stimulus Rhythm in Reflex Tetanic Contraction. K. N. Moss: Some Effects of High Air Temperatures and Muscular Exertion upon Colliers. (Communicated by Dr. J. S. Haldane.)

Paper to be read in title only:—F. A. E. Crew: The Significance of an Achondroplasia-like Condition met with in Cattle. (Communicated by Sir Arthur Keith.)

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETINGS OF SECTIONS.

Wednesday, June 6th.

SURGERY: at 5.30 P.M.

Papers:

Mr. R. H. A. Whitelocke: The Treatment of Fractures of the Patella.

Mr. Winsbury White: The Closure of the Suprapubic Fistula following Prostatectomy; Observations on 68 Cases.

Thursday, June 7th.

OBSTETRICS AND GYNÆCOLOGY: at 8 P.M.

Specimens:

Dr. Herbert Spencer: (1) Sarcomatous Ovarian Dermoid. (2) Ruptured Carcinoma of Ovaries; no Recurrence. (3) An Effect on the Fallopian Tube of Torsion of an Ovarian Tumour.

Dr. Russell Andrews: A case of Carcinoma of the Cervix in a Woman of 77 associated with Prolapse of the Uterus.

Papers:

Mr. Victor Bonney: Diurnal Incontinence of Urine in Women.

Mr. Leonard Phillips: The Treatment of Dysmenorrhœa with Analysis of 100 Cases.

Friday, June 8th.

OPHTHALMOLOGY: at 8.30 P.M. (Cases at 8 P.M.)

Annual General Meeting:

Election of Officers and Council for 1923-24.

Cases:

Mr. H. M. Joseph: Progressive Macular Changes associated with Tremors.

Mr. Montague Hine: Three Cases of Hereditary Corneal Opacities.

Papers:

Miss Ida Mann: Some Suggestions on the Embryology of Congenital Crescents.

Mr. P. Doyne: The Tournée Reaction.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East, S.W.

THURSDAY, June 7th.—5 P.M., First Croonian Lecture: Prof. J. B. Leathes: The Role of Fats in Vital Phenomena.

FELLOWSHIP OF MEDICINE POST-GRADUATE LECTURES, 1, Wimpole-street, W.

TUESDAY, June 5th.—5.30 P.M., Mr. R. A. Hendry: The Value of Antenatal Supervision.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY, June 4th.—12 noon, Mr. Simmonds: Applied Anatomy. 2.30 P.M., Dr. Saunders: Medical Wards. 3 P.M., Mr. Simson: Diseases of Women.

TUESDAY.—10 A.M., Dr. Drummond Robinson: Gynæcological Operations. 11 A.M., Dr. McDougall: Electrical Department. 2 P.M., Mr. Banks-Davis: Throat, Nose, and Ear.

WEDNESDAY.—10 A.M., Dr. Saunders: Medical Diseases of Children. 2 P.M., Dr. Burnford: Medical Wards. 3 P.M., Dr. Pernet: Skin Department.

THURSDAY.—10 A.M., Dr. Grainger Stewart: Neurological Department. 12 noon, Mr. Simmonds: Demonstration of Fractures. 2 P.M., Mr. MacDonald: Genito-Urinary Department.

FRIDAY.—10 A.M., Mr. Dudley Buxton: Dental Department. 11 A.M., Dr. McDougall: Electrical Department. 3 P.M., Mr. Sinclair: Surgical Out-patients.

SATURDAY.—9.30 A.M., Dr. Burnford: Bacterial Therapy. 10 A.M., Dr. Saunders: Medical Diseases of Children. 10 A.M., Mr. Banks-Davis: Operations on Throat, Nose, and Ear.

Daily, 10 A.M., to 6 P.M., Saturdays, 10 A.M., to 1 P.M., In-patients, Out-patients, Operations, Special Departments.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C. 1.

POST-GRADUATE COURSE: MAY-JUNE, 1923.

CLINICAL LECTURES AND DEMONSTRATIONS.

MONDAY, June 4th.—2 P.M., Out-patient Clinic: Dr. Hinds Howell. 3.30 P.M., Neuropathic Keratitis: Mr. Paton.

TUESDAY, June 5th.—2 P.M., Out-patient Clinic: Dr. Grainger Stewart. 3.30 P.M., Tropic Disorders in Disease of Nervous System: Dr. Hinds Howell.

THURSDAY, June 7th.—2 P.M., Out-patient Clinic: Dr. Kinnier Wilson. 3.30 P.M., Disordered Gaits in Nervous Disease: Dr. Hinds Howell.

FRIDAY, June 8th.—2 P.M., Out-patient Clinic: Dr. Gordon Holmes. 3.30 P.M., Myasthenia Gravis: Dr. Saunders.

COURSE OF LECTURES ON NEURO-PATHOLOGY.

MONDAY, June 4th.—12 noon, Pathology of the Neuron: Dr. J. Godwin Greenfield.

A COURSE of 12 LECTURES on the ANATOMY AND PHYSIOLOGY OF THE NERVOUS SYSTEM will be given at 12 noon on TUESDAYS and FRIDAYS if there are sufficient entries for it.

Mr. Armour and Mr. Sargent operate at the Hospital on Tuesday and Friday mornings at 9 A.M., or at such other times as may be announced.

The fee for the whole Course is £12 12s., including Anatomy and Physiology, but these Lectures may be taken separately for a fee of £4 4s. The fee for the Course without Anatomy and Physiology Lectures is £10 10s. Special arrangements as to fees will be made for those unable to take the whole Course. Fees should be paid to the Secretary of the Hospital at the office on entering for the Course.

C. M. HINDS HOWELL, Dean of Medical School.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.
Demonstration of Clinical Cases at 3.30 P.M.

MONDAY, June 4th.—Mr. J. Bright Banister: Gynaecological.
TUESDAY.—Dr. J. Metcalfe: Radiological.
WEDNESDAY.—Mr. C. H. Hayton: Throat and Nose.
THURSDAY.—Dr. Yealland: Medical.
FRIDAY.—Mr. E. Gillespie: Surgical.

NORTH-EAST LONDON CLINICAL SOCIETY, Prince of Wales's General Hospital, Tottenham, N.

THURSDAY, June 7th.—4.15 P.M., Dr. A. J. Whiting: The General Signs of Cerebral Tumour.

LONDON HOSPITAL MEDICAL COLLEGE, Mile End, E.

WEDNESDAY, June 6th.—4.15 P.M., Dr. W. M. Feldman: Foetal Physiology.
FRIDAY.—4.15 P.M., Mr. A. J. Walton: The Thyroid Gland.

LONDON SCHOOL OF MEDICINE FOR WOMEN, 8, Hunter-street, W.C.

TUESDAY, June 5th.—5 P.M., Prof. A. L. McIlroy: Foetal Welfare and Mortality.

INSTITUTE OF PATHOLOGY AND RESEARCH, St. Mary's Hospital, Paddington, W.

THURSDAY, June 7th.—4.30 P.M., Prof. F. G. Hopkins: An Oxidising Agent in Living Tissues.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.

THURSDAY, June 7th.—4 P.M., Dr. A. M. H. Gray: Eczema.

INFANTS HOSPITAL, Vincent-square, S.W. 1.

MONDAY, June 4th.—6 P.M., Dr. Eric Pritchard: Milk Analysis, &c.

TUESDAY.—8.45 P.M., Dr. Vincent Denne: Prophylaxis in the Treatment of Teeth in Infancy.

THURSDAY.—6 P.M., Dr. Eric Pritchard: Examination of Urine and Stools of Infants.

FRIDAY.—8.45 P.M., Mr. Philip Franklin: The Causes, Treatment, and Prevention of Adenoids and Enlarged Tonsils.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone-road, N.W.

THURSDAY, June 7th.—5 P.M., Mr. L. C. Rivett: Venereal Disease in Pregnancy.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE LECTURES.

TUESDAY, June 5th.—4.15 P.M., Mr. F. H. Westmacott: Mastoid Disease.

UNIVERSITY OF BRISTOL POST-GRADUATE DEMONSTRATIONS.

MONDAY, June 4th.—At Hereford, Mr. T. Carwardine: Abdominal Pain and Its Causes.

Appointments.

MISBAH, A. N., M.D., Ch.B., D.T.M., D.P.H. Liverp., F.R.C.S. Edin., has been appointed Principal Medical Officer for the Government Hospital, Aswan, Egypt.

POTTS, T. N. V., M.B., B.S. Durh., D.Hy., D.P.H., Assistant Medical Officer of Health, Newcastle-upon-Tyne.

RYAN, V., M.B., B.Ch. N.U.I., Assistant Resident Medical Officer, Winsley Sanatorium, near Bath.

TORRENS, J. A., M.D., B.S. Lond., F.R.C.P. Lond., and SMITH, E. BELLINGHAM, M.D., B.S. Lond., M.R.C.P. Lond., Physicians to St. George's Hospital.

Vacancies.

For further information refer to the advertisement columns.

Aberdeen Royal Infirmary.—Asst. S.

Birkenhead Borough Hospital.—Hon. Radiologist.

Blackburn County Borough.—Asst. M.O.H., &c. £600.

Boole Borough Hospital.—Hon. Gyn. S. Also Hon. S. to Ear, Nose, and Throat.

Brentwood Mental Hospital.—Jun. Asst. M.O. £510.

Bristol General Hospital.—Clinical Assts.

Charing Cross Hospital Medical School, W.C.—Pathological Chemist. £400.

Derbyshire Royal Infirmary, Derby.—H.S. £200.

Dublin, Dr. Steevens' Hospital.—Hon. Obstet. P. Hon. Dent. S.

Eastbourne, Princess Alice Memorial Hospital.—Res. H.S. £175.

Elizabeth Garrett Anderson Hospital, Euston-road.—Asst. S.

Epsom, Queen Mary's Convalescent Centre.—Jun. M.O. £350.

Fife and Kinross Joint Sanatorium.—Res. Asst. M.O. £250.

Glasgow, Gartloch Mental Hospital.—Locum Tenens. £350.

Guildford, Royal Surrey County Hospital.—H.S. £150.

Hampstead General and North West London Hospital, Haverstock Hill, N.W.—H.P., H.S., and Cas. M.O. Each £100.

Hertford County Sanatorium, Ware Park, near Ware.—Asst. M.O. £300.

Hull Royal Infirmary.—Hon. Asst. S.

India, Countess of Dufferin's Fund.—Two Medical Women. Rs.550 per mensem.

Lancaster County Mental Hospital.—Asst. M.O. £440 17s.

Leamington Spa, Warneford, Leamington, &c., General Hospital.—Res. H.P. £150.

London County Mental Hospital Service.—Seventh Asst. M.O. £440.

London Lock Hospital, 91, Dean-street, W.—Clin. Assistantships. Maidstone, Kent County Ophthalmic Hospital.—H.S. £300.

Metropolitan Ear, Nose, and Throat Hospital, 2, Fitzroy-square, W.—Asst. S.

North Middlesex Hospital, Edmonton, N.—Asst. M.O. £200.

Oxford, Radcliffe Infirmary and County Hospital.—H.P. £200.

Portsmouth Royal Hospital.—Sen. H.S. £200. Also Two Asst. H.S.'s. Each £150.

Royal Dental Hospital of London, 32, Leicester-square, W.C.—House Anæsth. 10s. 6d. per attendance.

Royal Free Hospital, Gray's Inn-road, W.C.—H.P., H.S., Asst. Cas. O., Obstet. H.S. Also H.S. and Obstet. Asst. £50.

Royal Northern Hospital, Holloway, N.—Ophth. S.

St. Lucia, Victoria Hospital.—Res. S. £500.

St. Mary's Hospital for Women and Children, Plaistow, E.—Hon. P. and Hon. Asst. P.

St. Peter's Hospital for Stone, &c., Henrietta-street, Covent Garden, W.C.—Clinical Assts.

Ventnor, Isle of Wight, Royal National Hospital for Consumption.—Asst. Res. M.O. £300.

Welsh Board of Health.—Female M.O. £600.

Western Dispensary, 38, Rochester Row, Westminster.—Res. Med. Pract. £100.

Western Australia Lunacy Department.—Sen. Asst. M.O. £552.

West London Hospital, Hammersmith-road, W.—H.P. and H.S. Each £100. Also Asst. Anæsth. and Hon. Med. Radiologist.

West Middlesex Hospital, Isleworth.—Asst. Med. Supt. £350.

Workmen's Compensation Act: Ophthalmic Specialist Medical Referee for County Court Circuits Nos. 24 and 30 (Brecknockshire, Monmouthshire, and Glamorganshire).

Applications should reach the Private Secretary, Home Office, S.W., not later than June 16th.

Births, Marriages, and Deaths.

BIRTHS.

CRUICKSHANK.—At 9, Royal Crescent West, Glasgow, on May 24th, to Dr. and Mrs. J. N. Cruickshank (Dr. May Slimmon)—a daughter.

FORWARD.—On May 19th, at Northmead Cottage, Farnham Common, the wife of Dr. E. L. Forward, of a son.

FRANCIS-WILLIAMS.—On May 15th, at Hillside, Dowlais, the wife of Cecil Francis-Williams, M.R.C.S. Eng., L.R.C.P. Lond., of a son.

McFADYEAN.—On May 18th, at "San Remo," Herne Hill, S.E., the wife of Kenneth McFadyean, M.R.C.S., L.R.C.P., of a son.

ROGERSON.—On May 17th, Dorothy M. Rogerson, M.A., wife of Dr. Rogerson, Broadway, Bexley Heath, of a daughter.

SAWDAY.—On May 25th, at 29, Hartington-street, Derby, to Winifred (née Amos), wife of A. Ernest Sawday, M.B., B.S. Lond.—a daughter.

SCOTT.—On May 21st, at Coupar House, Blandford, the wife of Lieut.-Colonel L. Bodley Scott, M.D., I.M.S., of a son.

SPRENT.—On May 23rd, at a nursing home, Chester, the wife of W. S. Sprent, M.D., of a son.

DEATHS.

COLLINS.—On May 20th, Walter Charles Grosett Collins, M.D.

HARLEY.—On May 21st, very suddenly, at Walton Hall, Edward Vaughan Berkeley Harley, M.D., M.R.C.P., of Harley-street and Walton Hall, Bletchley, aged 59 years.

HARRISON.—On May 18th, at Granville-gardens, Shepherd's Bush, after a long illness, Henry Francis Egbert Harrison, M.R.C.S., L.R.C.P., in his 78th year.

HEGGS.—On May 19th, at Woodborough-road, Nottingham, from the after-effects of gas poisoning in the war, Major Francis Raymond Mitchell Heggs, M.R.C.S., L.R.C.P. Lond., E.A.M.C., T.F., aged 48 years.

HERAPATH.—On May 19th, at "Stoneleigh," Cotham Park, Bristol, Charles Kynaston Coathupe Herapath, M.R.C.S., L.R.C.P.I., aged 69 years.

KNIGHT.—On May 7th, at West Norfolk and King's Lynn Hospital—following an operation—Frederick Charles Rienzi Malins Knight, M.R.C.S., L.R.C.P. Lond., of Watlington, Norfolk (late of 43, Claremont-square, N.), beloved husband of Winifred Knight and son of Dr. Charles Knight, of Letchworth.

PETTER.—On May 24th, at Netherlaw, Darlington, Walter Petter, M.B., C.M. Edin.

WILSON.—On May 25th, at Watergate, Grantham, Richard Wilson, M.R.C.S., aged 77 years.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

THE LATE DR. H. F. E. HARRISON.—Henry Frank Egbert Harrison, who died on May 18th at his residence in Shepherd's Bush, at the age of 78, was for over 40 years medical officer to the Hammersmith Guardians. Educated at Epsom College, he entered St. Mary's Hospital, and qualified L.R.C.P. Lond., M.R.C.S. Eng. in 1869. Dr. Harrison settled in practice in Shepherd's Bush, where, until he became afflicted with the long illness which terminated his active career, he was a well-known figure. His popularity with his wage-earning patients led to the sobriquet of the "friend of the poor," his friendship manifesting itself both in kindly action and in sympathetic intercourse. To his son, Dr. W. L. A. Harrison, and other members of his family our sympathy is extended.

Notes, Comments, and Abstracts.

MENTAL HYGIENE IN CANADA.¹

BY C. K. CLARKE, M.D., LL.D.,

PROFESSOR OF PSYCHIATRY, UNIVERSITY OF TORONTO;
MEDICAL DIRECTOR OF THE CANADIAN NATIONAL
COMMITTEE FOR MENTAL HYGIENE.

CANADA being a developing country, where population is sparse and territories enormous, it is almost inevitable that the cost of building and maintaining institutions for the mentally ill should be a heavy burden on a population lacking wealth, as so much had to be undertaken in a short time. The wonder is that anything was accomplished. Again, when it is remembered that the host of immigrants drifting from the old world always contain an undue proportion of defectives and mentally diseased it may be understood that our problem has been by no means a simple one.

Dangers of Indiscriminate Immigration.

Resentment is sometimes shown in Great Britain because we take exception to certain types of immigrants, and deport many individuals who wish to become citizens. But the success of a nation depends almost entirely on the character of its population, and a reading of past history makes it abundantly plain that if we are to preserve the rugged qualities which have characterised our people in the past we shall scan the immigrant coming across the seas very closely. It is a normal defence reaction.

Rudyard Kipling and others say that what Canada must do is to pump in the population. That is true, but at the same time it is necessary to put the suction pipe in waters not polluted by defect, physical degeneracy, and social failure. It must be frankly admitted that our public men are greatly influenced by American ideals, and our politicians are following the footsteps of Uncle Sam closely in the endeavour to rob Europe of its needy millions, with little attempt to sort out the types drifting across the seas. Anthropology is not recognised as a science by these enthusiasts, and the history of the rise and fall of other nations is rarely suggested as a topic worthy of the study of the parliamentarian; but the intelligent study of emigration, not immigration, is the most essential thing in Canada to-day. The United States have long ago discovered that Canada as a whole has been occupied by sturdy Nordic types of efficient and capable people to whose descendants they have extended a warm welcome, with the result that we have suffered enormously by the loss of many of our best. If the immigration had been made up of hardy Nordic agriculturalists such as we had 100 years ago all would have been well. Unfortunately, that is not what happened, and apparently is not likely to happen again. The United States have learned their lesson, but realise that it is too late to profit by it. Their best thinkers feel that the damage has been done, and whatever their idealists injected into their original constitution, they are now convinced that all men are not born equal, and that it is possible to scale down to a new depth rather than rise to greater efficiency. But Canada is now entering upon an era of movement in the other direction; our greatest hope is in the importation of good Nordic types from the United States, and this movement is becoming more and more extensive.

The Problem of Child Immigration.

Possibly child immigration needs more careful supervision than any other, as it so frequently includes physical and mental weaklings. Child immigration would be invaluable if of the right kind under rigid psychiatric inspection, as the children grow up in touch with our ways and of course adapt themselves easily, but if they are of the wrong kind they add enormously to our burdens and troubles. To show that the danger is real, let us scan some accurate statistics regarding some 5800 children referred for examination to a National Mental Hygiene psychiatrist. These were special cases; 1386 were mentally subnormal to such a degree that they were incapable of acquiring an ordinary school education. Of this group only 25 per cent. were Canadians, 33 per cent. were foreign born, and the remainder children of recently arrived immigrants. In one clinic alone, in a short time, 107 girls and 24 boys of the most defective and degenerate types, brought by one child immigration society, have come before my notice. Nearly all the girls were persistently immoral, the majority unmarried mothers, many earning a living on the street; altogether they constituted a serious menace to the health and happiness of the community. It is said, of course, that they had been residents of the country for some time before they went astray; the reply is, that ■

careful inspection before sending them and a rigid sorting at the port of arrival would have weeded them out. To carry on the latter inspection is most difficult, but the point is that it should not be necessary.

The Position of Psychiatry in Canada.

That research should have fallen by the wayside is not to be wondered at, and that psychiatry as a subject should for many years have occupied only a subordinate position in the medical curricula of the universities was inevitable. The relations between general medicine and psychiatry have been anything but intimate, and as a rule provincial governmental control of institutions resulted in a lowering of standards.

We passed through the various stages which marked the trail of the self-educated psychiatrist all the world over, and only too often adopted the numerous classifications which emanated from the fertile imaginations of those exploiting them. It was not unusual to find an enthusiast who had a new classification for every case he met—indeed history is now repeating itself along these lines—and a panacea for mental disease was discovered a dozen times a year. On the other hand, it must be admitted that medical education ignored psychiatry to a great extent, and provided little or no instruction for the student. To read some of the modern writers on vocational training and industrial pursuits in hospitals for the insane one could almost believe that these things were recent discoveries, and yet in October, 1862, Dr. Jarvis, of Dorchester, Mass., read a remarkable article before the Association of Medical Superintendents of American Institutions for the Insane, entitled *Mechanical and other Employments for Patients in the British Lunatic Asylums*, in which he showed conclusively that in many of the British asylums occupational therapy (as it is now grandiloquently styled) was developed in a thorough manner. It proved that the experiment was carried on in Britain about 1840, or even earlier, and was continued with increasing confidence for many years.

Psychiatric Experience in Toronto.

After the failure of our psychiatric hospital scheme in Toronto we felt that it would be well to fight for ideals outside of a public service, to scan psychiatry from a new point of view, to lay the foundation for the broader teaching of students, and to educate public opinion along better lines. We established a psychiatric outdoor clinic at the Toronto General Hospital, and interested every social agency in the city—juvenile court, public health, immigration and police departments, social service agencies of all kinds, school physicians and nurses, industrial homes and schools, &c. In a short time we had the whole city working for us, and the clinic has become a powerful factor in the control of juvenile criminality and prostitution, as well as the education of the public to the modern attitude of medicine towards the prevention of evils which have been so manifest and yet difficult to deal with heretofore.

It was felt wise to interest the department of psychology in the University of Toronto in the problem of mental defect. Psychology was ranked as a subdepartment of philosophy, and it did not seem possible to emancipate it from philosophy and physics. Eventually the tide turned and we succeeded in getting not only the coöperation of the psychologists, but their hearty backing, and a great deal of the measuring of intelligence of certain groups of children is being done by them in our clinic. Psychology is coming into its own, and while the wave of excitement, caused by the discovery that psychology has a part to take outside of abstruse speculation, has carried the hyper-enthusiasts too far, yet the well-balanced group, who always save such a situation, realise the true rôle of psychology in the future. No matter how much some psychiatrists may resent the claims of certain psychologists to divine inspiration along special lines of mental investigation, it must be remembered that psychiatry itself has a good many sins and failures to answer for. Even with all the aid given by pathological and clinical investigation, as well as research, can we truthfully assert that psychiatry has kept pace with general medicine as a whole?

The fact that some criticism of psychology and the enthusiasms of psychologists is indulged in does not mean that the importance of psychology is not recognised; on the contrary, it is believed that every psychiatrist should be thoroughly grounded in psychology and psychological methods. Now that psychology has been placed on a footing which makes it rank as a valuable contributor in the study of mental action and behaviour, its claims to recognition cannot be denied, and we should make use of everything it has to offer.

Psychiatry and the War.

We had our outbursts of enthusiasm in certain circles over psycho-analysis, Freudian theories, and sex problems ad nauseam, but it was when war broke out the neo-psychiatrists neuro-psychiatrists, and psychological healers of all kinds found themselves. Shell-shock was their particular fad,

¹ An abstract of the fourth Maudsley Lecture given before the Medico-Psychological Society of Great Britain and Ireland on May 24th, 1923.

and as each performer recited his recoveries, quite oblivious of the truth that the other fellows who employed totally opposite methods of treatment had also 100 per cent. of recoveries, the public stood in amazement at the miracles being performed, and wondered what psychiatry had been doing during all the centuries it had existed. Of course, there were some poseurs, but many of the young men were self-deluded, and, confounding cause with effect, really believed that they could set the whole world straight in a few weeks. Even yet the truth has not yet dawned on a moiety of perfectly honest observers.

Conscription in Canada bore heavily on groups of mental defectives and mildly insane young men who had found their niche in simple farm work or occupations of a routine nature, and the change resulting from the removal to a new environment requiring more mental agility than they possessed resulted in disaster after disaster. But possibly the most valuable fact gleaned from the experience was the discovery that there are many mentally diseased and handicapped persons capable of becoming useful hewers of wood and drawers of water in communities, where, in the past, many were too regularly institutionalised. It means a further linking up of psychology and psychiatry and the using of men trained along psychological lines was applied to vocation and industrial fitness. We have recognised this side in our mental hygiene experiences, and have used with advantage a well-trained official in connexion with the development of this part of the work.

Narrowing Tendency of Institutional Work.

Emancipation from asylum life soon makes it plain that the institution physician is living in a contracted sphere, because after all his medical association is largely with terminal cases; he sees nothing of the evolution of mental disease, particularly in childhood, and is out of touch to a great extent with general medicine. Heads of institutions are necessarily occupied to a great extent with administrative duties, and taking the world as a whole, staffs of the great majority of asylums are so small that research and study cannot be carried on in the best way possible.

The public is really looking for the guidance we have denied it, and when in the past psychiatry has vouchsafed to respond to the request for further light, it has covered its message with a mass of scientific verbiage that no one without the pale could understand. In other words, the aloofness of psychiatrists shut up within the walls of custodial institutions has simply added to the popular misconception of mental disease and given a mysterious tinge to something that should be much better understood by the man on the street. It is only by following such lines as this the amateur dispensers of auto-suggestion and so-called psycho-analysts of similar type can be kept within bounds.

The Mental Hygiene Movement.

When one thinks of the mass of magnificent work done clinically by those who have had time to study the brilliant pathological findings by such investigators as Mott, it is a matter of wonder that so little has been accomplished in the way of actual cure. We must frankly confess that the progress made is not what might have been expected. Experience proves that we have neglected the first principles of preventive medicine, that the road to success lies in the direction of early prevention of mental disease.

It is recognised by the people, when the facts are placed before them, that many methods of the past are simply the outcome of a hopeless and pessimistic attitude that accepts the curse of mental disease as an inevitable and incurable disaster, not far removed from the realm of criminality. Governments not only look to mental hygiene committees for advice, but depend on them to outline and direct many public enterprises. It is true that while the better care of the insane was the motive of the work of Clifford W. Beers, who developed the original Mental Hygiene Committee in the United States, it has been found that this is only a small part of the work to be done. Psychiatrists must no longer be mere custodians of people overtaken by a dire calamity, but aggressive leaders ready to show their mettle in a great cause.

More good has been done by the mental hygiene movement in Canada in five years in the way of improving the care of the insane, the study of defectives, the education of the public opinion to a realisation of the importance of these problems, than was accomplished in half a dozen decades preceding that period. Take, for example, an analysis of 3442 cases under 16, met with in our clinic, and we learn that no less than 8 per cent. could definitely be classed as suffering from mental disease or psychopathic inferiority.

If we are honest we must confess that psychiatry is merely at alpha in its book of knowledge, and that although brilliant work has been done in pathology and clinical investigation an increased recovery rate can scarcely justify us in saying that we have solved or even guessed at the causes of mental disease or indicate just how the law of prevention is to be applied.

Dementia Præcox.

Take the scrap-heap called dementia præcox. Experience during recent years leads one to believe that careful investigation carried on in schools, psychiatric clinics, and juvenile courts, will demonstrate the fact that the victims of the psychosis may nearly always be detected at any early age. It is most important to learn how much prevention can do to steer the patients clear of the tragedy ordinarily awaiting them. At all events it is apparent that biochemical problems, studies in metabolism, in fact a whole series of laboratory investigations, along the most advanced lines are required.

Some of the younger group of enthusiasts who scoff at the influence of heredity, and talk learnedly about environment as the cause of the majority of misfits, pooh-poo the occurrence of dementia præcox at early age, and assert that nearly all cases of children who show the symptoms of this disease clear up eventually. I wish that such were the truth, but unfortunately I have seen during their developmental stage too many cases which eventually decline into complete dementia.

Of course, it will be pointed out that after all eugenics will do more than anything else to solve the problem, but no matter how wonderful eugenics appear in theory, as long as human nature remains as it is the application of eugenics as taught by some ultra-modern teachers will prove not only difficult but nearly impossible. Extreme methods will invariably produce violent reactions, and it is a simple matter to acquire the label "crank" if enthusiasm interferes with the sentiment tradition has woven about marriage. It is difficult to steer between the Scylla of tradition and the Charybdis of eugenic enthusiasm. The very fact that so little satisfactory work has been done on the psychoses of children is in itself evidence that the matter has escaped the attention of most psychiatrists. The physicians in hospitals for the insane are often without practical experience in the matter, and those who are innocent of psychiatric training overlook what is obvious to the skilled observer. Careful investigation shows that in very early life the evolution of many cases of mental disease may be studied—it is to be hoped with advantage to the patient.

The Teaching of Psychology and Psychiatry at the University of Toronto.

It appears that the time has come to revise our methods of educating psychiatrists. So strongly do we feel on the matter that in the University of Toronto we have developed an optional course covering five years in psychology and psychiatry. After much thought we have outlined a course of options and already a group has advanced to the fourth year of the six years' course. They are receiving 60 hours a year of special training in psychology and psychiatry during five years. Out of 80 who applied for the option some 35 of the most brilliant were selected, and this group has been carefully weeded. During their second year in medicine they received a training in elementary psychology. In their third year a course of 60 hours in more advanced as well as experimental psychology is being given, and the students advised to take additional training in chemistry and physics. The fourth year has had 60 hours devoted to abnormal psychology, the exposition of the modern attitude of psychology towards mental defect and mental disease, taking in, of course, the theories of the Freudians, the psychoanalysts, &c. Practical work in the way of applying mental tests to normal and abnormal children has been given, with the idea of making the student familiar with the true value of mental tests, but showing also how they often fail to reveal the whole story. The fifth and sixth years of the course will be largely clinical, the work being carried on in the psychopathic hospital and psychiatric clinic at the Toronto General Hospital. These institutions are certain to offer no end of useful clinical material, which under our law is always available. Such a course will, we hope, equip a band of young psychiatrists with a training of the most useful kind, ready not only to undertake institutional work if necessary, but to carry on practice among mentally diseased persons who do not require treatment in institutions.

We feel that research must not be limited to institutions, but must be put on the broadest basis possible, and include persistent investigation of mental development and mental disease in child life. Such a plan as that adopted in the Toronto schools must eventually become a common one, and means intelligent co-operation between school boards and public health departments; the public health department assumes full authority for the inspection of children and lays out the programme to be followed by the educational authorities in dealing with abnormal types. A psychiatric department exists, and is proving a powerful influence for good; when its industrial and farm schools are in operation further advances will take place. Psychology only too often arrogates to itself the right to deal with the abnormal child, feeling certain that it is able to prescribe the proper treatment. Much as we are indebted to psychology for the

splendid work done among children of low intelligence, there has been failure in the understanding of school pupils suffering from mental disease. To admit otherwise would be to recognise charlatanism as justifiable and advisable.

Intelligence Tests and Precocity.

Our experience with different intelligence tests has now been so great that we are in a position to estimate their value as well as appreciate their inadequacy. Unfortunately, their apparent simplicity and ease of application have resulted in the stimulation of the ambition of hosts of amateurs, especially teachers, whose work is harmful, being limited by lack of vision and knowledge, or a proper conception of the significance of the tests. They cannot understand the danger of accepting a standard of intelligence telling merely a portion of the story, and ignoring the part of it necessary to complete a picture of the child's mind and personality. An outburst in another direction is also under active development, and in psychological and pedagogical circles the discussion of the "supernormal" child waxes warm. The term supernormal is unfortunate and unscientific, as it gives a false impression, and by too many psychologists is loosely applied to a group including well-developed children above the average in intelligence and physique, as well as a group of physical and mental weaklings measuring high by the Binet-Simon scale. In them precocity is the outstanding feature, and their doom under ordinary circumstances easily foretold. What will happen to them under the forcing process so frequently recommended is well known to asylum physicians, who constantly see these wrecks stranded early in university and scholastic careers. Possibly there is little chance of saving them under any circumstances, but there is no argument in favour of hurrying the calamity.

Education of the Public.

The most important part of the work of the Canadian National Committee for Mental Hygiene is to educate people to a knowledge of the importance of having well-educated psychiatrists abroad in the community with the idea of helping to keep the importance of prevention ever in mind, and to scan school populations with a skilled eye with the hope of forestalling a thousand and one tragedies such as one sees to-day.

The psychiatrist of to-morrow must be able to grapple with problems concerning individuals who are social misfits, to analyse behaviour problems of all kinds, and to give advice regarding the mental hygiene of the whole community. It is obvious that outdoor departments or dispensaries should exist in connexion with many institutions near urban centres, although this is more easily accomplished in general hospitals or psychopathic clinics, where facilities for thorough examination exist and laboratory findings are obtainable at a minimum cost. Possibly there is more red tape here in connexion with institutional matters than is the case beyond the sea, but the persistent attempt to break down the barriers imposed by tradition and ignorance is bearing fruit with us. The clinics have robbed the institutions of much of the stigma formerly attached to them. Voluntary admissions are growing in number; so much might be said along these lines that one hesitates to open the subject. Then, again, the importance of prevention must never be forgotten. To do all this it is evident that psychiatrists must be emancipated from a great part of the administrative work which they are frequently ill-trained to do efficiently. They must be given large staffs of specially trained social workers and nurses to carry on follow-up work as well as investigations of home conditions.

The reaction against the purely psychological point of view in school adjustments of mentally handicapped pupils has already shown itself in certain centres, and if the greatest good is to follow the survey of school populations, psychiatrists must equip themselves to carry out this work in the best way possible, for after all it is distinctly a medical problem. How can a psychologist, for example, diagnose and prescribe for a developing case of a manic-depressive or a dementia præcox psychosis? More than ever before we must now take stock of the assets and liabilities of psychiatry. The public must be shown its just reasons for existence, its readiness to adjust itself to the new order of things, and a constructive ability to do something more than merely provide custodial care for those who have fallen by the wayside.

THE PROPERTIES OF COD-LIVER OIL.

Dr. E. Poulsen, professor of pharmacology at the University of Christiania, has prepared a pamphlet, issued by the proprietors of Dr. De Jongh's cod-liver oil (Ansar Harford and Co., Ltd., 182, Gray's Inn-road, London, W.C. 1), in which the medicinal properties of cod-liver oil and the reasons for its employment in disease are set out. The nutritional value of cod-liver oil is well known, and in this pamphlet of some 16 pages its accessory food factor content is discussed in a clear and succinct manner.

HOSPITAL TREATMENT FOR MIDDLE-CLASS PATIENTS:

A SUGGESTED SCHEME OF INSURANCE.

IN an address delivered at the Annual Conference of the British Hospitals Association, held at Sheffield on May 31st, Sir Napier Burnett confined his observations to the income side of hospital finance, and outlined a suggested basis of insurance for hospital patients within certain income limits, £250 to £600 or so (class "B" patients). We give the scheme in abstract substantially in his own words.

The Disabilities to be Met.

The serious financial position of many patients belonging to this class, when overtaken by accident or sickness, requires no special pleading; in many cases such patients are ineligible for admission to a general hospital because of rules laid down in the original charter. During the past 20 years many advances have been made in scientific medicine and surgery, and to keep abreast of these developments elaborate and expensive apparatus has been devised in the equipment of the many new departments that have had to be established to meet the needs of specialisation. Such apparatus leads to a greater precision in the diagnosis and treatment of disease.

The benefits of these scientific attainments are now available for class "C" of patient, but those of moderate means, debarred from the private hospital or nursing home because of the cost, are yet unable to participate in the benefits of modern hospital scientific resources. At present class "B" patients whose annual income exceeds £250 may receive hospital treatment in one of the following ways, namely:—

1. A certain number now find their way into the hospital wards, either as members of a contributory scheme which has no fixed income limit, or they are admitted as the result of some emergency illness, and while in hospital they may or may not be assessed towards the cost of maintenance by the hospital almoner.

2. A comparatively small number of the larger hospitals has recently followed the lead given by many of the cottage hospitals in setting aside a small number of beds for paying patients. Such beds usually show a high percentage of occupation, indicating that they are meeting a real need. Patients admitted to those reserved beds are charged from 2-5 guineas per week towards the cost of maintenance, and in some hospitals the patient also pays for treatment, making his own financial arrangements with a member of the hospital medical staff. General hospitals in this country have not been designed, as in America, to provide separate accommodation for patients paying varying rates either towards maintenance or treatment, with the result that patients in adjoining beds occasionally find themselves paying different rates and consequently are prone to question the equity of the arrangements; whereas in other hospitals the medical staff are not expected to charge the patients in the paying wards for their services. Such an arrangement is likely to lead the medical officer to the opinion that his services are being exploited by the hospital if he is asked to treat patients of a financial status considerably above those with respect to whom his services were contracted for in a voluntary capacity.

3. Again, a class "B" patient may be admitted to a general hospital as a member of some insurance scheme, such as the Sussex Provident Scheme, which undertakes to pay to the hospital the total cost of maintenance plus an agreed percentage to the medical staff for every member in the scheme treated by the hospital. But the maximum income limit of the Sussex scheme is fixed at £350 for husband, wife, and family (up to 16 years of age), and the annual premium for the provision of hospital treatment when required, plus dental and ambulance service, &c., is £2.

The Scheme Set Out.

The main objection to the various arrangements whereby the middle-class patient can receive hospital treatment (with the exception of the Provident Scheme referred to) is that the heavy expenditure for both maintenance and treatment falls on the patient at the very time when he is least able to afford it—namely, when his income is cut off. The ideal scheme will doubtless be reached some day, when there shall be a hospital bed available for any member of the community who requires hospital treatment. In the meantime, the following scheme is submitted as a contribution towards the solution of a difficult and urgent problem.

Provided that the actuarial foundations are sound, a voluntary insurance scheme possesses many advantages. I suggest that, by a system of insurance, hospital provision might be arranged for the class "B" with an income, say, between the limits of £250 and £600 or £700 per annum, the premium for such insurance to be at the rate of £2 per

annum, with the option of paying quarterly or half-yearly. In illustration, let me give the following figures.

Say that in one community there are 5000 people between the income limits above mentioned, who voluntarily join an insurance scheme, in order to obtain hospital treatment when necessary, and when accommodation is available, on the basis of £2 per annum, the hospital would collect £10,000, which would be kept as a pool apart from the other hospital funds. The first call on the pool would be payment to the hospital of the total cost of maintenance of all insured patients treated during the year. The sickness incidence amongst class "C" is a known quantity—namely, 2 per cent. require hospital treatment. The sickness incidence in class "B" is considerably less, and also there is not the same liability to accident, but in order to provide a margin of safety, and also to include husband and wife, let us double the rate in "C" class and allow 4 per cent. of sickness incidence. Out of the 5000 people insured, some 200 might require hospital treatment during the year. Further, if we calculate the average total cost to the hospital of each in-patient as £10, roughly 3 guineas per week, and an average length of stay of three weeks, the hospital would receive £2000 in full payment of the total cost of the insured patients treated. This payment would leave a balance of £8000 in the pool.

The medical staff could not reasonably be expected to render voluntary service; therefore I suggest that the second charge on the pool should be payment to the medical staff, and in order to remove from the wards all possibility of varying tariff charges, an agreed percentage of the pool might be paid into a medical staff fund, to be apportioned by the medical men themselves to their individual members on the basis of work done. Again, to allow of a margin of safety the maximum figure of 50 per cent. may be withdrawn from the pool towards such a fund—that is, a sum of £4000. The further balance of £4000 remaining in the pool after meeting the total charges incurred by the hospital, and the payment to the medical staff, represents the real insurance quota, or so-called profit of the scheme, and this sum should be utilised in the provision of increased accommodation and facilities for the treatment of class "B" patients.

Critical Examination of the Scheme.

Two criticisms of such a scheme readily suggest themselves—namely: (1) The ability of hospitals to supply the requisite accommodation implied by the scheme without in any way interfering with the provision for class "C"; and (2) the machinery for administering the scheme. In regard to (1), a certain number of class "B" make use of the hospital beds as it is. Again, dealing with the figure mentioned in the illustration—namely, 200 patients per annum, as the sickness incidence of the 5000 insured people, that number would roughly represent 13 beds, with an average overturn of 15 patients per bed per annum; further additional accommodation could be provided from the surplus funds as the scheme develops. With regard to the nature of the accommodation, in a number of hospitals paying patients are satisfied to be treated in small wards set aside for the purpose and screened off into cubicles. With regard to (2) the scheme might be carried out by some recognised insurance company already possessing the necessary collecting machinery, but this would deprive the hospital of the outstanding benefit under the scheme. The requisite machinery might quite well be provided by the existing contributory scheme organisation.

The three outstanding advantages that such a scheme, as roughly outlined, would possess are:—

- (1) That the elaborate equipment and facilities for the diagnosis and treatment of disease now possessed by the modern voluntary hospital and obtainable to the same extent nowhere else, would be available for an additional and very deserving section of the community.
- (2) A fresh avenue of finance would be opened up for voluntary hospitals.
- (3) Payment would be provided for the hospital medical staff.

RUSSIAN DOCTORS IN NEED.

To the Editor of THE LANCET.

SIR,—The Russian doctors and medical staff in the famine-stricken regions are in a very difficult situation as they are left without resources, and are deprived of means for bringing help to the thousands of sufferers. Many hospitals and dispensaries in the villages, organised by the efforts of the Russian Red Cross and the Commissariat of Public Health, are compelled to stop their activities because of the lack of funds, medicaments, and surgical instruments. The regions where the population was exhausted by famine are at present centres of endemic and epidemic diseases, dangerous not only to Russia, but also to the rest of the world. Infectious diseases, including consumption, typhus, typhoid fever, and malaria are raging, while severe diseases

of the digestion, in consequence of the famine, are widely spread. It is urgently necessary that help should be rendered from abroad and that an energetic campaign should be continued against the consequences of famine. The Russian medical services alone are unable to master the situation. We appeal to the feeling of solidarity of the medical and scientific men of Great Britain and America, and hope that they will answer generously to the appeal for help of their Russian colleagues.

Donations in money or in kind may be sent to the Secretary of the Medical Aid Committee for Sufferers from the Russian Famine, 68, Lincoln's Inn-fields, London, W.C. 2.

We are, Sir, yours faithfully,

V. N. POLOVTSSEV, Chairman.

May 24th, 1923.

L. HADEN GUEST, Vice-Chairman.

PSORIASIS OF THE NAILS.

To the Editor of THE LANCET.

SIR,—I wonder if any of your readers could give me any useful information about the treatment of chronic psoriasis of the nails. Chrysarobin, besides being unpleasant, has proved of little benefit after many months' trial.

I am, Sir, yours faithfully,

May 22nd, 1923.

"BAULKED."

AMBULANCE COMPETITION TESTS.

Messrs. John Bale, Sons and Danielsson, Ltd., have issued at the price of 3d. each a series of folders for the use of ambulance students preparing for competitions. They contain up-to-date tests with detailed marking sheets and useful hints with regard to training—what should be done and what should not be done. The tests are well worked out, and should afford valuable help for those undergoing their training in first aid.

Parliamentary Intelligence.

HOUSE OF LORDS.

TUESDAY, MAY 29TH.

Smoke Abatement.

Viscount ASTOR asked the Parliamentary Secretary to the Ministry of Health when it was proposed to introduce legislation with regard to smoke abatement. If the Bill was not introduced at an early date it would be impossible to pass it this session.

The Earl of ONSLOW said that the Government intended to introduce a Bill in their lordship's House to deal with this subject. The measure was in process of drafting, and there would be no great delay in its introduction.

HOUSE OF COMMONS.

MONDAY, MAY 28TH.

Coroners' Legislation.

Sir BERTRAM FALLE asked the Secretary of State for the Home Department when he proposed to bring in the new Bill dealing with coroners.—Mr. G. LOCKER-LAMPSON (Under-Secretary to the Home Office) replied: A Bill is in course of preparation, but my right hon. friend is not in a position to say when it will be possible to introduce it.

TUESDAY, MAY 29TH.

Sanitation in Rural Districts.

Captain REGINALD TERRELL asked the Minister of Health if he was aware that in many country districts there was a complete absence of effective sanitation, which on medical assertion might be a serious danger to public health; and whether, seeing that local authorities were inclined to regard the necessary outlay as an undue burden on the rates, he would provide assistance by way of an unemployment grant thereby accomplishing a double benefit.—Lord E. PERCY replied: My right hon. friend is aware that the sanitary conditions are not satisfactory in some country districts, and that the difficulties in the way of improving matters are mainly financial. In cases where the degree of local unemployment is sufficient to warrant an unemployment grant any schemes submitted by local authorities will receive consideration.

Registration of Deaths and Burials.

Dr. SALTER introduced a Bill to amend the law relating to the registration of deaths and burials, which was read a first time.

A Lecture

ON THE

CHOROID PLEXUSES AND VENTRICLES OF THE BRAIN AS A SECRETING ORGAN.

Delivered at the Middlesex Hospital on June 5th, 1923.

By SIR JOHN BLAND-SUTTON, F.R.C.S. ENG.,

CONSULTING SURGEON TO THE MIDDLESEX HOSPITAL.

ALTHOUGH my theme is a morbid condition of the brain, I propose to set before you a parallel in pathology connected with the kidney which may help to explain the remarkable nature of the ventricles of the brain.

A PATHOLOGICAL PARALLEL.

The kidney is a compound gland which strains liquid from the blood. This liquid—urine—charged with products, secreted by the epithelium lining the uriniferous tubules, collects in the pelvis of the kidney and is conveyed by the rhythmic muscular action of the ureters to the urinary bladder, from which it is discharged at convenient intervals. Occasionally the escape of urine from the ureter or from the bladder is hindered, and this hindrance leads to its accumulation in the excretory duct—the ureter, pelvis, and calyces of the kidney—and as they distend the pressure causes the kidney to be gradually converted into a multilocular sac. Coincident with this distension, the muscular tissue of the ureter and the glandular tissue of the kidney slowly disappear. This end-result is known as hydronephrosis. Kidneys are often converted into sacs of this kind before birth. Ante-natal hydronephrosis proves that kidneys are functional in the late stages of foetal life, and this lends support to the opinion that the bath of amniotic fluid, or hydrosphere, in which the foetus floats contains urine.

The damaged urinary organs shown in Fig. 1 belonged to a male infant that only survived its birth a few days. They are represented by a sacculated kidney and a greatly dilated ureter on the right side. There is a small circular perforated diaphragm where the ureter opened into the bladder, but it offered no obstruction to the flow of water from the ureter into the bladder when tested. There were no traces of the left kidney or its ureter. Retention and slow accumulation of urine had destroyed the glandular tissue of the kidney and rendered the boy unfit to live.

HYDROCEPHALUS.

Recent researches into the physiology of the choroid plexuses of the brain prove that they act as glands, and the secretion they furnish is known as cerebro-spinal fluid. These plexuses grow luxuriantly from the surfaces of the velum interpositum in relation with the ventricles of the brain. They are vascular, covered with a single layer of epithelium, and differ in construction from glands in general in having the secreting cells on the surface of the plexus. Experimental evidence indicates that the bulk of the fluid is secreted above the aqueduct of Sylvius. The fluid secreted by the choroid plexuses collects in the cerebral ventricles, and the narrow canal, or iter,

which tunnels the corpora quadrigemina establishes communication with the fourth ventricle. The fluid escapes by means of the lateral recesses into an irregular space at the base of the brain, and forms a pool called the cisterna magna.

The cerebro-spinal fluid occupies the arachnoid spaces of the brain and spinal cord, and exists under considerable pressure. There is no external orifice for the discharge of the fluid, and the evidence available indicates that it is absorbed by veins. Regarded as a secretion, the cerebro-spinal fluid exists under peculiar conditions, and it is formed in late foetal life. Interference with its escape from the ventricles causes the retained fluid to produce changes on the brain which are parallel with those seen in hydronephrotic kidneys.

When both lateral recesses of the fourth ventricle are occluded in foetal life the effect on the brain is disastrous. In the head of the child shown in sagittal section (Fig. 2) the lateral ventricles are dilated and form a common cavity with the third which is many times larger than normal; the infundibulum is also involved and so distended that it has flattened the

hypophysis into a thin wafer. The fourth ventricle is dilated, the vermiform process of the cerebellum is effaced, and the choroid plexuses, the secreting elements, have vanished. The brain of this child has been as surely damaged by the pressure exerted by the slow accumulation of retained cerebro-spinal fluid as renal tissue in advanced hydronephrosis. Like the hydronephrotic boy, this hydrocephalic child survived its birth only a few days. The difficulty in investigating congenital hydrocephalus arises from the softness of the brain, especially in the foetal stage. The occlusion of ducts and passages is a common and inexplicable event in foetal life.

In the parallel examples of kidney and brain the organs were destroyed during foetal life and rendered post-natal life impossible. Minor degrees of such changes in kidneys, or in the brain, are not incompatible with life. Many years ago I urged that examples of extreme hydronephrosis found in adults for which no adequate cause could be assigned were due to causes acting during foetal life. This is certainly true of hydrocephalus. Changes beginning before birth may progress with extreme slowness after birth. Here is an example:—

A baker, aged 29, was admitted into the Royal Infirmary, Edinburgh, for fits and other symptoms indicating intracranial pressure. He was submitted to a decompression operation. At the end of a month the symptoms returned and an attempt was made to establish permanent drainage, but he died 36 hours later. The brain was preserved and carefully examined by Mr. J. N. J. Hartley, who gave me facilities for examining it and obtained some excellent photographs. The brain is shown in sagittal section (Fig. 3.) The

FIG. 1.

Urinary organs with the right adrenal of a new-born boy; they show the disastrous effects of ante-natal hydronephrosis.

FIG. 2.

Sagittal section of the head of a hydrocephalic child. The head of the arrow is in the fourth and the feathers in the third ventricle. The infundibulum is widely dilated, the pituitary fossa expanded, and the hypophysis flattened. (Museum, Middlesex Hospital.)

ventricles are greatly distended and the choroid plexuses atrophied. The choroid plexus of the fourth ventricle is obliterated. The third ventricle is converted into a globular cyst which bulged into the circle of Willis, and separated the optic chiasma and the carotid arteries; it also flattened out the hypophysis. *Each lateral recess of the fourth ventricle is completely blocked by a thin diaphanous membrane which juts out like a stunted cone near the flocculus, and separates the roots of the big nerves which lie in this region of the medulla. The occluding membrane is best displayed at the right recess (Fig. 4).*

Occasionally unilateral occlusion of a recess is followed by the formation of a cyst the size of a cherry and a fringe of choroid plexus floats in the fluid which distends it. Such a condition is sometimes called hydrocele of the fourth ventricle. Unilateral occlusion does not lead to hydrocephalus, but such a cyst has produced facial palsy, deafness, anaesthesia of the corresponding side of the face, and other symptoms referable to pressure on the roots of the great nerves connected with this important region of the brain.

Morowoko made a careful microscopic investigation of the choroid plexus in patients dying from general paralysis of the insane. He suggests that the choroid plexus in foetal life exercises its functions, and confirms the view that the choroid gland may be regarded as the main producer and regulator of normal cerebro-spinal fluid, and is the filter of toxic products and passes into the blood the toxic waste products of the nervous system.

In addition to the fluid secreted by the choroid plexuses there is a complex gland which discharges secretion into the third ventricle—i.e., the hypophysis.

It is regarded by physiologists as a ductless gland. I feel sure the infundibulum acts as a duct to the hypophysis; some of its products escape into the third ventricle and mingle with the cerebro-spinal fluid. Occasionally the third ventricle is occupied by colloid stuff, perhaps pseudomucin, which when seen after death resembles jelly, but after the brain has been immersed in hardening solution it assumes an appearance like softened glue. These gelatinous masses have been described as sarcomas of the third ventricle! Dr. J. G. Greenfield showed me one and shrewdly suggested that this colloid stuff is a pathological fluid discharged into the ventricle from a disordered hypophysis.

TUMOURS.

The ventricles of the brain with the choroid plexuses not only agree with the kidney, in principles of construction and function, but in their liability to epithelial tumours. The comparison of the kidney with the cerebral ventricles does not end merely with the effects produced by obstruction to the escape of the secretion, but there is striking agreement in the methods of obstruction. A choroid plexus resembles in principle the Malpighian corpuscle of the kidney, in which a single layer of epithelium covers a vascular coil; the secretion is discharged into the convoluted portion of the uriniferous tubule.

Epithelial membranes are liable to grow papillomas, and when growing luxuriantly in a narrow conduit a clump of papillomas is a very serious obstruction in the adits either of the brain or of the kidney. It is established by the experiments of Dandy and Blackfan that the greater part of the cerebro-spinal fluid is secreted above the aqueduct of Sylvius, and the experimental blockade of this adit leads to rapid and fatal hydrocephalus. Clinical observations agree with the experimental results. The escape of fluid from the lateral ventricles can be hindered by tumours in three situations—at the entrance and at the exit of the aqueduct, and by simultaneous occlusion of the lateral recesses of the fourth ventricle.

The most instructive and impressive examples arise in connexion with the fourth ventricle. The posterior half of the roof of this cavity is very rich in villi

FIG. 3.

Brain in sagittal section showing great distension of the ventricles secondary to occlusion of the lateral recesses of the fourth ventricle. From a man aged 29.

when they transform into papillomas the cavity may be so stuffed with them that the aqueduct of Sylvius is effectually obstructed and the fluid accumulating in the lateral ventricles distends them. The narrow aqueduct in such circumstances may be dilated until it is as big as a goose-quill. The symptoms associated with such conditions are as tragic as simultaneous

obstruction of both ureters, but less amenable to surgical treatment.

The most remarkable form of tumour obstruction is caused by bilateral tumours arising in the choroid plexuses as they emerge from the lateral recesses of the fourth ventricle. These picturesque tufts float in the cerebro-spinal fluid of the cisterna magna; when the

of which are recognised as sequential to damage of the hypophysis.

FORAMEN OF MAGENDIE.

In text-books of anatomy reference is made to a hole in the membranes at the apex of the calamus scriptorius which marks the lower end of the cavity of the fourth ventricle. This hole, called the foramen of Magendie, is supposed to be the means by which cerebro-spinal fluid escapes from the ventricle into the subarachnoidean space. In 1879 I satisfied myself by repeated examination of the brain in situ that the foramen was made in the course of dissection.¹ I have made many examinations since that date and have satisfied myself that it is an artefact. Cleland writes in regard to the foramen of Magendie, "it can be easily demonstrated to be artificial if the dissector is on his guard."² This foramen has had such charm for teachers that it maintains a place in text-books, although sealed up by practical anatomists many years ago.

Modern knowledge of the cerebro-spinal fluid justifies the following summary. The ventricles of the brain serve as temporary receptacles for the fluid secreted by the choroid plexuses; also some secretion from the hypophysis. The fluid escapes through the lateral recesses of the fourth ventricle into the arachnoid area for absorption.

Cerebro-spinal fluid is physiologically useful. Its excessive accumulation does not lead to toxic symptoms, but its retention in gross quantities leads to disaster from pressure effects. The unrestrained escape of the fluid is quickly fatal in children. In the variety of spina bifida called myelocoele the central canal of the cord and the dural sheath open on the skin in the lumbo-sacral region. Many fetuses with this defect are stillborn, and those born alive rarely live more than a few days. In children persistent leakage of the cerebro-spinal fluid is incompatible with life.

Fig. 4. Under surface of the cerebellum of the brain represented in Fig. 3, showing occlusion of the lateral recesses of the fourth ventricle.

tufts grow abnormally and form clumps of papillomas, they become smothered in fibrinous exudation which not only cements the papillomas together but encases them in a compact mass, the outer part of which is often stratified like the layers of an onion. When such tumours are examined microscopically, the papillomas, in section, are represented by circular bodies; the centre of each contains blood-vessels and tissues in various stages of degeneration. The tissues are infiltrated with cholesterol; in some tumours this substance is so abundant that the mass gleams like mother-of-pearl; they are often called in consequence cholesteatomas and xanthomas (sand-tumours). These tumours do not so effectually blockade the ventricle as papillomas occupying the fourth ventricle, but they lead to grave and fatal consequences.

There is a rare variety of tumour which arises from the infundibulum and blocks the inter-ventricular communication by pressure on the corpora quadrigemina (Fig. 5). The tumour, which equals a walnut in size and in shape, grows from the fundibulum and bulges into the third ventricle. The hypophysis preserves its size and shape, but is intimately associated with the tissue of the tumour. The third and the lateral ventricles of the brain are much dilated because of the accumulation of cerebro-spinal fluid. The obstruction is caused by the pressure of the tumour on the corpora quadrigemina closing the aqueduct of Sylvius.

Tumours of the infundibulum have been reported by Erdheim (1904) and Strada (1911). They have a peculiar structure and resemble very closely that of an epithelial tumour, but for the moment I am mainly concerned with the manner in which these tumours interfere with inter-cerebral communications and also set up curious symptoms, some

Hypophyseal-duct tumour. The brain in sagittal section. The infundibulum is replaced by a tumour which pressed on the quadrigeminal bodies, closed the Sylvian aqueduct, and led to distension of the lateral and third ventricles. Semi-diagrammatic. (Museum of the Middlesex Hospital.)

Complete obstruction of the inter-ventricular communication, in children and adults, is as inimical to life as complete obstruction of both ureters.

BED ISOLATION AND THE CONVEYANCE OF INFECTION WITHIN A WARD.¹

By FREDERIC THOMSON, M.B.,
C.M. ABERD., D.P.H.,

MEDICAL SUPERINTENDENT, NORTH-EASTERN HOSPITAL, LONDON.

My object in writing this paper was twofold. First a hope that it would lead to considerable discussion, and so help to elucidate the ways in which infection may be carried from one person to another within a ward. My second object was to sound a note of caution, for conclusions have been deduced from published results which, in my opinion, are unwarrantable and even dangerous.

I will quote the following expression of opinion referring to "bed isolation" in a leading article in THE LANCET of August 19th, 1922. It is as follows:—

"But a high standard of ventilation and of conscientiousness in nursing are of value in themselves, and the extra time and attention seem but a small price to pay for a system which makes it possible for any sanitary authority to treat within small compass all the infectious cases in the area which need special care. The experimental stage is past and the time has come for general reform along the same lines."

I am not clear whether the writer of these words considered that small-pox did not require special care, that it could be safely treated in a "bed isolation" ward, or that it was not an infectious disease. Doubtless he would say he did not mean to include small-pox, but there can be no doubt that he did mean to include chicken-pox, measles, and other infectious diseases. Even with that modification I imagine there will be few who are experienced in these diseases who would accept the statement, and I think most would regard it as altogether too sweeping.

Before speaking of "bed isolation," I think it necessary to consider briefly in what manner infection is supposed to be transmitted within a ward. In days gone by the dangers of infection were greatly exaggerated, and when I say this I refer only to expert opinion, for even now one finds medical men of high standing in their own particular branch of medicine or surgery who do not at all like the idea of even visiting a fever hospital, apart altogether from entering a fever ward. To go back only 40 years, and to take scarlet fever as an example, it was held that infection might occur from contact, from being in the same room, in the same house, or even in the neighbourhood of the house in which the sufferer was resident. Advancing to the year 1896 we find Goodall and Washbourn saying that the contagion of scarlet fever, measles, variola, varicella, and typhus fever is commonly conveyed through the air. The interesting suggestion is also made that some bacteria through their minuteness are more readily conveyed by air than others.

Avenues of Infection.

At the present time it is more or less agreed that the most common mode of infection is direct or indirect contact. Some of us scoff at the aerial conveyance of infection, and some would even call droplet infection infection by indirect contact. Then we are told that droplet infection is dangerous only in the immediate surroundings of the infector, that it is all a question of virulence and dosage, though a small dose will infect some while others require a larger one. We are agreed, I suppose, that flies or other insects may convey infection from one patient to another, though it would seem from the experiments in "bed isolation" that this seldom occurs.

On the subject of air-borne infection there is obviously great difference of opinion, some considering it common, some considering it uncommon yet admitting it to be possible for short distances, while

others appear to disbelieve in its occurrence. Apparently I have been regarded as a believer in air-borne infection by those who seem to regard droplet infection as infection by indirect contact. It has been my custom to consider coughing and sneezing at close range as contact infection, and a mass of mucus the size of a split pea can be coughed from a tracheotomy tube a matter of five or six feet. I have, however, regarded droplet infection as air-borne infection, and one cannot say how far droplet infection sufficient to amount to infect can be conveyed. We are told by some that the distance is limited to the immediate surroundings of the infector, but I can find nothing to guide me as to what that really means. During Dr. M. H. Gordon's investigation concerning the ventilation of the debating chamber of the House of Commons he recovered infected plates 50 ft., 61 ft., and one at the roof 71 ft. away from the individual who endeavoured to broadcast the *Bacillus prodigiosus* by speaking. These were, of course, the greater distances, and it does not follow that a dose sufficient to infect could be carried these distances. But, on the other hand, it can be conceived that under favourable conditions this might happen.

I infer the droplet to be invisible, that if it alights on one's mucous membranes or skin the contact is not felt, and that it can be propelled a greater distance than the infector than the plug of mucus I have referred to. If it struck an air current it would seem reasonable for conveyance to be somewhat further, and then if it became attached to a minute floating fragment of cotton-wool it would travel an even greater distance. If it hit a fly the fly might convey it a considerable distance, perhaps to a patient's lips, if it hit the finger of a nurse the same might happen. I take it all these things, and more, are possible, but that salvation comes in the fact that as the droplets are propelled into space none of them is likely to occur with any frequency. I have a leaning towards the suggestion of Goodall and Washbourn, made 27 years ago, that the minuteness of the microbe may have something to do with the distance infection is conveyed, since the smaller the droplet the further it might be carried. It is, I presume, a possibility that a droplet could contain a sufficient dose of certain infectious diseases, and that a dwarf droplet could contain a potent dose of others. Further, that in certain stages of some of the infectious diseases may be possible for droplets to be potent enough to convey infection. Therefore, to my mind it would be wise to defer judgment of the distance infection can be air-borne in a ward until we have information upon which we can rely, and I submit that we have not yet obtained that information.

Literature of Bed Isolation.

Doubtless "bed isolation" is being, or has been carried out at hospitals of which I am unaware, but I propose referring to the work of Drs. J. Biernacki, F. G. Crookshank, E. H. R. Harries, D. MacIntyre, and C. Rundle. Also I would like to include my own work, since, although that was carried out to gain as much possible, more information about the mode of conveyance of infection, yet the methods adopted in the ward were those of "bed isolation." I am unaware of the details of the work of Drs. Biernacki and Harries and possibly they have not been published. Dr. Crookshank and Rundle give some information, unfortunately do not give sufficient for others to deduce from with accuracy. On the other hand, Dr. MacIntyre is careful to supply information, and I have endeavoured to do the same.

All I can find about Dr. Biernacki's work is contained in Dr. MacIntyre's article in THE LANCET of August 19th, 1922, where we are informed that between 200 and 300 cases during two years and that the cross infections were one of scarlet fever and two of chicken-pox. Dr. Crookshank treated 120 cases of scarlet fever and 73 of diphtheria in wards, and he also treated enteric fever, erysipelas, measles, rubella, cerebro-spinal meningitis, tuberculous meningitis, puerperal fever, whooping-cough, tonsillitis.

¹ The opening paper read at a meeting of the Infectious Diseases Group of the Society of Medical Officers of Health on May 25th, 1923.

and other diseases, but I am unaware of the numbers. He had no cross infections. Dr. Rundle has treated 348 cases in his ward, and cross infection arose twice from scarlet fever and once from chicken-pox. Dr. MacIntyre treated 482 cases and cross infection arose three times from scarlet fever, once from whooping-cough, and three times from measles. Dr. Harries tells us in a letter to THE LANCET of Sept. 2nd, 1922, that he has treated 800 cases in about two years, and that on two occasions chicken-pox cross-infected and that subsequent cases appeared in the ward. He had no cross infection from measles and one from scarlet fever. I treated 497 cases, and two patients contracted scarlet fever, one mumps, five whooping-cough, one measles, and 15 chicken-pox. Table I. shows the figures:—

TABLE I.—Cross Infections.

Name.	Total cases.	Scarlet fever.	Measles	Chicken-pox.	Whooping-cough.	Mumps.
Biernacki ..	250	1	—	2	—	—
Harries ..	800	1	1	2*	—	—
Rundle ..	1348	2	—	1	—	—
MacIntyre ..	482	3	3	—	1	—
Thomson ..	497	2	9	15	5	1
Total ..	3377	9	13	20	6	1

* Dr. Harries says subsequent cases of chicken-pox arose in his ward, so I am unaware of the actual number of cross infections. He also says he gave up introducing chicken-pox in the early convalescent stage into his ward.

I have excluded the figures of Dr. Crookshank from the table as I am unaware of the total number of cases treated, and as I found no mention of chicken-pox. I have taken Dr. Biernacki's figures at a total of 250 cases in place of between 200 and 300 as given. The table is intended to show the number of bed-isolated patients only, and the resultant infections in so far as can be found. Since, as far as I know, there are no details about the work of Drs. Biernacki and Harries, Table II. is based on the results of Drs. MacIntyre and Rundle and my own only:—

TABLE II.

A = No. of cases. B = Infections.

Name.	Total cases.	Scarlet fever.		Measles.		Chicken-pox.		Whooping-cough.		Mumps.	
		A	B	A	B	A	B	A	B	A	B
MacIntyre ..	482	207	3	48*	3	26	—	25	1	2	—
Rundle ..	1348	141	2	162	—	93	1	48	—	6	—
Thomson ..	497	256	2	2	9	63†	15	75‡	5	23	1

* Includes cases infected in ward.

† Includes nine ditto.

‡ Includes two ditto.

It will be seen from Table II. that the number of scarlet fever infections is not so very different at each hospital, if one takes into consideration the number of cases of the disease admitted to each ward, and that it might be taken as offering some evidence that the technique in all these wards was about equally good. On the other hand, the evidence does not point in the same direction with regard to chicken-pox, measles, and whooping-cough. It would seem from Dr. Rundle's experience that the danger of cross infection from scarlet fever is greater than from measles, while in mine the cross infection from measles might well be considered disastrous.

Variation in Cross Infection.

An explanation, however, of these somewhat remarkable variations in cross infection at these three hospitals is very necessary, and I am disposed to believe that the chief, though not the only, explanation lies in the stages at which the diseases were introduced into the wards. Difficulty in argument arises here,

since the details supplied by Dr. Rundle are rather barren. He does not state the stage of the disease upon admission to the ward, the age-periods of his ward population, or the number of patients who were protected or unprotected. However, he states in his first published series of cases that out of a total of 42 cases of measles introduced into his ward 29 were convalescent, and out of a total of 41 cases of chicken-pox 12 were convalescent. Further, in recording his first series he tells us that a high percentage of adults was admitted. In his first series 288 cases of erysipelas, puerperal fever, and enteric fever were treated, giving a percentage of 38 of the total number of cases. In his second series full figures are not given, but evidently the percentage was lower.

There can be no question of Dr. Rundle's wisdom in attempting to lessen the danger of cross infection arising in his ward until knowledge justified taking greater risks, and indeed very great praise is due to him for his work. Now, however, that "bed isolation" has proved to be of some considerable success, it seems to me essential that it should be put thoroughly to the test before hailing it with acclamations. Further, it is also essential that all available details of the work should be published in order that others may form a reasoned judgment of the precise opportunities which existed for cross infection to arise.

If one considers the infections with which fever hospitals are most concerned—and I take these to be scarlet fever, diphtheria, measles, chicken-pox, rubella, whooping-cough, and mumps—and compares the number of these diseases with the total cases treated, one finds they comprised 43.5 per cent. of all diseases in Dr. Rundle's ward, in Dr. MacIntyre's 77 per cent., and in mine 86 per cent. As a point having some bearing on the stage of the disease at which infections were introduced into the "bed isolation" wards at these hospitals, it is of interest to note that in Dr. Rundle's ward two or more co-existing infections were present on 26 occasions only out of 1348 total cases, in Dr. MacIntyre's on 123 occasions out of 482 cases, and in mine on 143 occasions out of 497 cases. In Dr. Rundle's ward chicken-pox was co-existent with another infection seven times out of 93 cases, in Dr. MacIntyre's ward it co-existed 23 times out of 26 cases, and in mine 53 times out of 63 cases. The broad deduction from this is that very many more infections were introduced into the "bed isolation" ward from other wards in the hospital in the instances of Dr. MacIntyre and myself than in that of Dr. Rundle. To my mind this suggests that Dr. Rundle's "bed isolation" ward is fed mainly by direct admissions from outside the hospital, and it is hardly to be expected that infections from outside would be in as early a stage of the disease as those obtained from within the hospital.

I do not wish to discuss the chances of whooping-cough cross-infecting, because I quite failed to understand why infections from this disease arose in my ward, all of them during two short periods, while in a vastly longer time equal opportunities for cross infection appeared to exist without its arising. It may have been at times of a rising epidemic wave, but of that I have no particulars. I did not consider it desirable to introduce cases of measles into my ward, but two cases were admitted while incubating this disease, and both were immediately removed when evidence of measles arose. The first case infected five patients out of 11 in the ward (Fig. 1), and subsequently two tertiary infections arose. The four remaining patients all had a previous history of measles. The second case infected two others out of 11 in the ward, of whom six had a previous history of measles and five had not. These two utter failures to stop the transmission of the infection of early measles cannot be passed over without comment. If contact infection be the explanation, then the nursing must have been very bad indeed, and from my knowledge of the way in which the nursing was conducted such a lapse seems to me inconceivable. Further, had the nursing been in a state of chaos, how

comes it that other infections also present were not conveyed by contact?

Dr. Harries, in his letter already referred to, tells us that a case of measles admitted to his ward in the incubation stage initiated cross infection. Dr. MacIntyre records that when measles cross-infected in his ward several cases had been admitted three days before the eruption appeared. It would be interesting if he could tell us whether any of his cross infections were held attributable to these early introductions.

Infecting Power of Chicken-pox.

In my ward the infecting power of chicken-pox was the subject which interested me more than any other,

FIG. 1.

Showing striking distance of measles infection. Length of ward, 90 ft.; width of ward, 26 ft.

and it seems to me that chicken-pox is the ideal disease by which to test the value of "bed isolation." At its commencement it is very infectious; it is usually possible to tell with considerable accuracy whether the patients exposed are protected, for a history of a previous attack is almost always correct, though often this information is not forthcoming, but it is usually possible to find the scars if the individual has suffered from chicken-pox in the past. Further, should cross infection unfortunately arise there is no danger to life and, as a rule, but slight illness.

In so far as I am aware the average number of children in a population protected by former attacks is unknown, although some records have been worked out on history only. Dr. MacIntyre found that 26 per cent. of the cases admitted to his ward had a previous history of chicken-pox, while in my ward the percentage was 25.73. However, a history only does not disclose the number of protected with much accuracy. Every case admitted to my ward was carefully examined for chicken-pox scars, and it was found that 40.85 per cent. were protected, that 55.98 per cent. were unprotected, and that 3.16 per cent. were doubtful. Those who were admitted suffering from chicken-pox are not included in these figures, and they are therefore worked out on 443 cases. It would be interesting to know how the protection rate rises from year to year up to about 10 years of age, and Fig. 2 is an attempt to show this rise. Evidently a considerably greater number of cases would be required to show this with accuracy, for the slight rises shown at the ages of 4 to 5 and 6 to 7 can hardly be correct, and there were few patients over 9 years of age introduced into the ward. It was, in fact, my policy to introduce children into my ward at the more susceptible ages, and the age-periods of all patients were—under 5 years 52.11 per cent., 5 to 10 years 45.07 per cent., and over 10 years 2.81 per cent. The age-periods in Dr. MacIntyre's ward were—under 5 years 46.47 per cent., 5 to 10 years 40.45 per cent., and over 10 years 13.07 per cent. If at the age of 6 half the child population is protected from chicken-pox, it is a matter of the first importance to know the ages of the population in a "bed isolation" ward before conclusions of any value can be drawn.

In all the "bed isolation" wards with which I am dealing cross infection arose from chicken-pox. At Plaistow it spread to other patients on two occasions

in Dr. Biernacki's time, at Fazakerley one patient developed chicken-pox, at Birmingham it cross infected on two occasions, and subsequent cases appeared in the ward, and at the North-Eastern Hospital 15 children developed the disease. Particulars of the infectors at Plaistow and Fazakerley are wanting, but Dr. Harries tells us that his two cases at Birmingham were admitted to the ward in the incubation stage.

Diminished Danger of Infection On and After Third Day of Eruption.

Sixty-three cases of chicken-pox were treated in my ward, and of these nine incubated the disease in the ward, three were introduced on the first day of the eruption, four on the second day, 31 on the third day, seven on the fourth day, and nine on and after the fifth day. Of those who incubated the disease in the ward two arose together on separate occasions, making the actual number of exposures to this early infection seven. Of these seven exposures, five were responsible for cross infection. Of the two who failed to cross infect the first was in the ward when only three unprotected cases were present and all had already been exposed to a similar early case. The other was in the ward when six unprotected cases were present but they also had already been exposed to a similar early case. Of the three admitted on the first day the eruption one was productive of cross infection of the four admitted on the second day three cross infected, and of the 31 admitted on the third day three cross-infected. No cases of cross infection arose after the third day. For the days and distance of infection, see Figs. 3, 4, 5, and 6.

Dr. MacIntyre treated 26 cases in his ward. Of these, three were admitted on the first day of the eruption, five on the second day, two on the third day

FIG. 2.

Ward population: percentage of protection by former attack of chicken-pox in 443 patients at ages as set out (excluding 54 cases of chicken-pox introduced).

three on the fourth day, and 13 on and after the fifth day. He had no cross infection. Therefore, of cases of chicken-pox about which particulars are available, nine who incubated the disease in the ward cross-infected seven times, the six on the first day, the nine on the second day three times, the 33 on the third day three times, while the ten on the fourth day and the 22 on and after the fifth day failed to cross-infect. Dr. MacIntyre tells us that

the majority of his cases the pocks were painted daily for the first three days with a solution of picric acid. Also I think it necessary for me to say that the first 20 of my third-day cases passed through the ward without any infection arising, and that the three third-day infecting cases were all introduced during the last six months of the work, when it was becoming increasingly difficult to find suitable nurses owing to depletion of them for war purposes. I mention that point, but it is also to be borne in mind that by that time I had taken to introducing some cases early on the third day of the eruption.

It is worthy of note that ten fourth-day cases and our fifth-day cases passed through these two wards without cross infection arising, and that, from my own

FIG. 3.

Infections incubated in ward which infected others grouped together, showing striking distance of chicken-pox. 8 and 9 (bracketed) arose together. Length of ward, 90 ft.; width, 26 ft.

work on the contact infection of chicken-pox, it is early shown that contact infection of this disease can take place on the fifth day of the eruption, the contact at that occasion seeming to be indirect. It is, then, a fact that chicken-pox when introduced into a "bed isolation" ward in the incubation stage or in the early days of the eruption can cause infection in others. Further, there seems good reason to suppose that the disease is considerably more infectious if introduced before the eruption appears, and is present up to the time of outcrop of the eruption. It also seems probable that the danger of infection, if there is then danger, is greatly lessened if the case is introduced on

FIG. 5.

Second day infecting cases grouped together, showing striking distance.

the third day of eruption, and that after the third day the danger seems to cease. Why is it that the danger of infection on the third day seems small and the danger before or at the outcrop of the eruption so great?

In a paper read before the Epidemiological Section of the Royal Society of Medicine in 1912, Dr. Rundle gives as follows in favour of contact infection:—

Forty-one cases of varicella have received treatment in our 'bed isolation' ward; no instance of cross infection occurred. On the other hand, varicella has been accidentally introduced into the ordinary wards of the hospital on 21 occasions during the same period of time; cross infection occurred in every instance except one. Precisely the same

opportunities of aerial infection were present in each group of cases. How then are we to explain the striking difference in the results obtained, except on the grounds that contact infection was excluded in one series of cases only? All stages of the disease and all grades of severity have been represented in the 41 cases mentioned—in fact, more than one of them were, from the confluent character of the eruption, sent to the hospital on a mistaken diagnosis of small-pox."

I do not suppose Dr. Rundle would care to maintain that argument now. I imagine that on the 21 occasions when chicken-pox was introduced into the ordinary wards, all, or nearly all, were probably introduced before the outcrop of the eruption, while of the 41 cases in the "bed isolation" ward I do not suppose one was. If it is all a question of contact

FIG. 4.

First day infecting case, showing striking distance.

infection, how comes it that seven out of nine cases introduced in the incubation stage cross-infected, while 14 on the fourth and fifth days of the eruption did not? Very possibly the chances may be less, but we know they exist, and such a striking contrast seems to require a more satisfactory explanation than contact infection.

Cubicle and Cell Wards.

Then we have evidence that it is unsafe to treat chicken-pox in cubicle and cell wards which have internal means of communication between the cubicles or cells. I have had experience of three

FIG. 6.

Third day infecting cases grouped together, showing striking distance.

cubicle and two cell wards, all with internal corridors, for 17 years, and I have found it unsafe to introduce into any of them chicken-pox in its earliest stages. I have found that if a patient incubates the disease in a cubicle ward cross infection is usual, and that cross infection under similar circumstances is not uncommon in cell wards. On the other hand, I have a ward with single rooms, the door of each opening to the outer air on to a verandah, but with no internal communication between the rooms. This ward is used for the treatment of chicken-pox as well as other diseases, and a large number of chicken-pox cases have passed through it, many of them incubating the disease there, but cross infection to other rooms

has been very rare. The opportunities for contact infection in this ward are as great as in my cubicle or cell wards, or as they were in the bed isolation ward, but there is all the difference in the resultant cross infections. Personally, I consider it wise to remember that our knowledge of the manner in which infection is transmitted from one person to another in a ward is incomplete, and that it is unwise to speak of infection being conveyed by contact only, or by droplets in the immediate surroundings of the infector.

Conclusion.

In my experience "bed isolation" can do a great deal in the prevention of cross infection, and in certain circumstances is a most useful method of isolation. But the statement of THE LANCET that "bed isolation" is a system which makes it possible for any sanitary authority to treat within small compass all the infectious diseases in the area which need special care, leaves me lost in wonder. It is a statement which might well be made effective use of by lay councillors, to evade the provision of proper isolation accommodation, and in the light of our present knowledge is unjustifiable.

Before concluding, I would like to refer to the interesting work of Drs. A. F. Cameron and B. A. Peters, on aseptic nursing in a general fever ward, and to express a hope that we may hear more about that method of lessening the danger of cross infection.

THE TREATMENT OF DIABETES MELLITUS WITH INSULIN

AND CARBOHYDRATE RESTRICTION.

BY GEORGE GRAHAM, M.D. CAMB.,
F.R.C.P. LOND.,

AND

C. F. HARRIS, M.B., B.S. LOND.

(From the Wards and Laboratories of the Medical Unit, St. Bartholomew's Hospital, London.)

THE introduction of insulin in the treatment of diabetes mellitus has raised many new problems, and among them that of the best method of using it. Most of the work has been done on patients with a severe form of the disease, since if good results can be obtained with them it is certain that equally good results will be obtained with patients who have only a mild form of the disease.

Two severe cases and one milder one have been treated in the wards of the Medical Unit at St. Bartholomew's Hospital, and have all been investigated according to the following plan. A diet was given consisting almost entirely of protein and fat, but including 16 g. of sugar in the form of vegetables; the caloric value varied according to the condition of the patient. A dose of insulin was given once a day, or very occasionally twice a day. No extra carbohydrate was given until the blood-sugar before the insulin injection had been below 0.12 per cent. for a considerable number of days.

Clinical Records.

CASE 1.*—A man, aged 26, who had diabetes for three years and had become steadily worse in the last year in spite of careful treatment on modern lines. In December, 1922, he was admitted to this hospital, under the care of Dr. H. Morley Fletcher, being very ill with some symptoms of impending coma. However, he improved considerably under treatment with starvation and gradual increase of food (no added carbohydrate) but always passed sugar in the urine. After four weeks he was discharged as a hopeless case, but was readmitted to the wards of the medical unit, under Prof. F. R. Fraser, as a suitable subject for the trial of insulin.

In spite of two hunger days, two egg and vegetable days, and two more hunger days, he continued to pass a small amount of sugar in the urine and the blood-sugar on the morning after the fourth hunger day was still 0.20 per cent. The diet was then gradually increased up to protein 53.2 g.,

fat 109.5 g., and 16 g. sugar in the form of vegetables; caloric value 1260. The amount of sugar excreted varied between 25 and 33 g. per day, although the total sugar available in the diet was 16 g. from the vegetables and 27.5 g. from protein = 43.5 g. The amount of aceto-acetic acid varied from 1.0 to 1.6 g. reckoned as acetone. The blood-sugar at about 9 A.M. varied between 0.25 per cent. and 0.20 per cent. This preliminary period of observation lasted

FIG. 1.

Effect of insulin on blood-sugar.

for 16 days. The insulin was usually given about 9 A.M. immediately after the morning blood-sugar had been collected. The initial dose given was only 1 1/2 units (no style) and was gradually increased up to 9 units. The dose always caused some fall in the blood-sugar (Fig. 1), but the first time the urine was only free from sugar from 12 noon to 3 P.M., then from 12 noon to 6 P.M., and after 11 days the urine passed at 6 A.M. only contained a trace of sugar, though

FIG. 2.

Effect of insulin on blood-sugar.

the urine from 6 A.M. to 9 A.M. still contained a little sugar. On the twelfth day no sugar was excreted at all, and more sugar was excreted except once, when no insulin was given for two days, and once when he had a swollen leg after the injection of some insulin which had become infected and was given in error (Fig. 2).

On the thirteenth day the blood-sugar was estimated two-hourly intervals throughout the day and part of

FIG. 3.

Fall of blood-sugar after 9 units on thirteenth day and after 3 units on fifty-first day.

following night (Fig. 3). The usual meals were eaten at 6 A.M., 9 A.M., 12 noon, 4 P.M., 7 P.M. The fasting value of the blood-sugar was 0.195 per cent. and 9 units of insulin were injected immediately after the blood had been collected. The blood-sugar fell to 0.085 per cent. after six hours, was still at 0.12 per cent. 10 hours after the injection, had risen to 0.17 per cent. after 12 hours and to 0.20 per cent. after 16 hours, but fell to 0.185 per cent. at the eighteenth hour, while at 6 A.M.—i.e., 24 hours after

* Case E. Report to Medical Research Council.

dose—it had fallen to 0.17 per cent. Only 0.38 g. aceto-acetic acid (as acetone) were excreted instead of 1.6 g. before the insulin was started. The aceto-acetic acid was estimated every two hours, and the hourly output fell abruptly after the insulin injection, but rose again as soon as the blood-sugar rose above 0.17 g. (Fig. 4).

There are two points of great importance in this experiment: (1) The time taken (6 hours) in reaching the lowest point, and (2) the fact that the maximum

FIG. 4. Showing hourly output of aceto-acetic acid as acetone after 9 units of insulin on thirteenth day.

se in the blood-sugar took place 16 hours after the use of insulin. Presumably all the effect of the insulin had passed off by this time, as the aceto-acetic acid output had increased at the fourteenth hour, and the patient was then left to work with that which could produce himself. (3) That the blood-sugar increased from the sixteenth hour to the twenty-fourth hour, when it is probable that the patient was dependent on his own insulin. In view of this result we decided to make no alteration in either the diet or the dose of insulin in order to see whether the morning value of the blood-sugar would continue to increase.

On the thirtieth day the morning value of the blood-sugar reached 0.15 per cent. for the first time and remained about

FIG. 5. Effect of insulin on blood-sugar. On the twenty-fifth day the insulin was sprayed into the post-nasal space.

s level for the next two days (Fig. 5). On the thirty-fourth day 50 g. of butter were added to the diet, making a caloric value of 1620. On the thirty-fifth day the dose of insulin was reduced to 3 units, as 9 units had lowered the blood-sugar to 0.06 per cent. three hours after the injection. The morning blood-sugar again rose above 0.15 per cent., so the dose was increased to 8 units on the fortieth day (Fig. 6). On the forty-seventh day the morning blood-sugar had fallen to 0.12 per cent., and the dose was again reduced to 3 units. On the fifty-first day the blood-sugar was again estimated at two-hourly intervals throughout the day (Fig. 3). The morning blood-sugar was 0.115 per cent. and was not detected above 0.12 during 14 hours. On the fifty-second day 25 g. of meat and 25 g. of bacon were added to the diet—caloric value 1838—without causing any appreciable increase in

the blood-sugar. On the sixty-third and six subsequent days no insulin was given, and the morning value of the blood-sugar varied between 0.105 and 0.125 per cent. On the sixty-eighth day (Fig. 7) it did not vary more than from 0.10 per cent. to 0.13 per cent. when the blood was collected at two-hourly intervals throughout ten hours of the day. Since the morning value of the blood-sugar had now been

FIG. 6. Fall of blood-sugar after insulin. at a normal level for 18 days and during the last six days no insulin had been injected, it was thought justifiable to add bread to the diet and still withhold the insulin. Therefore 10 g. of bread were given on the sixty-ninth day and the blood-sugar was estimated at 30-minute intervals. No rise was observed in two hours, and the same was the case after 20 g. On the seventy-third day 40 g. of bread were given (Fig. 8), and after this amount the blood-sugar rose from 0.11 per cent. to 0.17 per cent. after 60 minutes, and after 90 minutes was still 0.165 per cent. On the seventy-fourth day 8 units of insulin were given 30 minutes before the 40 g.

FIG. 7. Blood-sugar on sixty-fifth day, when no insulin was injected.

of bread. The blood-sugar was 0.16 per cent. after 30 minutes, but had fallen to 0.145 per cent. after 60 minutes; it was still at this level after 90 minutes, but had fallen to 0.12 per cent. after 120 minutes. Since this rise is greater than that which occurs in normal individuals after this dose of bread, it was decided to give 8 units of insulin each day 30 minutes before the bread was eaten. On the seventy-eighth day the caloric value of the diet was increased to 2020 by the addition of 25 g. of ham and 100 c.cm. of milk. On the eightieth day the blood-sugar was estimated at 30-minute intervals after the 40 g. of bread but no rise was detected, although no insulin had been injected (Fig. 8).

FIG. 8. Effect of blood-sugar after 40 g. bread on different days.

The bread was therefore increased to 80 g. by 10 g. doses, and 8 units of insulin injected daily. On the eighty-seventh day (Fig. 8) no insulin was given, but no sugar was excreted after 80 g. bread. On the ninety-eighth day a dose of 25 g. of sugar (no insulin) sent the blood-sugar up to 0.18 per cent. after 60 minutes, and at the end of 120 minutes it was still at 0.20 per cent. No sugar was excreted in the urine in the first hour, but 0.9 g. was excreted in the second

hour. This last experiment shows that although a big recovery of tolerance has taken place, the sugar tolerance is still low.

The patient's general condition has greatly improved. He has been kept in bed all the time, as is our usual custom, partly because patients with severe diabetes do better if they are at rest in bed, and partly because it is much easier to control the diet of a patient in a general ward, since it reduces the risk of a patient adding carbohydrate to the diet. The actual gain in weight is rather difficult to assess, since, like many patients with very severe diabetes, he developed a great deal of oedema, gaining 13 lb. in ten days just before the insulin was started. Since he lost the oedema and settled down to a steady weight he has gained 6 lb. Both the knee- and ankle-jerks were completely absent on admission, but they have all returned now.

CASE 2.†—A man who had had diabetes for over three years was admitted to hospital under Dr. J. H. Drysdale in a condition typical of diabetic coma except that he was just conscious. He complained of severe abdominal pain and the eyeball tension was very low. There was well-marked air hunger and the movements of the abdomen and chest were extreme. The percentage of carbon dioxide in the alveolar air was 1.18 instead of over 5 per cent. and the blood-sugar was 0.33 per cent. A dose of 15 units of insulin was given, and three hours later the blood-sugar had fallen to 0.19 per cent. and the alveolar carbon dioxide

Fall of blood-sugar and rise of alveolar carbon dioxide in a case of diabetic coma after 15 units of insulin.

had risen to 1.7 per cent. The general condition had greatly improved; the abdominal pain had disappeared and the air-hunger was noticeably less. In six hours the blood-sugar had fallen to 0.11 per cent. and the alveolar carbon dioxide had risen to 2.7 per cent. (Fig. 9). We were prepared to give sugar, together with another dose of insulin as well, if the patient's condition had not improved so rapidly. The amount of sugar excreted between 12 noon and 10 P.M. was 18 g. and the night urine contained no sugar. The amount of aceto-acetic acid excreted in the same period was 0.7 g. and was very small in amount in the night urine. The usual treatment for a severe diabetic was given in the next few days, together with 16 units of insulin. During the two hunger days and two egg and vegetable days—caloric value 478—the morning blood-sugar was between 0.23 and 0.27 per cent. (Fig. 10), but when 50 g. of meat were added—caloric value 608—the morning blood-sugar rose to 0.35 per cent. Consequently on the eighth day another hunger day was given, together with 20 units of insulin in the morning and 10 units at 4 P.M. The blood-sugar fell to 0.08 per cent. in nine hours and had not risen above 0.14 per cent. the next morning; no sugar was excreted in the urine the next day and there has been none since. On the ninth day a hunger day was also given together with 9 units of insulin in the morning and 3 units at night. On the tenth and eleventh days, eggs and vegetables (no butter) were given—caloric value 478—together with 9 units in the morning and 3 units at night. On the twelfth day 50 g. of meat were added—caloric value 608—and on the fourteenth day the morning blood-sugar was 0.125 per cent. After this day only one dose of 8 units was given each day and the blood-sugar rose again to about 0.15 per cent. On the eighteenth day the diet was increased to 778 calories by means of ham, and on the twenty-first day to 900 calories by means of bacon; on the twenty-eighth day to 1264 by means of butter. The morning blood-sugar had remained about 0.15 per cent. all this time, and as it did not seem to be decreasing the dose of insulin was increased to 12 units; and on the forty-second

day the blood-sugar at last came down to a normal figure. The diet was increased to 1260 calories on the forty-second day and to 1838 on the fiftieth day. The blood-sugar is usually below 0.10 per cent. in the morning. On the seventy-second day a dose of 40 g. of bread (no insulin) sent the blood-sugar up to 0.17 per cent. after 60 minutes, and it was still at 0.165 per cent. after 120 minutes. No sugar was excreted in the urine in the first hour, but 0.2 g. was excreted in the second hour.

It is proposed to keep the diet free from extra carbohydrate for another 14 days and then gradually add bread, keeping the dose of insulin about 8 units.

Effect of insulin on blood-sugar. The dot indicates the blood-sugar before insulin, the cross indicates the blood-sugar after insulin. The numeral below or beside the cross represents the number of hours after the giving of insulin.

CASE 3.—This man had a much milder form of the disease as on the ordinary severe dietetic restrictions in use in this hospital he ceased to pass any sugar, and the morning blood-sugar was 0.16 per cent. on a diet of protein 53.5 g. fat 109.5 g., sugar as vegetables 16 g., calories 1260. The progress was at first unsatisfactory, as he became very anæmic, hæmoglobin 30 per cent., as the result of bleeding from hæmorrhoids. These were removed after a small blood transfusion of 300 c.cm. had been given. He stood the operation quite well, and is rapidly regaining strength. He has further complicated the experiment by adding unauthorised carbohydrate to his diet at odd intervals. In spite of these setbacks he now has a normal blood-sugar on a diet of protein 53.2 g., fat 149.5, sugar 16 g., calories 1622. It is proposed to add carbohydrate cautiously to the diet giving 8 units of insulin each day. The patient has twice had slight symptoms of over-dosage, as he sweated and felt very limp for about 30 minutes some three hours after a dose of 10 units of insulin. The blood-sugar was on 0.06 per cent., whereas both the other men have had a fall of blood-sugar to 0.05 per cent.

Remarks.

The treatment of these three patients with small doses of insulin on a diet of low caloric value and on 16 g. of sugar differs from that which has been used by Banting² and his co-workers and the other workers in this country.¹ The usual plan adopted has been to give insulin two or three times a day together with a certain amount of carbohydrate. The improvement which takes place in the clinical condition is very great under these conditions. The patient feels better and rapidly gains in weight and strength. Some of these patients do pass a little sugar each day before the insulin is given, and the blood-sugar may be considerably over 0.20 per cent. It seems certain from the previous work on experimental diabetes in dogs by Allen³ that the β cells of the islands of Langerhans, which control the level of the blood-sugar, can be overworked by overfeeding either with sugar or starch. Under these circumstances Allen showed by examining sections of the pancreas taken at frequent intervals that the β cells first lose their granules, then develop a vacuole; the nucleus is pushed to one side and the cell may break up altogether. If, however, the overfeeding with sugar is stopped, and the animal is starved, Allen is inclined to believe, although, as he says, it is very difficult to be certain, that the β cells may recover, the vacuole disappearing, and the granules reappearing.

† Case G. Report to Medical Research Council.

Further, the whole of the recent advances in treatment of patients by starvation or underfeeding has been based on the belief that in this way the β cells might be rested and allowed a chance to recover. The aim has been to reduce the fasting blood-sugar to a normal level. Hence it seems probable that whenever the blood-sugar is above 0.20 per cent. the β cells are being overworked. It is also probable that whenever the fasting blood-sugar is above 0.13 that there is some degree of overstrain. And it is also conceivable that the β cells may be working their utmost in order to keep the blood-sugar normal (0.12 per cent.) and are therefore overworking. The use of insulin will, however, enable the cells to be thoroughly rested for a long time, and if they are capable of recovering under these conditions there should be an increase in sugar tolerance. From our experiments it would seem that it is necessary to lower the blood-sugar below 0.10 or even 0.08 per cent. each day, so as to give no work to the β cells if possible. If this view is correct it is inadvisable to give any carbohydrate until the blood-sugar has been at a normal level for a considerable time.

It is still much too early to speak with any real certainty, but if the two patients in this series with severe diabetes keep well and continue to improve, and if other patients also behave in the same way, it would appear that, provided too much destruction has not taken place in the initial attack of the disease, there is some chance that the surviving β cells of the islands of Langerhans may recover their full activities. If this should prove to be the case, then it must mean there were a sufficient number of β cells which were only exhausted and not destroyed.

Banting, Campbell, and Fletcher state that certain cases, after a period of insulin treatment, recover such a degree of tolerance that insulin is no longer necessary to maintain them on their basal diet. Unfortunately, only one case is quoted and no figures for the blood-sugar are given. Still, this statement does support the experience which we have had so far.

Maclean,⁴ on the other hand, has stated that "in long-established cases he has seen no sign of increase of tolerance after insulin and should doubt whether in such cases much is to be hoped in this direction." Maclean has, however, used much larger amounts of carbohydrate—30–40 g.—in addition to the sugar in the vegetables. Further, he does not say in his paper that he aims at keeping the fasting value of the blood-sugar within normal limits. These are, we believe, essential points in the treatment, and may well account for the failure of Maclean's patients to recover sugar tolerance although their general condition was greatly improved.

In order to treat patients on the lines which we have used it is essential that a certain number of determinations of the blood-sugar should be made, though it will be quite unnecessary to do so many as we have done in learning the method. We suggest that the patient should be treated at first with the usual method of two days' starvation in order to get the urine sugar-free, if possible. Whether this is successful or not the diet should be gradually increased to about 1260 calories, made up of protein and fat, with 16 g. sugar in the form of vegetables. The blood-sugar should then be determined in order to gauge the dose of insulin required. If the blood-sugar is normal a dose of 5 units may be safely ordered for an adult; if it is higher than 0.13 per cent. a dose of 10 units can probably be given in safety. On the next day the morning blood-sugar should be determined (but this may be omitted), and the blood-sugar again determined four to six hours after the insulin injection. If the blood-sugar falls below 0.10 per cent. and no unpleasant symptoms occurred, it may be assumed that the dose is a suitable one. If the blood-sugar does not fall so low as 0.10 it is probably better to make no change for another seven days. Then the blood-sugar before and four to six hours after the injection should again be determined. If the blood-sugar has now fallen below 0.10 per cent. the dose may be considered as suitable.

If the blood-sugar has not fallen low enough the dose should be increased. Afterwards the blood-sugar should be determined before the insulin injection at least once a week or fortnight until it falls to normal. The dose should be diminished if any symptoms of overdosage occur, and in our limited experience if this method is employed no startling symptoms will appear. After the blood-sugar has fallen to normal the caloric value of the diet can be increased and bread gradually added. In severe cases the process of recovery of tolerance must be a slow one, but in mild cases it is to be hoped that it will be much more rapid, but of this we have no experience.

Insulin should not be regarded as a mere substitute (like thyroid extract for the treatment of myxedema) for that usually formed in the β cells of the islands of Langerhans, although it can be used in this way, and 10 units of insulin at the cost of 2s. 6d. will suffice for the correct usage of 20 to 30 g. of sugar. It should rather be regarded as a valuable remedy which will relieve the overworked β cells of as much work as possible and perhaps enable them to recover some of their functions.

It is with some diffidence that we have decided to publish a preliminary account of the method which we have been using, since we cannot report more than the early history of these patients, but the after-history will be reported later whether it be good or bad. Further, we may have been very fortunate in the patients we treated, and other patients with severe forms of the disease may not respond to treatment so well. However, we thought that it was justifiable to publish the method so that it may be tested by other workers.

Conclusions.

1. If our view is correct, and if the best possible results are to be obtained, it is unwise to give any carbohydrate at all, except that in vegetables, until the fasting value of the blood-sugar has been below 0.12 per cent. for some considerable time.

2. It would also appear from our figures that in order to produce this result the blood-sugar must fall well below 0.10 or even 0.08 per cent. each day in order to relieve the β cells of the islands of Langerhans of as much work as possible. It may be necessary to aid this by somewhat rigorous dietetic restrictions, as in Case 2, or it might be achieved by giving larger doses of insulin.

3. An advantage of our method is that only one dose of insulin a day is required, and the dose is much smaller.

4. The disadvantages are: (a) The comparatively slow progress of the patient; (b) the careful watching of the blood-sugar which is required, at any rate at the beginning of the treatment; (c) the necessity of lowering the blood-sugar each day below 0.10 or 0.08 per cent. and so running some slight risk of causing unpleasant symptoms if the blood-sugar falls too low; (d) the tendency of all patients with severe and long-standing diabetes under severe dietetic restrictions to steal carbohydrates and so delay the fall of the blood-sugar to normal.

We have to express our thanks to Prof. F. R. Fraser for permission to work on his patients and for his constant assistance; to the Medical Research Council for permission to make the insulin and for its grant towards the laboratory expenses; to Dr. H. H. Dale and Dr. H. W. Dudley for the full details of the manufacture and for much help; to Dr. W. H. Hurley, in whose laboratory the insulin was made, and for his advice and help with its manufacture; to the laboratory assistant, Mr. A. F. Colson, who has latterly carried out the manufacture of the insulin, and especially to Miss V. Etches, the ward sister, for her constant care in supervising the patients and their diet.

THE TECHNIQUE OF BLOOD-PLATE COUNTING IN MAN.

BY R. G. BANNERMAN, M.D. EDIN.,
ASSISTANT MEDICAL OFFICER, ENGLISH SANATORIUM,
MONTANA, SWITZERLAND.

A DIRECT count of blood-plates seems to be impossible owing to their disposition to adhere to one another and to foreign bodies, such as glass, when the blood is shed. It is therefore necessary to determine by a special procedure the proportion of red corpuscles to plates, and then, the red corpuscles having been counted in the usual way, to calculate the absolute number of plates. The large number of the methods that have been used by different observers testifies to their unsatisfactoriness and difficulty. The following method contains elements of various others, and is described because it has yielded the most consistent results; but it is well recognised that the ideal has not yet been reached.

Method of Puncture.

The best site of puncture for blood is the back of the finger proximal to the nail bed, where the skin is thin, and the tissue vascular yet firm; a thin layer of paraffin is left on this part by touching with a hot glass rod first a block of paraffin and then the finger. Two sharp surgical needles are first heated in their middle and then run through the edge of the paraffin block, so that the points are layered with paraffin yet do not have their temper destroyed in the flame. A droplet (of about 2 mm. diameter) of the diluent, freshly filtered, is then placed on the paraffined area of the finger. The composition of the diluent is as follows:—

Sod. metaphosphate ..	0.2	Formalin ..	2.0
Sod. chloride ..	0.9	Distilled water ..	100.0

The solution is lightly tinted with methylene-blue. Sodium metaphosphate (following Pratt) was found to be superior to other substances tried in discouraging agglutination, and the formalin preserves the plates and corpuscles in such a way that reliable counts may still be made many hours after the preparation was set up.

Slides and coverslips are cleaned in the usual way. The skin is punctured through the droplet of diluent by a sharp prick of one of the needles; a slide is quickly lifted and its centre lowered on to the droplet and then raised so as to bring away blood and diluent; the second needle having been used to stir them into a homogeneous mixture, the slide is lowered in the inverted position on to a coverslip, which is then immediately sealed on to the slide with melted paraffin. These stages all demand rapidity of action, and sharpness of the needle is of the utmost importance. If there be not an immediate and sufficient flow of blood, or if the flow be excessive, that puncture must be abandoned and another attempt made. If there be too much blood in the mixture, the mistake cannot be rectified by wiping off some of it, nor by pressure on the coverslip; such procedures were found to disturb the relative proportions of plates and red corpuscles.

Discrepancies Resulting from Errors of Technique.

Table I. shows counts all made about the same time from the same subject and illustrate the discrepancies that result from errors of technique:—

TABLE I.

	Notes.	R.B.C. per plate.	R.B.C.	Plates.
1	Rapid flow	18.6	5,100,000	274,000
2	Rapid flow	17.5		297,000
3	Slow flow	29.2		175,000
4	Intentionally slow flow ..	34.9		146,000
5	Rapid flow; excess of blood; "wipe off"	15.3		333,000

The plates are easily detected by reason of their faint blue coloration, their Brownian movement, and their characteristic structure. The counts were made

with a 1/12-inch oil immersion objective, a No. 4 eye-piece containing a square diaphragm, and a draw-tube at a known length; with the optical system used there is an optimum concentration of blood to be aimed at. In this case it was found to be such that each field contained between 20 and 30 red corpuscles; fields not meeting this condition were rejected, since it was shown by prolonged differential counts in the same preparation that if the number of red corpuscles in the field were fewer than 20 the proportion of plates was unduly high, and the contrary was the case if the red corpuscles exceeded 30 to the field.

Table II. shows counts from two preparations which were made at the same time from the same subject:—

TABLE II.

	Average number of red corpuscles per plate in fields containing—			Average 14.3 14.8
	10-19	20-29	30-39	
1	9.9	14.7	18.2	
2	9.7	15.2	19.5	

It will be noticed that the grand average approximates to the figure given by the 20-29 class of field; this has been an invariable experience, and it was concluded that such fields, as giving the most representative counts, were of the optimum concentration, and ought to be selected to the exclusion of others. There are probably physical reasons for these anomalies of distribution, and the admission must follow that the figures obtained, though legitimately comparable, may not be strictly absolute.

Method of Counting.

In practice it was found desirable to make, for each observation, two preparations, and to count in each at least 40 plates and the accompanying number of red corpuscles; the number of red corpuscles per plate can thus be determined, and if the preparations satisfy the requirements above described, the numbers obtained from the two preparations should not differ by more than 10 per cent.; the average of these two figures divided into the number of red corpuscles per c.mm. gives the number of plates per c.mm. It is sometimes possible to reduce an excessive experimental error by counting a further series of fields in a different area. Practice and uniformity of technique are essential.

Table III. gives some idea of the kind of results obtained; all are from the same subject, and the increase of plates on one occasion (Nov. 28th, 1922) is an example of a physiological variation to be reported upon later.

TABLE III.

Date in November, 1922.	R.B.C. per plate.	R.B.C.	Plates.	Approx. per cent. difference.
25th ..	(1) 23.8 (2) 25.2	5,680,000	237,000 222,000	7
26th ..	(1) 23.8 (2) 22.9	5,690,000	237,000 246,000	4
27th ..	(1) 23.0 (2) 22.8		245,000 247,000	1
28th ..	(1) 17.0 (2) 15.9	5,600,000	331,000 354,000	7
29th ..	* (1) 22.3	5,540,000	252,000	—
—	Average ..	5,630,000	—	—

* Single observation.

There being no significant variation in the number of red corpuscles, the average of four counts was used in calculating the absolute number of plates.

I wish to express my thanks to Prof. Hector Christiani, of Geneva, in whose laboratory the work was started; to Dr. P. Gautier, also of Geneva; to Dr. W. Cramer, of the Imperial Cancer Research Fund, who suggested the subject; to Dr. Bernard Hudson, of the English Sanatorium, Montana, who freely provided material and opportunities; and to the Medical Research Council, who gave a grant in aid of this research. The investigation has been carried on during the tenure of the McCosh Bursaries (University of Edinburgh, 1914 award).

DUAL PERSONALITY.

By ROBERT M. RIGGALL, M.R.C.S. ENG.

A TRUE splitting of personality should be distinguished from a fugue, although psychologically both can be classified as dissociations. A dissociated state is simply the manifestation of the repression of some unpleasant experience which, instead of remaining quiescent, has acquired independent activity. A case of dissociated personality is by no means an isolated curiosity. It differs only in the mode of manifestation from quite common cases of wandering, loss of memory, sexual manias, and alcoholism or drug attacks. All are manifestations of some repression of unpleasant experience; accident and temperament usually determine the mode of manifestation; the essential fact is that by losing himself in the "unconsciousness" of drugging and kindred manias or by dramatising himself into some other personality, as my patient did, the subject for a time gets rid of the burden of his neurosis. A fugue takes on more the character of the type induced by narcotics. When the normal state of consciousness is resumed the patient has amnesia for the incidents taking place during the fugue; these incidents can only be revived by psycho-analysis or hypnosis.

As the late Dr. W. H. R. Rivers pointed out, the subject of a fugue is not unconscious but quite capable of experiencing all the modifications of consciousness open to the mind in its normal state. This particular state of consciousness is simply cut off from the normal waking life of the subject.¹

The case I am about to describe shows this dissociation in a more marked degree than in the common condition of fugue. Morton Prince, in his description of Miss Beauchamp, has described a case of multiple personality in which one of the personalities was able to control the others. He prefers to use the word "co-conscious" rather than unconscious for this type of case. In the ordinary fugue there is no independent consciousness at all; the unconscious has not personified. My case is simpler than Morton Prince's in that I was unable to discover more than one separate personality; but it differs from the ordinary fugue in that the patient dramatised his unconscious state.

The Case Described.

History.—The patient has been under my observation at intervals for three years. He is the youngest of a family of ten; two of his sisters are engaged in religious work, one with a missionary society in India, the other with the Church Army in England; a brother—the alter ego of his dissociation—was training as a missionary but enlisted in the army on the outbreak of the war and was killed. The father, who was a policeman, was a very strict disciplinarian; the mother idolised her youngest child and always protected him from his father's sternness. Between him and the brother B., who was only two years his senior, was a very strong bond of affection. There is no history of infantile convulsions or of petit mal. As a boy the patient was abnormally sensitive to suffering and cruelty; experiences of his fourth year revived under hypnosis relate to his father's sternness, his mother's soothing; later recollections tell of his fondness for reading books of adventure and travel, particularly books connected with running away to sea. In fact, before the war he became a ship's steward, but subsequent experience has shown that his attacks of wandering have nearly always followed a visit to the seaside. Unfortunately not very much can be gathered about his first "nervous breakdown," which occurred before the war, when he was 18. But four years' experience have convinced me that there is very little "war shock" proper. The stress of war conditions has simply revived latent conflict; in most cases by the defensive intensifying of the instinct for self-preservation which had been repressed, along with a multitude of associations and conflicts, in the course of growth and education; whereas the mass suggestion of war, in some cases, released latent primitive savagery, in other cases it released conflict just as atavistic in the history of the individual as is savagery in the history of the race. The patient is married and has three children. His army record shows that he enlisted in May, 1915, and served in

Gibraltar and Egypt; in April, 1916, he was transferred to France, where in June of the same year he was blown up and sent to hospital in England. He remained in hospital until the following May; in October, 1919, he was brought before a medical board after having been found wandering and taken to a workhouse for refuge. He was first seen by me on Sept. 16th, 1920, and continued under my treatment until Jan. 19th, 1921. I then thought that I had fused the dissociated personality and was able to get him taken back at his previous employment. He came back to me on Oct. 16th, 1921, after an attack of wandering at Fleetwood. I found him intelligent and suffering from no apparent signs of anxiety; he was quite unable to recall details of his wanderings during his periods of amnesia, but under hypnosis he described them very clearly.

Attacks of Wandering.

First Attack of Wandering.—I have received from the patient a written account of his first attack of wandering, which happened when he was with his battalion at Shoreham in October, 1916. It was during this month that he heard of his brother B.'s death in France. At the time he was very much worried by his family's opposition to his marriage; his mother, to whom he was devoted, had told him that he would tire of his fiancée in a month and he was in severe conflict between his respect for his mother's opinion, his own desires, and his duty to his fiancée. Also his hypersensitive nature seems to have suffered severely from the coarse and suggestive chaff of his army companions on the subject of marriage. It was then that he felt compelled to be alone and think things out for himself, for he felt that his senses were leaving him. Leaving camp he walked to Brighton, and knew nothing more until he wakened in hospital, where he was kept for five weeks. He was next sent to Springfield War Hospital, where his progress was good except for attacks of hysteria. After his discharge he went to the dépôt at Ealing, after which he worked as a clerk in Woolwich Arsenal. In 1919 he came under the influence of Mr. P., a Baptist minister, who had at first a peculiar attraction for him and persuaded him to help in a boys' brigade. Mr. P. was the object of the patient's transference of emotions connected with the "stern father" of his youth. With him the patient had much argument about death, the clergyman taking the extremely orthodox views of his sect; for instance, he tried to make the patient believe that a man who died with an oath on his lips would have to answer for it in the next world; that a man responsible for another's death would be punished after his own death, and so on: this religious conflict was very severe and brought back dreams of the days of active service which the lapse of time and the patient's morbid imaginings had intensified in horror.

Second Attack.—During this period he felt that if he could find his brother B. his troubles would be over; the typical neurotic's desire, the quest for the unattainable which, if attained, would bring rest and peace; if not attained is excuse for relapsing into the neurotic state. Whether he consciously wished to find his brother because B. was dead, and therefore his finding him would presuppose his own death and consequent cessation from conflict, or whether he felt that B., being a theological student, might have some inside information on his religious doubts, direct from the throne of Heaven, as it were, is not very clear. Changes at the office had been greatly worrying him; Mr. P. was urging him to try "Faith Healing" or "Divine Healing" and advised him to give up his treatment; he also advised him to give up living with his wife for a time. In the midst of this conflict he went with his wife and children to Bournemouth for the summer holiday, where, he records, they were very happy. On his return he was delighted to find a letter pointing the way to a better position, which would have meant his leaving irritating office surroundings; it is interesting at this point to note that his unhappiness at the office arose from what he considered the petty tyranny of a woman superior. On learning that this letter had come to him by mistake his disappointment was so severe that he experienced all his old mental torments and for two nights had no sleep. An interesting fact emerges here. I interviewed the patient's wife, who told me that after a happy seaside holiday he was "always upset." She associated the upset with the sea. Yet before his first splitting he had been happily at work as a ship's steward. Examination of his history since the splitting reveals the fact that he was always "upset" after a particularly happy time with his wife; the upper working-class summer holiday, a lazy time at the seaside with something of the return to honeymoon days when the man is released from his office, the woman from her kitchen, and they can devote themselves to each other. Here, again, is the typical neurotic picture; when things go too smoothly for a neurotic he gets dissatisfied and "looks for trouble." In this case the conflict was between his repressed, unconscious homosexuality and the pleasure he took in heterosexuality; he was distressed because he had

¹ Instinct and the Unconscious, Cambridge University Press.

found pleasure in his wife's company and thus, as it were, was untrue to a vague, intangible ideal repressed into the unconscious and from that vantage-point dominating his whole being; such a neurotic is in the condition of a man who receives messages by wireless delivered with such an air of authority that they must be obeyed, although he has no notion whence they come. Peace can only come when this "authority" is dethroned.

On this particular occasion, instead of going to work, the patient took train to South Harrow and wandered aimlessly about until he found himself on a hill down which, many years before, he had cycled with his dead brother. He had been in severe conflict all morning, turning to go home at one minute, impelled onwards the next; at this point the conflict gave place to a sense of expectancy. He lived again the ride down the hill when his brakes failed to act, and B., standing at the foot of the hill, had caught him as he crashed into the brickwork of a bridge just in time to save him from an oncoming omnibus. Here B. was waiting for him as before, and they were joined by the elder brother F., who had been killed in Canada many years before. They walked on together, being uncertain which path to take; personally, he wanted to go to Tring, which he felt promised peace and rest. But by degrees the personality of B. so took possession of him that he was impelled to set out for Burgh in Lincolnshire, where B. had been training at a missionary college; he felt that he must carry on B.'s work there. He walked about until he dropped, when he was taken to Hemel Hempstead Infirmary. On reviving these experiences under hypnosis his anxiety was severe; he begged his brothers not to pull him about. I had to waken him.

Other Attacks.—Another time he was found wandering on the Island of Skye, where he had walked into the sea. After a detailed description of the journey to Inverness, involving many changes, he stated that the Island of Skye on a railway map on Crewe station appealed to him as a far-away place where he might find peace and rest; heaven, the heaven of his childhood's teaching, "above the bright blue sky," might possibly be there! After wandering about the hills at Strom Ferry, he decided that "that was not the place he was looking for," but, seeing some men going in a boat to the island, he begged them to take him. It seemed to be the "place he was looking for." On landing he wandered about miserable and lonely, wishing himself at home. Then he made a consciously determined, but unconsciously self-defensive, effort at suicide in order to get back to the pre-natal state of oblivion. That is, he tied his hands with a strap—knowing himself to be a strong swimmer—but unfastened the strap in order to write a letter of explanation to his wife. After this, failing to find the strap again, he weighted his pockets with stones and walked into the sea. There the shock of the cold water, when he had walked out of his depth, brought him to himself; relieving himself of the stones, he swam to land, where he found care and attention from the villagers and the Poor-law officer.

At another time, under hypnosis (Oct. 22nd, 1921), the patient gave minute details of office work and various accounts and invoices that worried him. In this instance he took an omnibus to King's Cross, in severe conflict because he wished to kill his wife. A few moments later he was so anxious about his wife's welfare that he longed once more to get away from everything; he saw B.'s face coming nearer and nearer, until he himself "shrunk to a pin's head," and his brother's face, to use his own words, "went right in." When the patient revived these memories under hypnosis I noticed a peculiar change in his voice and manner. He described how he went to Bletchley, walked to Rugby till almost exhausted, thence took the train to Preston, where he had some food, next he went to Carlisle and back again to Fleetwood. Here he walked about in the rain, cold and tired, until he fell down unable to go farther. The next thing he remembered was waking up in hospital at Fleetwood, where he remained for three weeks. This incident brought him some amount of notoriety, as it was reported in a daily newspaper. Under hypnosis he revived much conflict about killing his wife and children and trying to get to Blackpool, the sea, as usual, suggesting peace and escape. This attack of wandering happened after a holiday spent with his wife and family at Yarmouth. Two interesting sidelights were thrown on this Fleetwood affair under hypnosis: firstly, his last memory of his brother B. was his seeing him off to the front at King's Cross Station and watching his face receding in the distance as the train went out, just as his own face seemed to recede when B.'s came to "go right into him." Secondly, he was brought back to everyday reality at Fleetwood by hearing a child cry and being reminded of his own children.

Dream Symbolism.

I ascertained that this patient's dreams were full of homosexual symbolism. For instance, he dreamed of being chased by a bull with short, thick horns; the bull was on

the other side of a stile and B. was protecting him from it. It had big, round eyes—B.'s eyes. Another time he dreamed of entering a house and hearing that his wife was dead. When he went up to her room it was B. who lay on the bed. B. was quite black all over. He told the patient that he had taken his wife away because he was so unkind to her, and he, B., had come to take her place. In the first of these dreams the ambivalent state of the patient's mind is interestingly shown; the bull (homosexual symbol) is attacking him, typifying his repressed homosexual feelings for his brother, shown by the reaction to the repressed wish; at the same time his brother "protects him from himself." In the second dream the symbolism is even more obvious. It is interesting to note how the idea of vicarious suffering on B.'s part, inculcated by years of Christian teaching, had crept into the patient's unconscious self.

Another dream told of his being chased out of his home by men with big sticks and going to his mother for protection, but finding her door locked against him. He then went to a shed on a hill and lay down to sleep. This dream exemplifies a projection of his repressed homosexuality; by defence reaction the emotion "I love the man" becomes "I hate the man"—that is, he hates what he dare not love and ideas of persecution follow. On the other hand, it may typify a wish-fulfilment—i.e., a repressed desire for sexual attack from a man. (The symbolism of the "big stick" is fairly obvious and very common.) In both cases he runs to his mother for protection—either from persecution or from his own conflicting desires—and finding himself locked out finally obtains peace in a shed on the hay.

Conversations under Hypnosis.

The following conversations are reported verbatim. The patient, without any suggestion from me, usually assumed the personality of B. under hypnosis, but whereas this was at one time accompanied by severe anxiety it now costs him no stress whatever.

Oct. 7th, 1921. Q.: Who are you? A.: Don't know.—Q.: Are you happy? A.: No, I am depressed.—Q.: Where do you want to go? A.: To the north; to the sea, so that I can get in a boat and be by myself; so that I cannot get horrible feelings about people. Something is pressing my head now and I cannot bear the noise of a lot of people.—Q.: Do you remember your mother? A.: Yes. She is alive I love her very much.—Q.: Why do you want to go to the sea? A.: It seems so restful. I cannot rest. (Anxiety and cataleptic state.)—Q.: Do you know about your other self? A.: Yes. It is my brother X. (patient's own name).—Q.: What is your name? A.: B. (the name of the dead man). (Great anxiety. I wakened him at this point and he said he had seen B.)

June 7th, 1922. He saw his dead brothers F. and B. walking together. They wanted to go with him to some place. Great anxiety followed. Patient begged them to stop dragging him about. Then he said he had been killed before he had finished his work, and he must go back to Lincoln to do it. Q.: Who killed you? A.: I was standing up; I did not see it come; I must go back to Lincoln.—Q.: Who are you? A.: B. (Great anxiety followed and he struggled.)

June 8th, 1922. Q.: Who are you? A.: X.—Q.: Who were you yesterday? A.: B. came to me and made me lose myself, as he always does. He wants me to go on with his work.

In my attempts to get at the root of his parental fixations and of his identification with his brother, I carried him back very far into his past by suggesting to him, under hypnosis, that he should remember various red-letter occasions of a child's life. The results were interesting in the extreme: he talked in childish terms and tones; he recalled birthday presents, sweetmeats and toys, during his third and fourth year, and games with his family. Reviving his first birthday, the patient saw his father bending over him; he was dressed as a soldier but not a soldier of to-day. Inquiry elicited the fact that at this time his father was a Volunteer.

At one time, under hypnosis, the patient said that B.'s face was coming towards him; on being asked to touch it he did so and his hand came closer and closer until it touched his own face. He always describes B.'s face as bluish-white. When he was blown up in France he saw a man with a bluish-white face lying on a stretcher. While in hospital at Hemel Hempstead he saw a man in bed with a repulsive face; he frequently confuses these three faces when asked if it is B.'s face that he can see.

Commentary.

Several points of interest emerge from this case. First, the patient is now in good health and has had no trouble since August, 1922, but for reasons I shall state I cannot feel that the improvement is permanent. He called on me during the first week in April of this year and seemed very cheerful and well in hand.

What are called "fixed" symbols enter into this case a great deal. The patient's whole life is a conflict between everyday reality and his forced accommodation to its demands reacting in a desire to return to the infantile or pre-natal state of rest with the mother. So ships, trains, the sea—things great and powerful that will hold him and carry him about without his volition—attract him immensely. It is noticeable that he always tries to run away by one of these means—train, ship, or sea—after an attempt to accommodate himself to the herd by being happy with his wife on a holiday—that is to say, he has been superficially and consciously happy; unconsciously he has been unhappier, more dissatisfied than ever, and must get away from the wife who has been the innocent cause of the strife. Of course, sexual happiness and satisfaction with a woman would always react in severe stress, conscious or otherwise, in a man with a strong mother-fixation; his normal erotism demands sexual satisfaction from the woman he loves; his fixed, infantile impression of woman as the mother makes him deeply dissatisfied with and anxious to escape even from thought of the woman who has departed so naturally from this ideal of his at his own need and demand. In some such cases, where the conflict is not very severe and the sufferer from it in fairly normal mental health, the only result is the abrupt ending of a love affair to the pain and bewilderment of both man and woman. In other cases, where the conflict is so serious as in the case of X., he takes refuge from his unbearable unhappiness in a psychoneurosis which brings about amnesia.

Cases of true dissociated personality are extremely rare, and it is considered almost impossible to bring about complete cure; fusion of the two personalities can be brought about up to a certain point; this point is determined in every case of dissociation by the causation and the gravity of the effects of splitting on each separate occasion—that is to say, a case of dissociation is like a chain with hooks at every link, each link or disunion adding to the weight of conflict and dissociation the patient has to carry. Morton Prince is opposed to what he calls "attempts of a Dionysian psychology" to refer the dissociation to a single unconscious wish either sexual or pleasure-seeking. The case of X. seems to bear out Morton Prince's opinion in this particular.

Genesis of Dissociation.

The dissociation in this case comes about through the patient's parental fixations, and to a certain point typical of these fixations both in circumstance and result; we get the stern father, in this case doubly endowed with attributes of fear by his own characteristics and by his policeman's position and uniform; we get the idolising mother lavishing her middle-aged love on the babe of her brood; we get an exceptionally religious household with strict ideals of duty to God and the nation, as is shown by the careers chosen by the patient's brothers and sisters (army, police, or religious careers for the most part). We get the patient's mother-fixation, first of all in the fact that his only sexual outlet is a homosexual attachment to his brother so strongly repressed as to be symbolised almost out of recognition, as such an attachment could be in this household of law, order, religion, and family affection. The patient's horror at his army companions' coarse jokes about marriage shows that he had not had the young man's usual experiences. There is strong, unconscious attachment to his brother as instinctive and aesthetic on the sexual side, and unconscious on the normal, affectionate family side, yet there is such strong unconscious sexual conflict that his first splitting of personality coincides with his first attempt to obey the herd instinct in thinking of marriage, hesitating about it in his desire to please his mother, urged to it by his love for the girl, repelled from it by coarse suggestions about marriage and by his own quite unrealised fixation on himself—i.e., the Man as opposed to the Woman. And at this point in the patient's history the beloved brother dies! That is to say, he, the brother, ceases from conflict.

B., the brother, is not worried by desire for marriage and revulsion from marriage because B. is dead! X., being still in the land of the living, has all these conflicts to bear. What more natural, then, than that he should seek to end his conflicts by suicide or, failing that and being endowed with a fluid personality, take on the character of the dead brother and thus attempt to find rest for himself? The case of X. appears to be a constant history of defence reaction; from birth up to the moment of conflict in the camp at Shoreham, when marriage was approaching, this patient's history is typical of hundreds of others, most of whom are alcoholics, drug-takers, religious maniacs, or psychoneurotics of some type or other—men afflicted with a mother-fixation and its attendant tendency to homosexuality, with its legacy of rushes into sex adventure from which they emerge broken; men unable to accommodate themselves to normal life. If his brother had not died at that particular moment what would X.'s subsequent history have been? It is useless to speculate. The case is disappointing from the point of view of result; he has transferred his parental fixations to me and depends on me far too much, although while I was away for four weeks in January of this year he did not have a breakdown. I am hoping that I may be able to get him fixed up in work in Australia, where I feel that complete change of environment and the interest of a new life will maintain the improvement he now shows. But I wish to make it quite clear that I know that I have treated this case wrongly; yet I had no alternative. It is necessary, in the case of a working man with dependents, in a country already overburdened with invalids, to patch a man up so that he may earn his bread and carry on his daily life as well as possible. Hypnosis was my only means of getting quickly at the roots of his trouble; if he had been a man of the leisured class who could have afforded the time I should never have thought of hypnosis. Long and detailed analysis is the only radical cure, but once having begun by hypnosis one has to continue, with the result that the patient depends on his physician.

Clinical and Laboratory Notes.

A CASE OF

COEXISTING UTERINE AND ECTOPIC GESTATIONS.

By J. ALLAN BERRY, M.S. DURH., F.R.C.S. EDIN.,
SUPERINTENDENT, NAPIER HOSPITAL, NAPIER, NEW ZEALAND.

IN 1913 Neugenbauer collected from the literature of the subject 243 cases of an ectopic and a uterine gestation occurring at the same time. Since then only about half a dozen cases have been recorded; one of the most recent cases is described by Stropini,¹ who believes the occurrence to be not infrequent.

The following is a record of a case with this very interesting association.

History.—A married woman, aged 26, was admitted to the Napier Hospital on Oct. 22nd, 1922, with the diagnosis of ectopic gestation. Her eldest children are male twins 5 years old, and her other child is a boy aged 3½ years. An aunt of her mother's had two sets of twins. On July 7th, 1921, she had been curetted, following a miscarriage. A month after the operation there was a menstrual period lasting about five days instead of her usual three days, and associated with considerable malaise and some pain which necessitated her going to bed. Following the next period a month later there was a blood-stained vaginal discharge which was intermittent and persisted up to the time of admission. During this time there was very severe abdominal pain associated with sacral backache. On examination there was tenderness most marked in the left lower quadrant of the abdomen, with some rigidity. On vaginal examination a mass was felt in the pouch of Douglas, extending into the

¹ Annali di Ostetricia e Ginecologia, November, 1921.

left lateral fornix. The temperature, pulse, and respiration rates were normal.

Operation.—On Oct. 25th, 1922, the abdomen was opened and the left tube was found to be distended in its ampullary portion with blood-clot, which had evidently ruptured through the ostium, forming an incomplete tubal abortion. The blood-clot had become partly organised and the raw surface left after its removal was covered by bringing part of the mesosigmoid over it. On removing the tube a small interstitial cyst was found on the uterine side of the ectopic gestation. The uterus was noted to be about the size of a three months pregnancy. The left ovary was normal. The right ovary contained a cyst nearly the size of a golf ball, which was removed by a wedge-shaped section and found to be a lutein cyst containing clear fluid. The surface of the section showed another normal-looking corpus luteum. The appendix, which contained some concretions, was removed and the abdomen closed.

On the 27th the patient began to lose blood and blood-clots per vaginam, and on the 31st aborted a three months embryo with membranes complete. Convalescence was uneventful, and she was discharged on Nov. 18th.

Remarks.

The rules laid down by Bichet and Costa in dealing with this condition are agreed to by Stropini in the article already mentioned,¹ and are as follows: (1) When both embryos are living during the earlier months of pregnancy the ectopic gestation should be removed; (2) when the extra-uterine foetus is alive in the later months of pregnancy expectant treatment should be adopted, followed by laparotomy at the commencement of labour; (3) when the ectopic foetus is dead treatment should be as in simple extra-uterine gestation.

It seems possible in the case recorded that if the cystic condition of the right ovary had not been interfered with abortion would not necessarily have followed the operation.

A NOTE ON

SYPHILIS IN SONTIUM IN SCHOOL-CHILDREN.

By H. SHEASBY, M.B., CH.B. BIRM., D.P.H.,

ASSISTANT MEDICAL OFFICER OF HEALTH, CITY AND PORT OF CARDIFF; ASSISTANT, CARDIFF V.D. CLINICS.

THE following three cases of accidental acquired syphilis which were recently seen at the Cardiff School Clinic are recorded as pointing to the prevalence of this condition in children and the possibility of the disease being overlooked:—

A boy, aged 13, was brought by his sister who said he had ringworm. On further questioning she stated he had sores between his legs and that there had been a sore there some three months previously for which ointment had been used. On examination he was found to have very marked syphilitic alopecia, anal condylomata, and general adenitis. Wassermann + + +.

A boy, aged 13, was reported as suffering from impetigo and ringworm and had been treated as such for some weeks. There was a somewhat indefinite history of a sore on the tongue four months previously. At the time of examination alopecia was very marked and there was a serpiginous scaly rash on scalp, trunk, and limbs, impetiginised in places, especially on the scalp. General adenitis. Wassermann + + +.

A boy aged 12. Mother stated he had chicken-pox (? pustular syphilide) a week or ten days ago; now complained of ringworm and sores on his body. On examination he showed a copper-coloured squamous syphilide resembling psoriasis, impetiginised areas on scalp, alopecia, general adenitis, ulcerated mouth and left tonsil. Wassermann + + +. The mother remembered the boy having a sore in his mouth and swollen glands in the neck some months ago.

All the cases cleared up rapidly after a course of N.A.B. injections and hyd. c. cret. at the V.D. clinic. The source of infection was not definitely traced in any of these cases, although the home condition of one of the boys was very unsatisfactory. The superficial resemblance which the cases showed to ringworm, impetigo, and psoriasis diverted attention from the possibility of secondary syphilis, and it was only after a more complete examination that the true nature of the disease was established.

Medical Societies.

SOCIETY OF MEDICAL OFFICERS OF HEALTH: INFECTIOUS DISEASES GROUP.

A DISCUSSION ON BED ISOLATION.

At the annual meeting of this Group, held at 1, Upper Montague-street, Russell-square, London, W.C., on May 25th, Dr. E. W. GOODALL being in the chair, Dr. FREDERIC THOMSON opened a discussion on Bed Isolation and the Conveyance of Infection within a Ward by the reading of a paper which appears in full on another page.

Experience at the North-Western Fever Hospital.

Dr. GOODALL, from the chair, emphasised the necessity, on the part of observers recording experiences of different methods of isolation, of giving full particulars in respect of the ages of the patients, length of time they were in the ward, previous infectious diseases from which they had suffered, the stage of the infectious disease for which they were admitted, the number of cases treated in the ward, the number of beds, and the number of staff employed. It was not sufficient merely to state that so many patients had been treated in the ward and that so many had caught or had not caught an infectious disease. While Dr. Thomson and Dr. MacIntyre had given most of the details referred to, some observers had omitted to do so; but every one of these details was of importance in coming to any conclusion as to results. There was a ward of 20 beds for bed isolation at the North-Western Hospital; 900 patients had been treated in this ward from Jan. 1st, 1920, to the beginning of May, 1923. There had been 31 cases of cross infection during that period in the ward, or 3·4 per cent. Of these 9 had been cases of measles, 6 of chicken-pox, 7 of scarlet fever, 6 of diphtheria, 2 of whooping-cough, and 1 of rubella. No case of chicken-pox or measles had been deliberately placed in the ward. The cases of these diseases had arisen subsequently to the development of one case of each disease in a patient who was admitted unwittingly in the incubation stage and upon the only occasions on which such cases had been introduced into the ward. A large number of mild cases of scarlet fever, diphtheria, whooping-cough, and rubella had been under treatment in the ward. As regards the number of patients protected by previous attacks of infectious diseases, Dr. Goodall stated that of 1000 consecutive cases which had been treated in the isolation chambers at the Eastern Hospital some years ago, 63 per cent. had previously had measles, 25 per cent. chicken-pox, 24 per cent. scarlet fever, 20 per cent. whooping-cough, and 16 per cent. diphtheria; 94 per cent. of the 1000 cases were under 10 years of age. The information as to previous attacks had been obtained from the parents. From the evidence obtained from the numbers of these cases which had caught infection in the chambers, he had come to the conclusion that chicken-pox was the most infectious of the diseases treated, measles the next, and then scarlet fever, whooping-cough, and diphtheria in the order given. He agreed with Dr. Thomson that measles and chicken-pox were most infectious during the early stages. He knew of two instances in which patients suffering from chicken-pox in the scabbing stage had been admitted to children's wards with no spread of the infection. He understood that Dr. Thomson's opinion was that chicken-pox was infectious only so long as vesicles were present. If that were so, chicken-pox might remain infectious for longer than four days, as occasionally vesicles continued to come out for several days. Excluding the cases of measles and chicken-pox, the incidence of cross infection in the ward at the North-Western Hospital was 1·7 per cent. He had not insisted upon the windows being open in this ward. Dr. Thomson made a brief allusion to wards containing separate

chambers with a central corridor. He, Dr. Goodall, had also considerable experience of this method of isolating cases. He had succeeded on several occasions in nursing acute cases of chicken-pox in these wards without the spread of infection, but on other occasions infection had spread. He was inclined in some instances to attribute this spread to some omission on the part of the staff. After all, the success of the methods depended very largely upon the staff. He had not that afternoon heard any facts which led him to alter the conclusion he had come to some time ago, that it was unsafe to treat *all* cases of measles and chicken-pox, and *most* severe cases of scarlet fever, diphtheria, and whooping-cough in bed isolation wards, during the acute stage of the disease.

Experience at Plaistow.

Dr. D. MACINTYRE remarked that a great deal had yet to be learnt regarding the control of infection. All who had done bed isolation work appeared to have experienced some cross infection, the results obtained by Dr. Rundle being the nearest approach to complete success. At the same time he considered that work along bed isolation lines was of the greatest value, not only from the point of view of treating different infections in one ward, but as a means of preventing cross infection in the main wards of an isolation hospital. He was of opinion that droplet and aerial infection were not the only or even the greatest source of danger in a well-ventilated ward. In an operating theatre the surgeon took every precaution against carrying infection by his hands or instruments, &c., but paid little or no attention to the air of the theatre, and it could be imagined there was some risk of the wound becoming infected from the air, but evidently it did not. It seemed to him that the success of a bed isolation ward depended mainly on how far the surgeon's standard of cleanliness was carried out with regard to all feeding and nursing utensils, and of almost equal importance was the free ventilation of the ward. Another important point was to limit the number of articles in use to the bare minimum and reduce the system of nursing to as simple a form as possible. With regard to nursing staff, he felt satisfied that the average class of nurse could be relied on to carry out her work efficiently. At Plaistow the nurses were taught the meaning of surgical cleanliness from the outset and the vital importance of all details of the routine was constantly impressed upon them by the sister, and his experience was that they carried out their duties conscientiously. With regard to the measles cross infection at Plaistow, referred to by Dr. Thomson, though he was not certain on the point, it was quite possible these cases were caused by some of the patients admitted before the onset of the eruption. At the present time chicken-pox patients were not receiving any special treatment to the skin. Two had been admitted recently on the first day of disease and none had cross-infected. Referring to cubicle and cell wards, he emphasised the danger of infection spreading through the opening and shutting of doors by the nursing staff. In bed isolation wards his danger was eliminated, and further, there was the opportunity for a continual current of fresh air.

Experience at Fazakerley.

Dr. C. RUNDLE, who had received an advance copy of Dr. Thomson's paper, wrote as follows: It is very clear that Dr. Thomson's results are quite different from ours, but the explanation is less obvious. Since the army figures at Fazakerley must run into a thousand or more above those already published, with a cross-infection rate which is really negligible; in fact, from memory I can only recall two cases. My bed isolation wards are regarded as the most safe of all. As an example of how our own staff see the matter, one of our assistant matrons persuaded me to admit her nephew for a particular asthma treatment. The child, aged 2 years, had had no infectious disease, but by her special request was admitted to a bed isolation ward rather than an isolation or side ward. When I have a little more time I hope to produce a return including all the facts of which Dr. Thomson speaks in

his paper. The following points may account for a good deal: 1. The dilution of our cases with adults. 2. The fact—suggested in Dr. Thomson's paper—that mine are chiefly from outside, and consequently somewhat later in their stage of illness than his. 3. My object has been to extend the usefulness of the hospital in as many directions as possible, compatible with the safety of my patients, and every device possible has been employed to avoid unnecessary risks. Dr. Thomson, on the other hand, has deliberately, in the interests of scientific investigation, placed every conceivable strain on his system by a selection of cases at the most infectious stage and susceptible age, with no diluents in the shape of adults or negative cases. Is it really surprising that our results are incompatible? Does not the fact of the sporadic character of Dr. Thomson's outbreaks suggest a fault in technique? It seems to me that the human factor is more likely to be the cause of variability than aerial transmission if it exists. The only proof of this would be an exchange of nursing staff. Finally, let me say that this human factor is always present in my mind. Bed isolation is utilised at Fazakerley for the reception of cases for which no ward is open at the time. For instance, at the moment we have so many cases of varicella and measles that special wards are in use, and there is not a single case in the bed isolation wards. As, however, the outbreaks subside, these wards will close and individual cases will again be sent to the bed isolation wards.

Experience at Edinburgh.

Dr. C. B. KER also wrote: I am glad to be allowed to contribute to a discussion which I cannot, unfortunately, attend. I cannot speak with any authority on the subject, as here in Edinburgh I have never run a bed isolation ward. I find it very difficult to define when droplet infection ends and aerial infection begins, but I would be inclined to call infection occurring in a closed space like a ward droplet rather than aerial. I must confess to having always inclined to the belief that contact infection is the point of most importance, and have been very sceptical of the carriage of droplets for any distance. Such carriage, however, is conceivable and probably occurs under suitable conditions in wards which are not too large, but again the question as to whether a suitable infecting dose is often likely to be carried as far as the length of a ward is another matter altogether. I am quite prepared to believe it occasionally occurs if air currents are particularly suitable. It will be remembered that Armstrong was unable to establish that measles carried more than nine feet in the school chapel at Wellington. Evidence of infection within that distance was definite enough, and yet measles is aided by forcible sneezing, which surely must propel droplets as far as any other method of dissemination. No doubt the droplets do go a greater distance, but are they so scattered as not to carry an infective dose? On the other hand, assuming that there are no errors in technique, and I quite believe that, if there are any in Dr. Rundle's or Dr. Thomson's wards, they are extremely rare—it is extremely difficult to get over Dr. Thomson's experience of chicken-pox without admitting that, indoors at least, the infection can be air-borne. In this connexion I remember being very much impressed by the experience of Dr. Peters at Bristol, who reported that widely opened windows, winter and summer, appeared to prevent the spread of chicken-pox, and that children incubating the disease in his wards did not transmit the disease in. I think, over 20 consecutive instances. I remember in one summer I had six consecutive introductions of chicken-pox to a whooping-cough ward in this manner without a secondary case, an experience I have never had before or since. The children in this case had 15 ft. of wall space, and the windows between them would always be open, usually widely open. One cannot escape from the suggestion that the free cross-ventilation may so break up aerial currents in the ward as to protect the patients, and I have always regarded Dr. Peters's results as the strongest
